List Number: 1
Creator: Scott, Sherri L

Question	Answer	Comment
Radioactivity wasn't checked or is </= background as measured by a survey meter.	True	
The cooler's custody seal, if present, is intact.	True	
Sample custody seals, if present, are intact.	True	
The cooler or samples do not appear to have been compromised or tampered with.	True	
Samples were received on ice.	True	
Cooler Temperature is acceptable.	True	
Cooler Temperature is recorded.	True	0.5,2.6
COC is present.	True	
COC is filled out in ink and legible.	True	
COC is filled out with all pertinent information.	True	
Is the Field Sampler's name present on COC?	True	
There are no discrepancies between the containers received and the COC.	False	Received Trip Blank(s) not listed on COC.
Samples are received within Holding Time (excluding tests with immediate HTs)	True	
Sample containers have legible labels.	True	
Containers are not broken or leaking.	True	
Sample collection date/times are provided.	True	
Appropriate sample containers are used.	True	
Sample bottles are completely filled.	True	
Sample Preservation Verified.	True	
There is sufficient vol. for all requested analyses, incl. any requested MS/MSDs	True	
Containers requiring zero headspace have no headspace or bubble is <6mm (1/4").	True	
Multiphasic samples are not present.	True	
Samples do not require splitting or compositing.	True	
Residual Chlorine Checked.	N/A

The test results in this report meet all 2003 NELAC and 2009 TNI requirements for accredited parameters, exceptions are noted in this report. This report may not be reproduced except in full, and with written approval from the laboratory. For questions please contact the Project Manager at the e-mail address or telephone number listed on this page.

This report has been electronically signed and authorized by the signatory. Electronic signature is intended to be the legally binding equivalent of a traditionally handwritten signature.

Results relate only to the items tested and the sample(s) as received by the laboratory.

Narrative

Job Narrative
500-169224-1

Comments
No additional comments.

Receipt
The samples were received on 8/29/2019 9:30 AM; the samples arrived in good condition, properly preserved and, where required, on ice. The temperature of the cooler at receipt was 5.1° C.

GC/MS VOA
The following sample was collected in properly preserved vials for analysis of volatile organic compounds (VOCs). However, the pH was outside the required criteria when verified by the laboratory, and corrective action was not possible: TW15 (500-169224-4).

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

GC/MS Semi VOA
Method(s) 8270D: The following sample was diluted due to the nature of the sample matrix: TW15 (500-169224-4). Elevated reporting limits (RLs) are provided.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Metals
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

Field Service / Mobile Lab
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

Organic Prep
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

Project/Site: Fox Shores Apt. Kaukauna - 193706620

Qualifiers

GC/MS VOA

Qualifier	Qualifier Description
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

GC/MS Semi VOA

Qualifier	Qualifier Description
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Metals

Qualifier	Qualifier Description
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
¤	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
PQL	Practical Quantitation Limit
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)

Login Sample Receipt Checklist

Client: Stantec Consulting Corp. Job Number: 500-169224-1

Login Number: 169224 **List Source: Eurofins TestAmerica, Chicago**
List Number: 1
Creator: Buckley, Paula M

Question	Answer	Comment
Radioactivity wasn't checked or is </= background as measured by a survey meter.	True	
The cooler's custody seal, if present, is intact.	True	
Sample custody seals, if present, are intact.	True	
The cooler or samples do not appear to have been compromised or tampered with.	True	
Samples were received on ice.	True	
Cooler Temperature is acceptable.	True	
Cooler Temperature is recorded.	True	5.1
COC is present.	True	
COC is filled out in ink and legible.	True	
COC is filled out with all pertinent information.	True	
Is the Field Sampler's name present on COC?	True	
There are no discrepancies between the containers received and the COC.	True	
Samples are received within Holding Time (excluding tests with immediate HTs)	True	
Sample containers have legible labels.	True	
Containers are not broken or leaking.	True	
Sample collection date/times are provided.	True	
Appropriate sample containers are used.	True	
Sample bottles are completely filled.	True	
Sample Preservation Verified.	True	
There is sufficient vol. for all requested analyses, incl. any requested MS/MSDs	True	
Containers requiring zero headspace have no headspace or bubble is <6mm (1/4").	N/A	
Multiphasic samples are not present.	True	
Samples do not require splitting or compositing.	True	
Residual Chlorine Checked.	N/A

The test results in this report meet all 2003 NELAC and 2009 TNI requirements for accredited parameters, exceptions are noted in this report. This report may not be reproduced except in full, and with written approval from the laboratory. For questions please contact the Project Manager at the e-mail address or telephone number listed on this page.

This report has been electronically signed and authorized by the signatory. Electronic signature is intended to be the legally binding equivalent of a traditionally handwritten signature.

Results relate only to the items tested and the sample(s) as received by the laboratory.

Comments
No additional comments.

Receipt
The samples were received on 4/17/2020 9:45 AM; the samples arrived in good condition, properly preserved and, where required, on ice. The temperatures of the 2 coolers at receipt time were 0.5º C and 2.6º C.

Receipt Exceptions
A trip blank was submitted for analysis with these samples; however, it was not listed on the Chain of Custody (COC). Added to COC and logged in.

GC/MS VOA
Method 8260B: The laboratory control sample (LCS) for batches 539816 and 539811 recovered outside control limits for Bromomethane. This analyte was biased high in the LCSs and was not detected in the associated samples; therefore, the data have been reported.HA-1 (500-180867-1), HA-2 (500-180867-2), HA-3 (500-180867-3), HA-4 (500-180867-4), HA-5 (500-180867-5), HA-6 (500-180867-6), HA-7 (500-180867-7), HA-8 (500-180867-8), HA-9 (500-180867-9), HA-10 (500-180867-10), HA-11 (500-180867-11), HA-12 (500-180867-12), TW-10 (500-180867-14), TW-11 (500-180867-15), TW-13 (500-180867-16), TW-15 (500-180867-17), TW-17 (500-180867-18) and Trip Blank (500-180867-19)

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

GC/MS Semi VOA
Method 8270D: The following samples were diluted due to the nature of the sample matrix: HA-2 (500-180867-2), HA-3 (500-180867-3), HA-4 (500-180867-4), HA-5 (500-180867-5), HA-6 (500-180867-6), HA-10 (500-180867-10) and HA-11 (500-180867-11). Elevated reporting limits (RLs) are provided.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Metals
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

Field Service / Mobile Lab
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

Organic Prep
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

Qualifiers

GC/MS VOA

Qualifier	Qualifier Description
*	LCS or LCSD is outside acceptance limits.
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

GC/MS Semi VOA

Qualifier	Qualifier Description
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Metals

Qualifier	Qualifier Description
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
¤	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
PQL	Practical Quantitation Limit
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)

Question	Answer	Comment
Radioactivity wasn't checked or is </= background as measured by a survey meter.	True	
The cooler's custody seal, if present, is intact.	True	
Sample custody seals, if present, are intact.	True	
The cooler or samples do not appear to have been compromised or tampered with.	True	
Samples were received on ice.	True	
Cooler Temperature is acceptable.	True	
Cooler Temperature is recorded.	True	0.5,2.6
COC is present.	True	
COC is filled out in ink and legible.	True	
COC is filled out with all pertinent information.	True	
Is the Field Sampler's name present on COC?	True	
There are no discrepancies between the containers received and the COC.	False	Received Trip Blank(s) not listed on COC.
Samples are received within Holding Time (excluding tests with immediate HTs)	True	
Sample containers have legible labels.	True	
Containers are not broken or leaking.	True	
Sample collection date/times are provided.	True	
Appropriate sample containers are used.	True	
Sample bottles are completely filled.	True	
Sample Preservation Verified.	True	
There is sufficient vol. for all requested analyses, incl. any requested MS/MSDs	True	
Containers requiring zero headspace have no headspace or bubble is <6mm (1/4").	True	
Multiphasic samples are not present.	True	
Samples do not require splitting or compositing.	True	
Residual Chlorine Checked.	N/A

The test results in this report meet all 2003 NELAC and 2009 TNI requirements for accredited parameters, exceptions are noted in this report. This report may not be reproduced except in full, and with written approval from the laboratory. For questions please contact the Project Manager at the e-mail address or telephone number listed on this page.

This report has been electronically signed and authorized by the signatory. Electronic signature is intended to be the legally binding equivalent of a traditionally handwritten signature.

Results relate only to the items tested and the sample(s) as received by the laboratory.

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
¤	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
PQL	Practical Quantitation Limit
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)

Case Narrative

Client: Stantec Consulting Corp.

Narrative

Job Narrative
200-47582-1

Comments
No additional comments.

Receipt
The samples were received on 2/27/2019 10:35 AM; the samples arrived in good condition, properly preserved and, where required, on ice.

Air Toxics
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

Detection Summary

Client: Stantec Consulting Corp.
Project/Site: Fox Shores Apts - 193706620

TestAmerica Job ID: 200-47582-1

Client Sample ID: VP-4 AMBIENT — Lab Sample ID: 200-47582-1

Analyte	Result	Qualifier	RL	MDL	Unit	Dil Fac	D	Method	Prep Type
Dichlorodifluoromethane	3.9		0.50	0.056	ppb v/v	1		TO-15	Total/NA
Dichlorodifluoromethane	19		2.5	0.28	ug/m3	1		TO-15	Total/NA

Question	Answer	Comment
Radioactivity wasn't checked or is </= background as measured by a survey meter.	True	Lab does not accept radioactive samples.
The cooler's custody seal, if present, is intact.	True	Not present
Sample custody seals, if present, are intact.	True	
The cooler or samples do not appear to have been compromised or tampered with.	True	
Samples were received on ice.	N/A	Thermal preservation not required.
Cooler Temperature is acceptable.	True	
Cooler Temperature is recorded.	N/A	Thermal preservation not required.
COC is present.	True	
COC is filled out in ink and legible.	True	
COC is filled out with all pertinent information.	True	
Is the Field Sampler's name present on COC?	True	
There are no discrepancies between the containers received and the COC.	True	
Samples are received within Holding Time (excluding tests with immediate HTs)	True	
Sample containers have legible labels.	True	
Containers are not broken or leaking.	True	
Sample collection date/times are provided.	True	
Appropriate sample containers are used.	True	
Sample bottles are completely filled.	N/A	
Sample Preservation Verified.	True	
There is sufficient vol. for all requested analyses, incl. any requested MS/MSDs	True	
Containers requiring zero headspace have no headspace or bubble is <6mm (1/4").	True	
Multiphasic samples are not present.	True	
Samples do not require splitting or compositing.	True	
Residual Chlorine Checked.	N/A

[1] Batch Certification: The reading is taken on the "batch" canister and this value is used as the initial pressure for all canisters in the batch.

[3] Difference = Final Pressure - Initial Pressure . Acceptance Criteria: (1) The difference must be less than or equal to + 0.25psi. (2) Pressure readings must be at least 24 hours apart.

If time frame was not met, the PM must authorize shipment of canister **PM Authorization** **Date:**

Project/Site: Fox Shores Apt - 193706620

Job ID: 140-16324-1

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
¤	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
PQL	Practical Quantitation Limit
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)

Laboratory: Eurofins TestAmerica, Knoxville

Narrative

Job Narrative
140-16324-1

Comments
No additional comments.

Receipt
The samples were received on 8/14/2019 10:00 AM; the samples arrived in good condition, properly preserved and, where required, on ice.

Receipt Exceptions
The container label for the following samples did not match the information listed on the Chain-of-Custody (COC): VP-4 (140-16324-1), VP-5 (140-16324-2) and VP-6 (140-16324-3). The container labels are blank; the samples were matched by the Canister IDs, and labeled per the Chain-Of-Custody.

Air - GC/MS VOA
Method(s) TO 15 LL, TO-14A, TO-15: EPA methods TO-14A and TO-15 specify the use of humidified "zero air" as the blank reagent for canister cleaning, instrument calibration and sample analysis. Ultra-high purity humidified nitrogen from a cryogenic reservoir is used in place of "zero air" by Eurofins TestAmerica Knoxville.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Detection Summary

Client: Stantec Consulting Corp.
Project/Site: Fox Shores Apt - 193706620

Job ID: 140-16324-1

Client Sample ID: VP-4 — Lab Sample ID: 140-16324-1

Subject: Phase II Subsurface Investigation Report
Fox Shores Apartments
400 Fox Shores Drive
Kaukauna, Wisconsin 54130
Partner Project Number: 18-215232.3

Dear Mr. LaCroix:

Partner Engineering and Science, Inc. (Partner) is pleased to provide the results of the assessment performed on the above-referenced property. The following report describes the field activities, methods, and findings of the Phase II Subsurface Investigation conducted at the above-referenced property.

This assessment was performed utilizing methods and procedures consistent with good commercial or customary practices designed to conform to acceptable industry standards. The independent conclusions represent Partner's best professional judgment based upon existing conditions and the information and data available to us during the course of this assignment.

We appreciate the opportunity to provide these services. If you have any questions concerning this report, or if we can assist you in any other matter, please contact Scott Chiu at (214) 234-9561.

Sincerely,

Partner Engineering and Science, Inc.

1.0 INTRODUCTION

1.1 Purpose

The purpose of the investigation was to evaluate the potential impact of volatile organic compounds (VOCs), polycyclic aromatic hydrocarbons (PAHs), and/or metals to soil gas, soil, and/or groundwater as a consequence of a release or releases from the general historical former industrial use of the subject property and/or CREC sites. Berkadia Commercial Mortgage LLC provided project authorization of Partner Proposal Number P18-215232.3.

1.2 Limitations

This report presents a summary of work conducted by Partner. The work includes observations of site conditions encountered and the analytical results provided by an independent third party laboratory of samples collected during the course of the project. The number and location of samples were selected to provide the required information. However, it cannot be assumed that the limited available data are representative of subsurface conditions in areas not sampled.

Conclusions and/or recommendations are based on the observations, laboratory analyses, and the governing regulations. Conclusions and/or recommendations beyond those stated and reported herein should not be inferred from this document.

Partner warrants that the environmental consulting services contained herein were accomplished in accordance with generally-accepted practices in the environmental engineering, geology, and hydrogeology fields that existed at the time and location of work. No other warranties are implied or expressed.

1.3 User Reliance

Partner was engaged by Berkadia Commercial Mortgage LLC (the Addressee), or their authorized representative, to perform this investigation. The engagement agreement specifically states the scope and purpose of the investigation, as well as the contractual obligations and limitations of both parties. This report and the information therein, are for the exclusive use of the Addressee. This report has no other purpose and may not be relied upon, or used, by any other person or entity without the written consent of Partner. Third parties that obtain this report, or the information therein, shall have no rights of recourse or recovery against Partner, its officers, employees, vendors, successors or assigns. Any such unauthorized user shall be responsible to protect, indemnify and hold Partner, the Addressee and their respective officers, employees, vendors, successors and assigns harmless from any and all claims, damages, losses, liabilities, expenses (including reasonable attorneys' fees) and costs attributable to such use. Unauthorized use of this report shall constitute acceptance of, and commitment to, these responsibilities, which shall be irrevocable and shall apply regardless of the cause of action or legal theory pled or asserted.

This report has been completed under specific Terms and Conditions relating to scope, relying parties, limitations of liability, indemnification, dispute resolution, and other factors relevant to any reliance on this report. Any parties relying on this report do so having accepted Partner's standard Terms and Conditions, a copy of which can be found at http: / www.partneresi.com/terms-and-conditions.php

2.0 SITE BACKGROUND

2.1 Site Description

The subject property consists of three parcels of land comprising 2.185 acres located to the north and west of Fox Shores Drive within a mixed commercial and residential area of Kaukauna, Wisconsin. The subject property is currently occupied by the Fox Shores Apartments for residential use. Onsite operations consist of general residential operations and maintenance activities. In addition to the current structures, the subject property is also improved with paved-parking areas and limited landscaping

The subject property is bound by Fox River to the north, Fox Shores Drive beyond which is Ghost Town Fitness Center (180 Fox Shores Drive) to the east, Bicentennial Court beyond which is City of Kaukauna Street and Parks Department operations facility (206 West Third Street and 201 Reaume Avenue) to the south, and River Park Place Apartments (420 Bicentennial Court to the west. Refer to Figure 1 for a site plan showing site features and surrounding properties.

2.2 Site History

Partner completed a *Phase I Environmental Site Assessment Report* (Phase I), dated July 6, 2018, prepared on behalf of Berkadia Commercial Mortgage LLC. According to the reviewed historical sources, the subject property was formerly developed as early as circa 1890. Development activities, as depicted on Sanborn fire insurance maps, indicate the subject property and vicinity were developed as part of the Chicago and Northwest Rail Road Shops. Numerous structures were developed on the subject property between approximately 1890 until at least 1971 per historical aerial imagery. Aerial imagery depicts the site as undeveloped in 1982. Tax assessor documents indicate development of the subject property began in 1983 with the development of the existing multi-family residential structures along Bicentennial Court. A second phase of residential structures were developed in 1992 along Fox Shores Drive.

The 1925 Sanborn map depicts a carpentry shop, machine shop, repair shop, engine room, coal room, blacksmith shop, supply warehouses, tin shop, and pipe shed. It is assumed that these occupants and structures existed at the subject property throughout the period (c. 1890-1971) the subject property was developed for railroad services.

The Phase I identified the following recognized environmental condition (REC) associated with the subject property:

> The west adjacent property, identified as the USACE (United States Army Corps of Engineers) – Parcel J (Kaukauna Power Canal) is an open Environmental Repair Program (ERP) case on the online Wisconsin Bureau for Redevelopment and Remediation Tracking (WI BRRTS) database. The site's address is identified as the "end of 420 Bicentennial Court". The responsible party for this site is listed at the USACE. According to Wisconsin Department of Natural Resources (WDNR) records, the constituent of concern for this site is identified as lead and impacts are known to be present in the soil media. The case was opened and responsible party notified on March 1, 2003. To date, no remedial activities have occurred. Per correspondence with the WDNR case manager assigned to site, the USACE has not made efforts to pursue remediation of the site. Parcel J, as depicted on a sampling map obtained from the WDNR, encompasses the shoreline of the Fox

River beginning to the west of the subject property and extends eastward toward the subject property, ultimately concluding at the northeast corner of the subject property. In total, this site represents the north and northwest adjacent property. Soil sampling results from 2004 and 2005 subsurface investigation indicate elevated levels of lead immediately north and northwest of the subject property boundary along the Fox River shoreline.

Limited information is available for the USACE – Parcel J site given the USACE's denial of responsibility for the contamination to date. Correspondence with WDNR also indicated the site's priority level with the WDNR does not qualify it for State funded remediation. As of the August 9, 2016 semi-annual status report, no action has been taken at the site. The WDNR will continue to issue semi-annual status updates per WDNR policy; however, at this time, no action is anticipated. Based on the known soil contamination abutting the northern and northwestern boundary of the subject property, this site represents a REC.

Two controlled RECs (CRECs) were identified:

1. The property, identified as Ghost Town Fitness Center at 180 Fox Shores Drive, is located adjacent to the east of the subject property and is associated with arsenic and selenium groundwater impact.
2. The property, identified as the Kaukauna Waste Oil Collection Site at 201 West 2nd Street, 222 3rd Street, and 3rd Street 200 Block, and is located adjacent to the south of the subject property beyond Bicentennial Court and is associated with petroleum soil and groundwater impact.

According to a Phase II Subsurface Investigation conducted at the south adjacent property and correspondence with the WDNR, the depth and direction of groundwater in the vicinity of the subject property is inferred to be approximately five feet below ground surface (bgs) and flow toward the southeast

2.3 Geology and Hydrogeology

Based on a review of the United States Geological Survey (USGS) *Kaukauna Wisconsin* Quadrangle topographic map, the subject property is situated at an elevation approximately 657 feet above mean sea level, and the local topography is sloping gently to the southeast. Refer to Figure 2 for a topographic map of the site vicinity.

The subject property is situated within the Eastern Ridges and Lowlands physiographic province of the State of Wisconsin. The topography of the eastern ridges and lowlands is controlled by cuestas. The westernmost ridge is the rather low, narrow cuesta formed by the resistant Lower Magnesian limestone. It is alluded to hereafter as the Magnesian cuesta. The eastern upland is the higher and broader cuesta of Niagara limestone. The intermediate Green Bay- Lake Winnebago- Rock River lowland lies upon the belt of Black River and Galena limestone, with the gentle back slope of the Magnesian cuesta for one wall and the steep escarpment of the Niagara cuesta for the other.

Based on information obtained from the United States Department of Agriculture (USDA) Natural Resources Conservation Service Web Soil Survey online database, the subject property is mapped as Udorthents. Udorthents consists of well drained to excessively drained soils along mainly the southern

edge of Block Island adjacent to Block Island Sound in the Mohegan Bluff area. Wind, waves, and rain have eroded these soils and undercut areas on bluffs. Areas are long and narrow and mostly range from 10 to 200 acres mainly loamy sand, sandy loam and silty clay loam that are well drained with 0 to 5 percent slopes.

Based on borings advanced during this investigation, the underlying subsurface consists predominantly of black clay with some sand and gravel from the ground surface to approximately 6 feet below ground surface (bgs). From 6 feet to 10 feet bgs, the subsurface consists predominantly of brown to gray clay with some sand and gravel. Groundwater was encountered during this investigation between 4.5 and 7 feet bgs.

3.0 FIELD ACTIVITIES

The scope of the Phase II Subsurface Investigation included a limited geophysical survey (boring clearance only), the advancement of five borings (B1 through B5) for the collection of representative soil and groundwater samples, and the installation of three temporary sub-slab soil gas sampling points for the collection of representative soil gas samples. Refer to Table 1 for a summary of the borings, sampling schedule and laboratory analyses for this investigation.

3.1 Preparatory Activities

Prior to the initiation of fieldwork, Partner completed the following activities.

3.1.1 Utility Clearance

Partner subcontracted with the driller Johnson Probing, Inc. (Johnson) who notified Wisconsin Diggers Hotline to clear public utility lines as required by law at least 72 hours prior to drilling activities. Wisconsin Diggers Hotline issued ticket numbers 20183912709 for the project.

In addition, Partner subcontracted with Ground Penetrating Radar Systems, Inc. (GPRS) of Wisconsin on October 3, 2018 to clear boring locations of utilities. GPRS systematically free-traversed each proposed boring location with a Radio-detection model RD7000 electromagnetic induction (EM) equipment unit with line-tracing capabilities, and a GSSI model SIR-3000 ground penetrating radar (GPR) unit. The equipment data were interpreted in real time for evidence of utility lines and/or other subsurface features of potential concern. Borings were positioned based on the geophysical survey results to avoid damaging underground features. No significant boring location limitations were encountered.

3.1.2 Health and Safety Plan

Partner prepared a site-specific Health and Safety Plan, which was reviewed with on-site personnel involved in the project prior to the commencement of drilling activities.

3.2 Drilling Equipment

On October 3, 2018, Partner subcontracted with Johnson to provide and operate drilling equipment. Johnson, under the direction of Partner, advanced five exterior soil borings (B1 through B5) with a Geoprobe model 6610DT. The temporary sub-slab soil gas pins were installed with a hand drill. Drilling rods and sampling equipment were decontaminated between samples and borings to prevent cross-contamination

3.3 Boring Locations

Borings B1 and B2 were advanced respectively at the exterior southeastern and southwestern portions of the subject property in the area of historic industrial operations. Boring B3 was advanced at the exterior west central portion of the subject property in the area of historic industrial operations. Boring B4 was advanced at the exterior northwestern portion of the subject property in the area of historic industrial operations. Boring B5 was advanced at the exterior north central portion of the subject property in the area of historic industrial operations. Given the former general industrial use, the borings were placed to generally cover the extent of the property. Refer to Figure 3 for a map indicating boring locations.

3.4 Soil Sampling

Borings B1 through B4 were each advanced by the direct-push drill rig to a terminal depth of 10 feet bgs. Boring B5 was advanced by the direct-push drill rig to a terminal depth of 7 feet bgs due to probe refusal.

Soil samples were collected using a 5-foot long by 2.25-inch diameter MacroCore sampler with a 5-foot long acetate liner, which was advanced by the direct-push drill rig using 5-foot long by 1.5-inch diameter drill rods. The samplers were driven into the subsurface to allow undisturbed soil to enter the open MacroCore barrel and retrieved to recover the soil-filled liners. A lengthwise section of each acetate liner was removed with a splitting tool to expose the soil and the samples were collected using a stainless spoon. The soil column at each boring was visually inspected for discoloration, monitored for odors, and classified in accordance with the Unified Soil Classification System (USCS). Additionally, the soil column was field-screened with a photoionization detector (PID) calibrated to 100 parts per million (ppm) isobutylene.

Based on borings advanced during this investigation, the underlying subsurface consists predominantly of black clay with some sand and gravel from the ground surface to approximately 6 feet bgs. From 6 feet to 10 feet bgs, the subsurface consists predominantly of brown to gray clay with some sand and gravel. Groundwater was encountered during this investigation between 4.5 and 7 feet bgs.

No visual and olfactory evidence of impacted conditions was detected in any of the borings. PID readings on the soil profile screened from borings B1 through B5 ranged from 0.0 ppm to 0.1 ppm.

Refer to Appendix A for a copy of the soil boring logs.

Soil depths selected for laboratory analysis were sampled directly from the liners using a disposable plastic syringe and retained in two sodium bisulfate-preserved and one methanol volatile organics analysis (VOA) vials in accordance with United States Environmental Protection Agency (EPA) Method 5035 sampling protocol. A soil sample was also collected by transferring soil into a laboratory-supplied, 4-ounce, wide-mouth, unpreserved glass jar, which was sealed with a threaded, Teflon-lined lid for PAHs and Resource Conservation and Recovery Act (RCRA) 8 metals analysis. The jars were filled with soil to capacity to minimize headspace and reduce the potential for volatilization. The jars and VOA vials were labeled for identification and stored in an iced-cooler.

As no staining or elevated PID readings were encountered, soil samples from each boring B1 through B5 were collected from intervals above the groundwater interface from depths between 3 and 8 feet bgs. A surficial soil sample was collected from each boring B1 through B5 at intervals 0.5-1.0 feet bgs (to address the reported metals surficial impacts on the adjacent property).

3.5 Groundwater Sampling

After soil sampling to the terminal depth, groundwater samples were collected by withdrawing the drill rods from the subsurface and installing ¾-inch diameter temporary monitoring wells within the open boreholes of borings B1 through B5. Each monitoring well consisted of a five-foot long, 0.010-inch factory-slotted polyvinyl chloride (PVC) screen at the terminal end and blank PVC risers from the top of the screen interval to the ground surface. New screens, risers, and tubing were used for each temporary monitoring well. Groundwater samples were collected from temporary well points at borings B1 through

B4 screened from 5 feet bgs to 10 feet bgs. Groundwater sample was collected from temporary well point at borings B5 screened from 2 feet bgs to 7 feet bgs

Groundwater samples were retrieved from each monitoring well using a new section of 3/8-inch diameter Teflon tubing fed through a peristaltic pump and conveyed into three hydrochloric acid-preserved and two unpreserved VOA vials and two 250 mL amber jars. Each vial was filled with no observable headspace or air bubbles to minimize the potential for volatilization, labeled for identification, and stored in an iced cooler.

3.6 Sub-Slab Soil Gas Sampling

To facilitate the collection of a soil gas sample from beneath the subject property, temporary sub-slab soil gas sample point VP-1 through VP-3 were advanced using a power hand drill to a depth of 1.0 feet bgs through the floor slab. The sub-slab soil-gas sampling point, consisting of a pre-fabricated stainless steel Vapor Pin™ equipped with a silicone sleeve, was manually inserted into a $^{5}/_{8}$-inch diameter hole drilled through the concrete slab of the subject property building using a rotary hammer drill. After installing the Vapor Pin™ a protective cap was placed over the barbed sampling end of the Vapor Pin™ and a water dam was installed around the Vapor Pin™ to further ensure that an air tight seal was present around the sampling point. Once the air tight seal was confirmed, the water dam was removed and the sample tubing and the Vapor Pin™ were purged of ambient air using a PID. The sampling end of the tubing was initially connected to a PID to field screen the soil-gas conditions relating to VOCs and to purge the sample point. The soil-gas sample point was purged for approximately two minutes. The PID readings were 0.0 ppm. Prior to purging, ambient air quality was monitored at the subject property and PID background reading was 0.0 ppm. After the ambient air was purged from the sample tubing and Vapor Pin™, a connection was made with new Teflon tubing and a laboratory-supplied certified clean 1-liter Summa® canisters equipped with 5.0-minute flow controllers.

Soil gas samples were collected in general accordance with the Wisconsin Department of Natural Resources (WDNR) Indoor Air Vapor Levels and Vapor Risk Screening Levels based on the May 2016 EPA Regional Screening Level Tables

Soil gas samples were collected using 1-liter, stainless-steel, cylindrical Summa® canisters. The sampling containers were provided by Pace Analytical (Pace), which subjected each canister to a rigorous cleaning process using a combination of dilution, heat, and high vacuum. After cleaning, the canisters were batch certified to be free of target contaminants to a specified reporting limit via gas chromatography/mass spectroscopy prior to delivery. Partner received the Summa® canisters evacuated to approximately 30 inches of mercury. The Summa® canisters were fitted with stainless-steel flow controllers, which ESC calibrated to maintain constant flow (approximately 200 milliliters per minute) for approximately five minutes of sampling time.

Each probe was allowed to equilibrate after installation prior to sampling. After equilibration, the sample tubing and sampler screen were purged of ambient air using a syringe and a PID reading was collected. Once the tubing was evacuated of ambient air, the sampling end of the tubing was fitted to the sampling canister and the port valve was opened, causing air to enter the sample container due to the pressure differential. Partner closed the valves after the canister was evacuated to approximately two inches of

mercury, with pertinent data (e.g., time, canister vacuum) recorded at the start and end of sampling. The Summa® canisters were labeled for identification and stored away from direct sunlight prior to analysis.

Refer to Figure 3 for a map indicating sub-slab sample location.

3.7 Post-Sampling Activities

Probes/temporary well points were removed from the subsurface and the boreholes were backfilled with hydrated bentonite chips following sampling activities. Following the removal of the Vapor Pin, the concrete slab and the hole created by the drill was backfilled with hydraulic concrete patch.

No significant amounts of derived wastes were generated during this investigation.

4.0 LABORATORY ANALYSIS

4.1 Laboratory Analysis

Partner collected ten soil samples, five groundwater samples, and three soil gas samples on October 3, 2018, which were transported in an iced cooler and/or shipping container (sub-slab) under proper chain-of-custody protocol Environmental Science Corporation Lab Sciences, Inc. (ESC), a state-certified laboratory [Wisconsin state accreditation certificate number 9980939910] in the City of Mount Juliet, Tennessee, for analysis on October 4, 2018.

Based on field-screening results, visual observations, and/or olfactory observations, two soil samples and one groundwater were collected from each boring. The deeper soil samples were analyzed for VOCs in accordance with EPA Method 8260 and PAHs single ion monitoring (SIM) in accordance with EPA Method 8270. The shallow soil samples were analyzed for Resource Conservation and Recovery Act (RCRA) 8 metals via EPA Methods 6010 and 7471. The groundwater samples were analyzed for VOCs in accordance with EPA Method 8260 and PAHs-SIM in accordance with EPA Method 8270.

The sub-slab soil gas samples were analyzed for VOCs in accordance with EPA Method TO-15.

4.2 Laboratory Analytical Results

Laboratory analytical results are included in Appendix B and discussed below.

4.2.1 Soil Sample Analytical Results

Several VOCs (including acetone, benzene, ethylbenzene, 2- butanone, naphthalene, toluene, 1,2,4-trimethylbenzene and 1,2,3-trimethylbenzene were detected at concentrations above the laboratory reported detection limit (RDLs) in one or more of the analyzed soil samples. No other VOCs were detected in the soil samples analyzed.

Between two and seventeen PAHs were detected at concentrations above the laboratory RDLs in soil samples B1(0.5-1), B3(3.-4) and B4 (6-7). PAHs were not present at detectable concentrations in the remaining soil samples analyzed. RCRA 8 metals including arsenic, barium, cadmium, chromium, lead, selenium and mercury were detected in the all soil samples analyzed for metals. Refer to Table 2 for a summary of the soil sample laboratory analysis results.

4.2.2 Groundwater Sample Analytical Results

One VOC constituent, p-isopropyltoluene, was detected at a concentration above the laboratory RDLs in the groundwater sample B1-GW. No other VOCs were detected in the remaining groundwater samples analyzed. Several PAHs were detected at concentrations above the laboratory RDLs in the groundwater samples B1-GW through B5-GW collected from borings B1 through B5 respectively.

Refer to Table 3 for a summary of the groundwater sample laboratory analysis results.

4.2.3 Sub-Slab Soil Gas Sample Analytical Results

Several VOCs including acetone, benzene, cyclohexane, ethanol, ethylbenzene, trichlorofluoromethane, dichlorodifluoromethane, heptane, n-hexane, methylene chloride, 2-butanone (MEK), 2-propanol,

propene, tetrachloroethene (PCE), toluene, trichloroethene (TCE), 1,2,4–trimethylbenzene, 1,3,5-trimethylbenzene, m & p xylene and o-xylene were detected above the laboratory sample detection limit in at least one or more of the sub-slab soil gas samples analyzed. No other VOCs were identified above the laboratory detection limts in the analyzed soil gas samples.

Refer to Table 4 for a summary of the sub-slab soil gas sample VOCs laboratory analysis results.

5.0 DISCUSSION AND CONCLUSIONS

5.1 Regulatory Agency Guidance

Soil Guidance

The analytical results of soil samples collected during this subsurface investigation were compared to calculate Site-Specific Residual Contaminant Levels (SSRCLs) using the EPA Regional Soil Screening Level Web Calculator and the WDNR Remediation & Redevelopment (RR) Program's guidance document entitled *Soil Residual Contaminant Level Determinations Using the U.S. EPA Regional Screening Level Web Calculator*, PUB-RR-890 issued January 23, 2014. Partner utilized the most recently updated WDNR RR program spreadsheet (June 2016) to obtain the Residual Contaminant Levels (RCLs) based on either the direct contact pathway (for sample results collected from zero to four feet bgs) and the soil to groundwater pathway (for sample results collected deeper than four feet bgs) for non-industrial property use as set forth in the *Department of Natural Resources Chapter NR 720 (NR 720) of the Wisconsin Administrative Code* (Wis. Adm. Code).

Groundwater Guidance

The groundwater sample analytical results were compared to groundwater contaminant concentrations as set forth in Department of Natural Resources Chapter NR 140, Wis. Admin. Code (NR 140). For each regulated compound, two standards have been established: the Enforcement Standard (ES) and the Preventive Action Limit (PAL). In general, if the regulated contaminant concentration exceeds the PAL value, but is below the ES value, the WDNR may require additional investigation/continued monitoring. If the regulated contaminant concentration exceeds the ES value, the WDNR may require additional investigation, continued monitoring, and/or remediation.

Sub-Slab Soil Gas Guidance

The sub-slab soil gas sample analytical results were compared to WDNR Vapor Risk Screening Levels (VRSLs) which are based on EPA regional screening level tables, applying a $1x10^{-5}$ excess lifetime cancer risk, or hazard index (HI) of 1. Current land use at the subject property is residential; therefore, residential standards were used.

5.2 Discussion

Soil

Exceedances of targeted RCRA metals were detected in the surficial soil samples collected from borings B1 through B5. Specifically, arsenic was detected at concentrations 17.7 milligrams per kg (mg/kg), 0732 mg/kg, 3.07 mg/kg, 116 mg/kg and 7.56 mg/kg in l the surficial soil samples B1(0.5-1) through B5(0.5-1) respectively exceeding the direct contact pathway non- industrial RCLs and the groundwater pathway RCLs. Lead was detected at concentrations of 940 mg/kg, 209 mg/kg, 272 mg/kg and 205 mg/kg in soil sample B1(0.5-1), B3(0.5-1), B4(0.5-1) and B5(0.5-1) respectively exceeding the groundwater pathway RCL and/or the direct contact pathway non- industrial RCLs. Cadmium, selenium and mercury exceedances were also detected in the surficial soil samples B1(0.5-1), B4(0.5-1) and B5(0.5-1). The detected VOCs and

PAHs in the soil samples were all below their applicable RCLs. Soil results indicate surficial soil at the property has been impacted with metals.

Groundwater

The PAH constituents benzo(a)pyrene and chrysene were detected at concentrations of 0.225 micrograms per liter (µg/l) and 0.454 µg/l in in groundwater sample B3-GW, exceeding their corresponding WDNR ES and PALs. Benzo(b)fluoranthene and fluoranthene were detected at concentrations of 0.156 µg/l and 0.243 µg/l in groundwater sample B3-GW at concentrations exceeding their respective PALs. Benzo(a)pyrene benzo(b)fluoranthene, chrysene and fluoranthene were also detected at concentrations of 0.0766 µg/l, 0.116 µg/l, 0.118 µg/l and 0.203 µg/l in groundwater sample B5-GW at concentrations exceeding their respective PALs. The remaining detectable concentrations of VOCs and PAHs in the analyzed groundwater samples did not exceed their respective RCLs.

The detected PAH exceedances in the groundwater samples warrants additional investigation/continued monitoring. Specifically, the elevated concentration may be attributable to the turbidity of the samples.

Soil Gas

Of the detected concentrations of VOCs in the analyzed soil gas samples, dichlorodifluoromethane was detected at concentrations of 7,060 micrograms per cubic meter (µg/m^3), 12,6000 µg/m^3 and 7,9000 µg/m^3 in VP-1, VP-2 and VP-3 respectively exceeding the applicable WDNR soil gas VRSL. The compound is a known Freon gas and may be associated with leaks from the on-site air conditioning system. Given the lack of significant concentrations of other VOCs, the dichlorodifluoromethane detections and exceedances do not appear related to the REC. However, further investigation would be required to verify the source.

5.3 Summary and Conclusions

Partner conducted a Phase II Subsurface Investigation at the subject property to evaluate the potential impact of VOCs, PAHs, and/or metals to soil, groundwater and or/soil gas as a consequence of a release or releases from the general historical former industrial use of the subject property and/or adjacent CREC sites.

The scope of the Phase II Subsurface Investigation included a geophysical survey to clear boring locations and the advancement of five borings (B1 through B5) within the subject property for the collection of investigative soil and groundwater samples. Additionally, three temporary sub-slab soil gas points (VP-1 through VP-5) was installed within the subject property.

Based on borings advanced during this investigation, no visual or olfactory evidence of impacted conditions were detected from the soil profile screened in any of the borings. No elevated PID readings were recorded on the soil profile screened from borings B1 through B5.

Based on field-screening results, visual observations, and/or olfactory observations, ten soil samples and five groundwater samples were collected from borings B1 through B5. Two soil samples (surficial and deeper) and one groundwater sample were collected from each boring. Three sub-slab soil gas samples VP-1 through VP-3 were also collected from the property

The soil samples were analyzed for VOCs in accordance with EPA Method 8260, PAHs single ion monitoring (SIM) in accordance with EPA Method 8270, and/or Resource Conservation and Recovery Act (RCRA) 8 metals via EPA Methods 6010 and 7471. The groundwater samples were analyzed for VOCs in accordance with EPA Method 8260 and PAHs-SIM in accordance with EPA Method 8270.

The sub-slab soil gas samples were analyzed for VOCs in accordance with EPA Method TO-15.

The analytical results of soil samples collected indicated exceedances of targeted RCRA metals including arsenic, cadmium, lead selenium and mercury in the surficial soil samples collected from borings B1 through B5. No VOCs and PAHs exceedances were detected in all the soil samples analyzed. Soil results indicate surficial soil at the property has been impacted with metals.

The analytical results of groundwater samples indicated that PAH constituents including benzo(b)fluoranthene, fluoranthene, benzo(a)pyrene and chrysene were detected in groundwater samples B3-GW and B5-GW at concentrations that exceed their corresponding WDNR ES and/or PALs. The detected PAH exceedances in the groundwater samples warrants additional investigation/continued monitoring. The elevated concentration may be attributable to the turbidity of the samples.

The analytical results of sub-slab soil gas sample indicate that of the detected concentrations of VOCs in the analyzed soil gas samples, only dichlorodifluoromethane exceeded the applicable WDNR soil gas VRSL. Given the lack of significant concentrations of other VOCs, the dichlorodifluoromethane detections and exceedances do not appear related to the REC. However, further investigation would be required to verify the source.

Based on the Phase II Subsurface Investigation, there is evidence of surficial soil metals impacts, possibly relating to the known USACE site. Partner recommends further investigation at the subject property.

Notes:
VOCs (8260)= Volatile organic compounds in accordance with United States Environmental Protection Agency (EPA) method 8260
PAHs (8270)= Polycyclic aromatic hydrocarbons in accordance with United States Environmental Protection Agency (EPA) method 8270
VOCs (TO-15)= Volatile organic compounds in accordance with United States Environmental Protection Agency (EPA) method TO-15
RCRA = Resource Conservation and Recovery Act in accordance with EPA methods 6010 and 7471
SIM = Single ion monitoring
bgs = Below ground surface

Notes:
WDNR = Wisconsin Department of Natural Resources
RCL = Residual Contaminant Level
bgs = below ground surface
SIM = selective ion monitoring
mg/kg = milligrams per kilogram
J = The identification of the analyte is acceptable; the reported value is an estimate
RDL = laboratory Reported Detection Limit
< = not detected above indicated RDL
NE = not established
NA = not analyzed
Values indicate a criteria exceedance

All sample aliquots were received at the correct temperature, in the proper containers, with the appropriate preservatives, and within method specified holding times, unless qualified or notated within the report. Where applicable, all MDL (LOD) and RDL (LOQ) values reported for environmental samples have been corrected for the dilution factor used in the analysis. All Method and Batch Quality Control are within established criteria except where addressed in this case narrative, a non-conformance form or properly qualified within the sample results. By my digital signature below, I affirm to the best of my knowledge, all problems/anomalies observed by the laboratory as having the potential to affect the quality of the data have been identified by the laboratory, and no information or data have been knowingly withheld that would affect the quality of the data.

Guide to Reading and Understanding Your Laboratory Report

The information below is designed to better explain the various terms used in your report of analytical results from the Laboratory. This is not intended as a comprehensive explanation, and if you have additional questions please contact your project representative.

Abbreviations and Definitions

(dry)	Results are reported based on the dry weight of the sample. [this will only be present on a dry report basis for soils].
MDL	Method Detection Limit.
MDL (dry)	Method Detection Limit.
ND	Not detected at the Reporting Limit (or MDL where applicable).
RDL	Reported Detection Limit.
RDL (dry)	Reported Detection Limit.
Rec.	Recovery.
RPD	Relative Percent Difference.
SDG	Sample Delivery Group.
(S)	Surrogate (Surrogate Standard) - Analytes added to every blank, sample, Laboratory Control Sample/Duplicate and Matrix Spike/Duplicate; used to evaluate analytical efficiency by measuring recovery. Surrogates are not expected to be detected in all environmental media.
U	Not detected at the Reporting Limit (or MDL where applicable).
Analyte	The name of the particular compound or analysis performed. Some Analyses and Methods will have multiple analytes reported.
Dilution	If the sample matrix contains an interfering material, the sample preparation volume or weight values differ from the standard, or if concentrations of analytes in the sample are higher than the highest limit of concentration that the laboratory can accurately report, the sample may be diluted for analysis. If a value different than 1 is used in this field, the result reported has already been corrected for this factor.
Limits	These are the target % recovery ranges or % difference value that the laboratory has historically determined as normal for the method and analyte being reported. Successful QC Sample analysis will target all analytes recovered or duplicated within these ranges.
Original Sample	The non-spiked sample in the prep batch used to determine the Relative Percent Difference (RPD) from a quality control sample. The Original Sample may not be included within the reported SDG.
Qualifier	This column provides a letter and/or number designation that corresponds to additional information concerning the result reported. If a Qualifier is present, a definition per Qualifier is provided within the Glossary and Definitions page and potentially a discussion of possible implications of the Qualifier in the Case Narrative if applicable.
Result	The actual analytical final result (corrected for any sample specific characteristics) reported for your sample. If there was no measurable result returned for a specific analyte, the result in this column may state “ND” (Not Detected) or “BDL” (Below Detectable Levels). The information in the results column should always be accompanied by either an MDL (Method Detection Limit) or RDL (Reporting Detection Limit) that defines the lowest value that the laboratory could detect or report for this analyte.
Case Narrative (Cn)	A brief discussion about the included sample results, including a discussion of any non-conformances to protocol observed either at sample receipt by the laboratory from the field or during the analytical process. If present, there will be a section in the Case Narrative to discuss the meaning of any data qualifiers used in the report.
Quality Control Summary (Qc)	This section of the report includes the results of the laboratory quality control analyses required by procedure or analytical methods to assist in evaluating the validity of the results reported for your samples. These analyses are not being performed on your samples typically, but on laboratory generated material.
Sample Chain of Custody (Sc)	This is the document created in the field when your samples were initially collected. This is used to verify the time and date of collection, the person collecting the samples, and the analyses that the laboratory is requested to perform. This chain of custody also documents all persons (excluding commercial shippers) that have had control or possession of the samples from the time of collection until delivery to the laboratory for analysis.
Sample Results (Sr)	This section of your report will provide the results of all testing performed on your samples. These results are provided by sample ID and are separated by the analyses performed on each sample. The header line of each analysis section for each sample will provide the name and method number for the analysis reported.
Sample Summary (Ss)	This section of the Analytical Report defines the specific analyses performed for each sample ID, including the dates and times of preparation and/or analysis.

Qualifier	Description
J	The identification of the analyte is acceptable; the reported value is an estimate.
J5	The sample matrix interfered with the ability to make any accurate determination; spike value is high.

Pace National is the only environmental laboratory accredited/certified to support your work nationwide from one location. One phone call, one point of contact, one laboratory. No other lab is as accessible or prepared to handle your needs throughout the country. Our capacity and capability from our single location laboratory is comparable to the collective totals of the network laboratories in our industry. The most significant benefit to our one location design is the design of our laboratory campus. The model is conducive to accelerated productivity, decreasing turn-around time, and preventing cross contamination, thus protecting sample integrity. Our focus on premium quality and prompt service allows us to be YOUR LAB OF CHOICE.
* Not all certifications held by the laboratory are applicable to the results reported in the attached report.
* Accreditation is only applicable to the test methods specified on each scope of accreditation held by Pace National.

ANALYTICAL REPORT

October 11, 2018

Partner Engineering & Science - IL

Sample Delivery Group:	L1031804
Samples Received:	10/04/2018
Project Number:	18-215232.3
Description:	Fox Shores Apartments
Site:	400 FOX SHORES DR. KAUKAUNA,WS
Report To:	Lucas Martin 805 North Milwaukee Avenue Suite 401 C Chicago, IL 60642

Entire Report Reviewed By: John V Hawkins

John Hawkins
Project Manager

Results relate only to the items tested or calibrated and are reported as rounded values. This test report shall not be reproduced, except in full, without written approval of the laboratory. Where applicable, sampling conducted by Pace National is performed per guidance provided in laboratory standard operating procedures: 060302, 060303, and 060304.

All sample aliquots were received at the correct temperature, in the proper containers, with the appropriate preservatives, and within method specified holding times, unless qualified or notated within the report. Where applicable, all MDL (LOD) and RDL (LOQ) values reported for environmental samples have been corrected for the dilution factor used in the analysis. All Method and Batch Quality Control are within established criteria except where addressed in this case narrative, a non-conformance form or properly qualified within the sample results. By my digital signature below, I affirm to the best of my knowledge, all problems/anomalies observed by the laboratory as having the potential to affect the quality of the data have been identified by the laboratory, and no information or data have been knowingly withheld that would affect the quality of the data.

Guide to Reading and Understanding Your Laboratory Report

The information below is designed to better explain the various terms used in your report of analytical results from the Laboratory. This is not intended as a comprehensive explanation, and if you have additional questions please contact your project representative.

Abbreviations and Definitions

MDL	Method Detection Limit.
RDL	Reported Detection Limit.
Rec.	Recovery.
RPD	Relative Percent Difference.
SDG	Sample Delivery Group.
(S)	Surrogate (Surrogate Standard) - Analytes added to every blank, sample, Laboratory Control Sample/Duplicate and Matrix Spike/Duplicate; used to evaluate analytical efficiency by measuring recovery. Surrogates are not expected to be detected in all environmental media.
U	Not detected at the Reporting Limit (or MDL where applicable).
Analyte	The name of the particular compound or analysis performed. Some Analyses and Methods will have multiple analytes reported.
Dilution	If the sample matrix contains an interfering material, the sample preparation volume or weight values differ from the standard, or if concentrations of analytes in the sample are higher than the highest limit of concentration that the laboratory can accurately report, the sample may be diluted for analysis. If a value different than 1 is used in this field, the result reported has already been corrected for this factor.
Limits	These are the target % recovery ranges or % difference value that the laboratory has historically determined as normal for the method and analyte being reported. Successful QC Sample analysis will target all analytes recovered or duplicated within these ranges.
Qualifier	This column provides a letter and/or number designation that corresponds to additional information concerning the result reported. If a Qualifier is present, a definition per Qualifier is provided within the Glossary and Definitions page and potentially a discussion of possible implications of the Qualifier in the Case Narrative if applicable.
Result	The actual analytical final result (corrected for any sample specific characteristics) reported for your sample. If there was no measurable result returned for a specific analyte, the result in this column may state “ND” (Not Detected) or “BDL” (Below Detectable Levels). The information in the results column should always be accompanied by either an MDL (Method Detection Limit) or RDL (Reporting Detection Limit) that defines the lowest value that the laboratory could detect or report for this analyte.
Case Narrative (Cn)	A brief discussion about the included sample results, including a discussion of any non-conformances to protocol observed either at sample receipt by the laboratory from the field or during the analytical process. If present, there will be a section in the Case Narrative to discuss the meaning of any data qualifiers used in the report.
Quality Control Summary (Qc)	This section of the report includes the results of the laboratory quality control analyses required by procedure or analytical methods to assist in evaluating the validity of the results reported for your samples. These analyses are not being performed on your samples typically, but on laboratory generated material.
Sample Chain of Custody (Sc)	This is the document created in the field when your samples were initially collected. This is used to verify the time and date of collection, the person collecting the samples, and the analyses that the laboratory is requested to perform. This chain of custody also documents all persons (excluding commercial shippers) that have had control or possession of the samples from the time of collection until delivery to the laboratory for analysis.
Sample Results (Sr)	This section of your report will provide the results of all testing performed on your samples. These results are provided by sample ID and are separated by the analyses performed on each sample. The header line of each analysis section for each sample will provide the name and method number for the analysis reported.
Sample Summary (Ss)	This section of the Analytical Report defines the specific analyses performed for each sample ID, including the dates and times of preparation and/or analysis.

Qualifier	Description
B	The same analyte is found in the associated blank.
J	The identification of the analyte is acceptable; the reported value is an estimate.
J3	The associated batch QC was outside the established quality control range for precision.
J4	The associated batch QC was outside the established quality control range for accuracy.

Pace National is the only environmental laboratory accredited/certified to support your work nationwide from one location. One phone call, one point of contact, one laboratory. No other lab is as accessible or prepared to handle your needs throughout the country. Our capacity and capability from our single location laboratory is comparable to the collective totals of the network laboratories in our industry. The most significant benefit to our one location design is the design of our laboratory campus. The model is conducive to accelerated productivity, decreasing turn-around time, and preventing cross contamination, thus protecting sample integrity. Our focus on premium quality and prompt service allows us to be YOUR LAB OF CHOICE.
* Not all certifications held by the laboratory are applicable to the results reported in the attached report.
* Accreditation is only applicable to the test methods specified on each scope of accreditation held by Pace National.

All sample aliquots were received at the correct temperature, in the proper containers, with the appropriate preservatives, and within method specified holding times, unless qualified or notated within the report. Where applicable, all MDL (LOD) and RDL (LOQ) values reported for environmental samples have been corrected for the dilution factor used in the analysis. All Method and Batch Quality Control are within established criteria except where addressed in this case narrative, a non-conformance form or properly qualified within the sample results. By my digital signature below, I affirm to the best of my knowledge, all problems/anomalies observed by the laboratory as having the potential to affect the quality of the data have been identified by the laboratory, and no information or data have been knowingly withheld that would affect the quality of the data.

John Hawkins

Guide to Reading and Understanding Your Laboratory Report

The information below is designed to better explain the various terms used in your report of analytical results from the Laboratory. This is not intended as a comprehensive explanation, and if you have additional questions please contact your project representative.

Abbreviations and Definitions

MDL	Method Detection Limit.
ND	Not detected at the Reporting Limit (or MDL where applicable).
RDL	Reported Detection Limit.
Rec.	Recovery.
RPD	Relative Percent Difference.
SDG	Sample Delivery Group.
(S)	Surrogate (Surrogate Standard) - Analytes added to every blank, sample, Laboratory Control Sample/Duplicate and Matrix Spike/Duplicate; used to evaluate analytical efficiency by measuring recovery. Surrogates are not expected to be detected in all environmental media.
U	Not detected at the Reporting Limit (or MDL where applicable).
Analyte	The name of the particular compound or analysis performed. Some Analyses and Methods will have multiple analytes reported.
Dilution	If the sample matrix contains an interfering material, the sample preparation volume or weight values differ from the standard, or if concentrations of analytes in the sample are higher than the highest limit of concentration that the laboratory can accurately report, the sample may be diluted for analysis. If a value different than 1 is used in this field, the result reported has already been corrected for this factor.
Limits	These are the target % recovery ranges or % difference value that the laboratory has historically determined as normal for the method and analyte being reported. Successful QC Sample analysis will target all analytes recovered or duplicated within these ranges.
Qualifier	This column provides a letter and/or number designation that corresponds to additional information concerning the result reported. If a Qualifier is present, a definition per Qualifier is provided within the Glossary and Definitions page and potentially a discussion of possible implications of the Qualifier in the Case Narrative if applicable.
Result	The actual analytical final result (corrected for any sample specific characteristics) reported for your sample. If there was no measurable result returned for a specific analyte, the result in this column may state “ND” (Not Detected) or “BDL” (Below Detectable Levels). The information in the results column should always be accompanied by either an MDL (Method Detection Limit) or RDL (Reporting Detection Limit) that defines the lowest value that the laboratory could detect or report for this analyte.
Case Narrative (Cn)	A brief discussion about the included sample results, including a discussion of any non-conformances to protocol observed either at sample receipt by the laboratory from the field or during the analytical process. If present, there will be a section in the Case Narrative to discuss the meaning of any data qualifiers used in the report.
Quality Control Summary (Qc)	This section of the report includes the results of the laboratory quality control analyses required by procedure or analytical methods to assist in evaluating the validity of the results reported for your samples. These analyses are not being performed on your samples typically, but on laboratory generated material.
Sample Chain of Custody (Sc)	This is the document created in the field when your samples were initially collected. This is used to verify the time and date of collection, the person collecting the samples, and the analyses that the laboratory is requested to perform. This chain of custody also documents all persons (excluding commercial shippers) that have had control or possession of the samples from the time of collection until delivery to the laboratory for analysis.
Sample Results (Sr)	This section of your report will provide the results of all testing performed on your samples. These results are provided by sample ID and are separated by the analyses performed on each sample. The header line of each analysis section for each sample will provide the name and method number for the analysis reported.
Sample Summary (Ss)	This section of the Analytical Report defines the specific analyses performed for each sample ID, including the dates and times of preparation and/or analysis.

Qualifier	Description
J	The identification of the analyte is acceptable; the reported value is an estimate.

Pace National is the only environmental laboratory accredited/certified to support your work nationwide from one location. One phone call, one point of contact, one laboratory. No other lab is as accessible or prepared to handle your needs throughout the country. Our capacity and capability from our single location laboratory is comparable to the collective totals of the network laboratories in our industry. The most significant benefit to our one location design is the design of our laboratory campus. The model is conducive to accelerated productivity, decreasing turn-around time, and preventing cross contamination, thus protecting sample integrity. Our focus on premium quality and prompt service allows us to be YOUR LAB OF CHOICE.
* Not all certifications held by the laboratory are applicable to the results reported in the attached report.
* Accreditation is only applicable to the test methods specified on each scope of accreditation held by Pace National.

8 Unit Apartment / Condominium Building

JACOBSON, PROMER & PROMER

Kaukauna, Wisconsin

GENERAL NOTES

- The buildings are designed to conform to Wisconsin D.I.L.H.R. Chapter Ind. 57, Type #8, wood frame unprotected construction as eight family apartment/condominium buildings. All work shall conform to state and local codes which govern for the building site. Any additions to or deletions from the plan shall be in accordance with state and local codes and may require resubmittal. Notify the Architect of such changes.
- The Division of Work, and Contract requirements shall be as negotiated with the Owner. Project schedule and expedition of work shall be as directed by the Owner or his representative.

SITE WORK - GENERAL NOTES & SPECIFICATIONS

- The project will be to construct two(2) Eight-family apartment buildings. One for each of two owners and one each future.
- The sites are Lots #1 and #2 of a certified survey map pending approval. The Lots are part of parcel #3 of Outagamie County Certified Survey Map #59, City of Kaukauna, Outagamie County, Wisconsin.
- Location of utilities where shown on the drawings are based on available records and are not guaranteed to be complete or correct The intention is to assist the contractor in making determination of exact location.
- The buildings on the site shall be staked out and footing elevations set by the concrete contractor and shall be approved by the Architect/Owner before excavation is begun.
- Soil borings, samples, and testing was not done. Soil bearing capactiy is assumed at 3000 PSF sandy clay silt per Ind. 53.12, Table 53-II. The contractor shall notify the Architect immediately if soils other than those indicated are encountered.
- The electrical, telephone, gas and cable television services shall be by the utilities company's supplying service.

2A. EXCAVATION

- This contractor shall strip the site of top soil if any and stockpile for finish grading.
- Excavate to grade lines, for footing, & basement floor slab as shown on the drawings. Stockpile at site material needed for back filling, & rough grading. Footings shall bear on undisturbed soil. Backfill with 6" compacted gravel under slabs and excavated earth on exterior, compact uniformly. Excess excavated material shall be hauled to a site as directed by Owner within 2 mile radius. Coordinate badkfilling with concrete contractor for placement of perimeter insulation.
- The site was formerly a railroad yard. The approximate location of former buildings is shown on the site plan. It is believed that building foundations and slabs remain buried at the site. The Excavation contractor in preparing his bid shall determine to his own satisfaction the extent and type of materials to be excavated.
- After backfillings, rough grade site to obtain gradual slope from building to property lines, drives, walks etc. and spread top soil if any, over areas to be lawn.
- Cutting, & grading of the parking area shall be by the asphalt contractor. Trenching for utilites shall be by the utility contractor.

2B. ASPHALT PAVING

- Asphalt contractor is to excavate and haul away materials for the parking area and drive where shown on the drawings. Provide 8" compacted subbase material of crushed limestone. Provide asphalt concrete paving of 2" thickness. This contractor is to layout work, to provide drainage to the catch basin shown. This contractor is to meet with the utilitiy contactor, architect, and concrete contractor to determine and set grade and elevations if required. Include parking striping as shown on the site plan.

2C. UTILITES

- This contractor is to furnish labor and material to install the sanitary laterals, water service, catch basin, & storm sewer system as shown on the site plan. This contractor is to include in his bid all licenses, permits, and fees necessary to perform work ready for final connection to building by others.
- All work shall conform to state and local codes, and shall meet the requirements of the utility and/or municipality providing the service.
- All materials shall be approved and new. The water service shall be type "K" copper. The sanitary & storm laterals shall be Schedule 30 ABS or PVC. The catch basin shall be 36" diameter by 4'-0" deep, concrete pipe. The rim and grate shall be Neenah Foundry #R-2501; or equal.

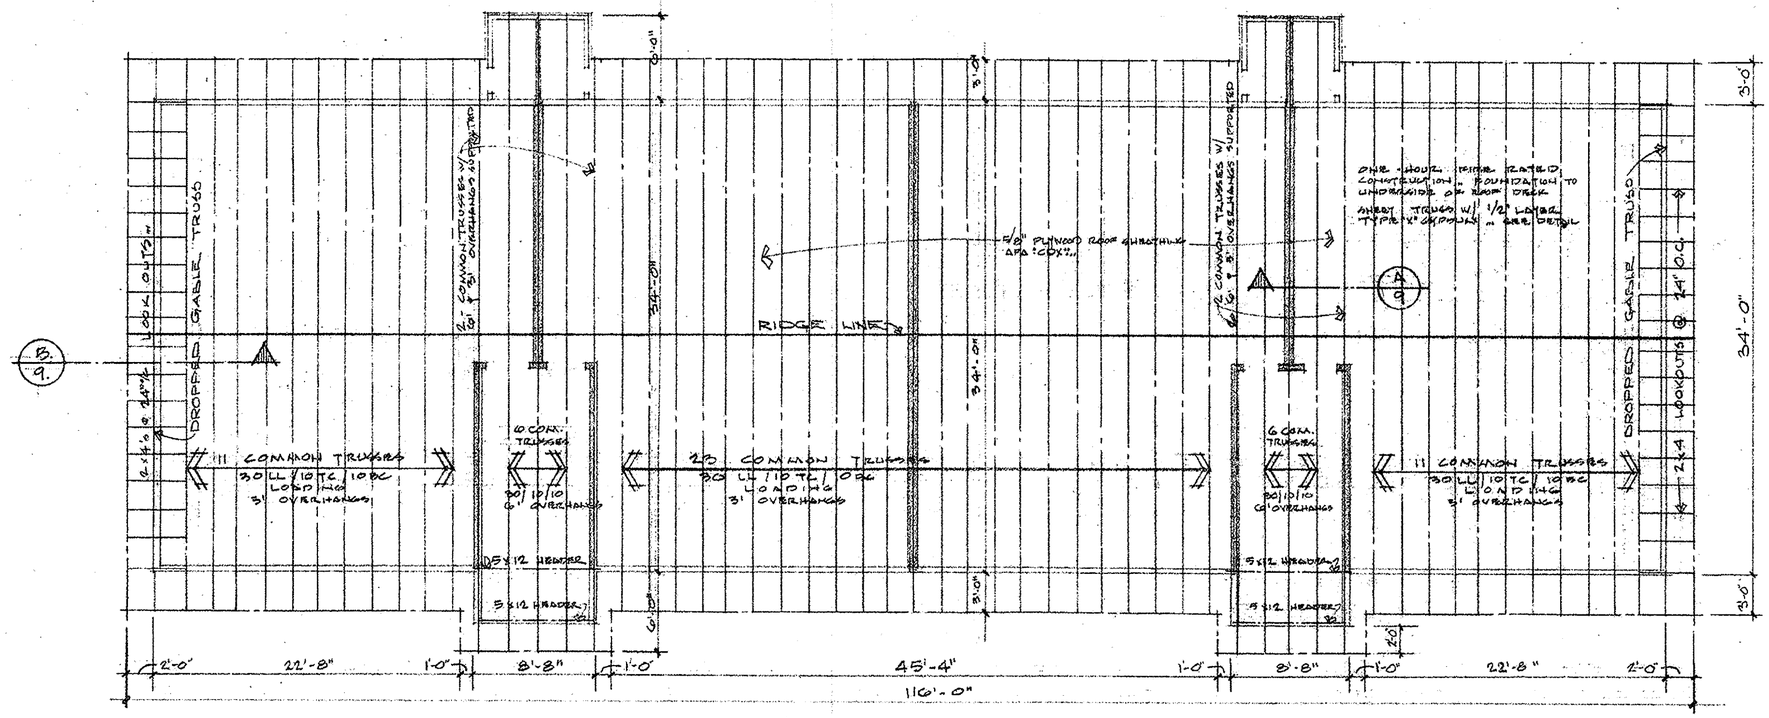
& SPECIFICATIONS - Continued from Sheet 11.

PECIALTIES

Provide a shower rod, bathroom towel bar (30") and paper holder in polished chrome finish.
Fire extinguishers shall be "Kidde" model #6TPS: 2A-40BC, 6lb./gal. extinguishers, or approved equal. Provide unit with surface wall mount.
Smoke detectors shall be provided where shown on the electrical plan sheets E-2. Detectors shall be ionization unit, with test button, solid state, white polymer housing, powered by 9-volt alkaline battery, similar to First-Alert, Sears, or equal. (12 req'd. thus).
Wrought iron railings shall be similar to "Logan Co." commerical railing, meeting Wisconsin D.I.L.H.R. code requirements. Railings shall be 42: high, with balusters at 9" and o/c, and able to support a 200 lb. load at any point. Provide all accessories required for complete installation; furnish prefinished in flat black. Submit shop drawings to the office of the Architect for approval.
Appliances by Owner: Ranges (8), Refrigerators (8), Ductless Rangehoods (8), Washers (2), and Dryers (2).

EATING, VENTILATING, and AIR CONDITIONING



Heating, Ventilating, and Air Conditioning work shall be as shown on the H & V plans sheet HV 1 & 2.

LUMBING

Plumbing work shall consist of a complete and operable plumbing system as shown on Plumbing plans, P-1 & P-2. Utility site work shown on sheet 2 shall be a separate contract. Submit bid separately.

ECTRICAL

lectrical work shall be as specified and shown on the Electrical plans sheet E-1, & E-2, & E-3.

SHEET 10 OF 18

N23693

GENERAL NOTES & SPECIFICATIONS

1. GENERAL CONDITIONS

- o The Contractors are to furnish materials and labor to execute the work as shown on the drawings. Division of work shall be by separate contracts as requested by the Owner, or his representative.
- o All work shall be in compliance with all codes and laws which govern for location of the building site.
- o Reference to materials or systems herein by name, make or catalog number is intended to establish a standard of quality, and not to limit competition; and the words "or approved equal" are implied following each brand name.
- o Workmanship shall be of the best quality. Inasmuch as the specifications hereinafter are of a brief nature, it is the intent that each contractor provide workmanship that is neat, secure, with the best possible appearance and utility. The Architect will be judge of installed work, and may reject work which does not meet the standards established hereby. Such rejected work shall be repaired or replaced to the satisfaction of the Architect, without cost to the Owner.
- o All Contractors are responsible for the removal of their own refuse from the premises. Final cleaning and washing of glass is by the Owner.
- o Temporary electrical power will be provided by the owner, under the electrical contract.
- o The coordination and scheduling of work shall be by the Owner or the Owner's Expeditor/Representative.

2. SITE WORK

- o Site work shall be as described on sheet 2.

3. CONCRETE

- o Concrete work shall include wall and column footing, foundation walls, floor slabs, stoops, private walks, and aprons as shown on the drawings. This contractor shall stake out the buildings on the site and determine footings elevations.
- o All concrete shall be ready-mixed furnished by a reputable vendor in accordance with ASTM C94. Concrete shall be 3000 psi compressive strength at 28 days; maximum aggregate size 3/4" in all concrete; maximum water/ cement ration 5:1, minimum of 6 bags of cement per cu. yd.; 6% air entrainment (+ 1%), and water shall be potable. Maximum slump for walls shall be three inches; others four inches.
- o Contractor shall be responsible for adequacy of design and construction of forms, centering, shoring, and bracing. As a minimum, the Contractor shall follow ACI Standard Recommended Practice for Concrete Formwork (ACI 347-63). Supports for forms and centering shall be sufficiently strong to carry both dead and live loads to which they will be subjected. Shoring and supports shall be adjustable to permit tightening, bracing, leveling, and cambering as required.
- o Reinforcing steel shall conform to ASTM A615-40 fy = 40000 PSI. Reinforcing shall be suitably branded with rolled - in marks to visually establish the grade and size. Welded wire fabric reinforcement shall be electric welded, steel wire fabric conforming to ASTM A285, 6"x6" - #10/10. All reinforcing material shall be uncoated, unpainted, free from rust, scale, and dirt; and shall be placed in conformance with CRSI "Recommended Practice for Placing Bars", latest edition.
- o When the mean daily temperature of the atmosphere is less than 40°F., the temperature of the concrete shall be maintained between 50 and 70°F. for the required curing period. When necessary, arragnements for heating, covering, insulating, or housing the concrete work shall be made in advance of placement and shall be adequate to maintain the required temperature and moisture conditions without injury due to concentration of heat. Cold weather requirements shall comply with ACT-306-66.
- o Slabs shall be placed on 4 mil (.004") polyethylene plastic film. Lap joints 6" minimum. Smooth dense steel trowel finish on all interior slabs. Skip resistant broom finish on walks and stoops.
- o This contractor is to provide and install the perimemter insulation shown on the drawings. Coordinate this work with the backfilling by the excavation contractor. Perimeter insulation shall be beaded styrofoam of R=5.9; or equal extending 4' vertical. Let vertical members dry prior to backfilling: butt joints snug. Keep area between concrete and insulation free of backfill and other debris.
- o Precast concrete patio slabs and stair treads shall be as manufactured and designed by a State approved firm normally engaged in precast concrete design and manufacture. Units shall be designed to carry a superimposed loading of 100 PSF. Provide all anchors and miscellaneous hardware as shown for erection. Any State of Wisconsin D.I.L.H.R. component approval shall be by the supplier.
- o The lighweight concrete underlayment shall be as manufactured by Gyp-crete, Elastizell, or equal. This contractor shall furnish all labor and materials for installation as shown on the drawings. Application shall be by an approved applicator according to the manufacturer's printed specifications. Plywood subflooring shall be primed, and underlayment layer a minimum of 1½" thick.

4. MASONRY

- o The masonry contractor shall furnish labor and materials for the brick veneer work shown on the floor plans and building elevations.
- o Brick veneer masonry units shall be ASTM-C652 hollow clay units of modular size and laid in running bond with 3/8" joint. Color and final selection of the brick shall be made by the Architect/ Owner. Allow $280. per thousands in preparing bid.
- O Mortar shall be Type N, 1,1,6 mix of reputable vendor with ASTM C144 sand and potable water.
  Mortar color shall be added according to the requirements of BIA. Color as selected by the Architect/Owner.
  No air entraining admixtures or anti-freeze compounds may be added to the mortar.
- o Cold weather construction shall be according to B.I.A. recommendation. A copy of which is available from the office of the Architect. Provide veneer ties of 22 gage galvanized metal at 16" o/c each way; 6" long and 7/8" wide.
- o Lay brick plumb and true to lines. Lay with completely filled mortar joints. Tool joints concave. Provide weep holes in head joints in first course immediately above all flashing by placing and leaving a sash cord in joint.
- o Masonry shall be left clean, free of stains, and acceptable by the Architect and Owner. Do no use cleaning agents other than water without approval of the Architect.
- o Veneer lintels shall be ASTM A-36 angle, shop primed - L3½"x4x¼".

5. METALS

- o Metal work shall include providing and installing the miscellaneous structural steel as shown on the drawings.
- o Structural steel framing shall be of ASTM A-36 steel. Shop prime one coat of manufacturers standard rust inhibitiing primer. Provide holes, anchor bolts, bearing plates, as required for complete job. Verify exact length of beam and columns at the job site.
- o All steel work shall conform to the American Institute of Steel Construction, Code of Standard Practice.

6. CARPENTRY

- o The carpentry contract shall include all work under this division, and also supplying material and labor to install work under, Division 7 except insulation; Division 8 doors; windows and hardware; and Division 10, specialties.
- o Roof truss design and State of Wisconsin D.I.L.H.R. approval shall be the responsibility of the supplier prior to fabrication. Design for a superimposed roof load of 50 PSF. Provide shop drawings and State approved drawings.
- o Rough framing materials shall be as follows: 2x4's and 2x6's Southern Yellow Pine, or White Fir, No. 2 construction grade or better; 2x10's joint framing Douglas fir-larch #2 construction grade or better; with a moisture content not to exceed 20% and shall be kiln dried. Each piece of lumber shall bear the grade and trademark of its producer. Structural and framing lumber shall be S4S unless noted otherwise.
- o Plywood roof and wall sheathing shall be of size shown on the drawings of standard INT-APA grade "CDX" (with exterior glue) fir with ply clips if required. Plywood sheathing at all corners of ½"x½" thermax over balance of walls 1" insulating sheathing thermax foil backed, R=8.
- o Sub-flooring shall be 5/8" INT-APA grade "CDX" plywood (with exterior glue).
- o Siding shall be Prefinished Hardboard Panel Siding (PS 60 Standard) as selected by the Owner/Architect. Material shall be a minimum 7/16" thick, channel grooved (grooves 4" to 8" o.c., wood textured hardboard, 48"x96". Fasteners shall be 10d Aluminum or hot-dipped zinc-coated siding or box nails to color match materials. Install per manufacturer's printed specifications. Install so that all edges are backed by solid lumber framing or blocking, nailing at 6" intervals at panel perimeter and 12" at intermediate supports; leave 1/16" space between adjacent panels. Caulk butt joints at inside and outside corners and at trim locations; install continous color matched galvanized or aluminum "Z" flashing at horizontal panel joints.
- o Framing lumber and other rough work shall be closely fitted, accurately set to required lines and levels, and rigidly secured in place. Studs shall be sized to give true surfaces receiving finish materials. Partitions shall be framed with 2x4 studs spaced 16" on centers, unless detailed otherwise. Plates of partitions resting on concrete floors shall be anchored in place with ½" bolts spaced not more than 6' apart. Studs shall be doubled at openings. Headers for openings shall be made of 2 pieces of material set on edge; depth to suit size of opening per applicable code. Corners shall be thoroughly spiked and made solid. End studs of partitions abutting concrete walls shall be securely anchored, using ½" bolts not over 4' on centers. Partitions shall be provided with blocking for trim, recessed cabinets, plumbing, and other work to be concealed. Nailing strips shall be cut-in as required for support of fixtures of all kinds.
- o Finish carpentry shall be select oak as shown on the drawings with a moisture content not less than 6% or more than 15%. In no instance shall any woodwork be stored or installed in any area unless the entire area is broom clean, closed in , and possessing a realtive humidity below 50% at 70°F. All species shall contain only minor inherent natural defects, except that defects covered by adjoining members, concealed when the stock is installed, or not visible after pigmented finishing (as stain) may be admitted. Lengths shall be in the proportion available in the species and grade specified. Trim members shall be "backed-out" when 1-5/8" wide or wider, and for application on flat surfaces. Exposed surfaces shall be machine sanded on top face surfaces only, machine run otherwise. Working defects, as torn grain, machine marks, cross sanding, tool marks, will not be permitted. Edges shall be milled straight and true, and then exposed corners shall be slightly rounded. Scribing and joining shall be done accurately and neatly, so as to produce concealed and permanently tight joints, in a uniform plane for best appearance. Unless detailed otherwise, corners shall be mitered, except the inside corners shall be scribed; horizontal running trim shall butt vertical standing trim. Joints in horizontal running trim shall be scarfed glued and nailed. Where nailing is exposed, use finishing nails, counter-sunk.
- o Miscellaneous fasteners and rough carpentry hardware where not called out on the drawings shall be of a size and spacing which will develop the full strength of the members being fastened.
- o Cabinets will be furnished by the Owner. Bid shall include installation and 3-cove plastic laminate countertops. Colors as selected by the Architect/ Owner.
- o This contractor shall provide closet shelving, rods, and stair handrails.

7A. THERMAL & MOISTURE PROTECTION - Insulation

- o Building wall insulation shall be standard fiberglass, 3½" full thick, friction fit and unfaced batt with an R=13 value as shown on the drawings. Cover with 4 mil. (.004") thick polyethylene film. Ceiling insulation shall be standard fiberglass blanket insulation with craft paper backing to be stapled between truss chords and 9" blown fiberglass cover to provide a total R=38. Apply friction fit batt insulation and blankets to fit snugly between framing members at corners, wall intersections etc., between framing members and window frames, door frames, air sleeves, mechanical piping etc., to provide a completely insulated with a 3½" and 6"x4'0 sound attenuation batt respectively as shown on the drawings -- see wall section A/9.

7B. THERMAL & MOISTURE PROTECTION - By Carpentry Contractor

- o Roofing shall be a 225 pound fiberglass shingle, Class "A" similar to Johns-Mansville "Fire-Glass III, Seal-O-Matic," or equal. Color as selected by the Architect/Owner. Submit samples for approval. Apply one layer of #15 felt underlayment over plywood sheathing, lapping 2" at horizontal and 6" at vertical joints. At eaves provide a double layer two feet into interior space. Secure to hold in place. Install Type "D" galvanized room edge and starter strip; project over edge of sheathing 3/8" to form a drip. Use fasteners of hot galvanized steel or aluminum (10½ to 12 gauge) roofing nails having heads of at least 3/8" in diameter. Use nails of sufficient length to penetrate sheathing. Seal perimeter edges of shingle with a roofing cement. Install shingles per manufacturers standard specifications for the shingles used.
- o Flashing and sheet metal shall be a 26 ga. galvanized iron of best commerical grade fabricated to the size and contour as shown on the drawings. Provide poly vinyl ethylene sheet flashing as noted on the drawings of 6 mil thickness.
- o Soffit, and fascia system shall be preformed aluminum similar to Rollex-3. Provide trim pieces and accessories for complete job. Color as selected by the Architect. Seamless gutters and downspouts shall be color matched of .032" and .024" aluminum respectively.

8. WINDOWS, DOORS, & HARDWARE

- o Materials specified herein are to be furnished by the carpentry contractor.
- o Windows are to be Kolbe & Kolbe Clad Casement as shown on the drawings #KCW24 & #KCX13 with pre-finished painted interior. Glaze with manufacturer's standard double pane insulating glass, provide insect screen and extension jambs for a (2x4) stud wall with ½" interior finish board and exterior sheathing.
- o Patio door units shall be Andersen Corporation Perma-Shield PSII 6; as shown on the drawings. Glaze with manufacturer's standard 5/8" safety insulating glass, provide insect screen and jamb extensions for 5" wall ½"x½" thermax over system.
- o Exterior doors shall be Pease "Every-Strait" models #E-1, 3'0"x6'-8". See Door Schedule, Sheet 4. Frames are to be wood. Door swings to be verified at the site by Architect before ordering. Jamb width to be 5". Provide brick moulding.
- oInterior apartment-room doors shall be 6'8"x1-3/8" width shown on the plans, hollow standard "K" core, with rotary-cut Lauan Mahogany veneers, AWI "Custom" Grade. Door jambs and casings shall be oak or oak veneer. Hardware shall be hinges, and passage or privacy locksets. (Door units may be pre-hung.)
- o Bi-fold closet doors shall be "The Louver II" full louver by Slimfold Manufacturing Company, Inc. or approved equal pre-finished 24 gauge steel folding doors. Doors shall be factory assembled and supplied with all mounting hardware. Prefinished enameled paint color shall be Navajo White.
- o Each carpentry contractor shall include in his proposal an allowance of $2,000. per building for hardware. The successful bidder shall submit a hardware schedule for approval.

9. FINISHES

- o Carpeting, sheet vinyl, and ceramic tile work shall be by the Owner.

9A. FINISHES - Gypsum Board

- o Gypsum wall board shall be ½", regular 4'-0"xlength as required. Fastener shall be power driven, type S bugle head, 1" long. Joint treatment shall be a dura bond compound and Pert-A-Type. Joint compound for embedding and topping compound for fill and finishing per gypsum board manufacturer specification.

9B. PAINTING

- o Painting and staining shall be by an established firm
- o The painting contractor shall furnish labor and materials to stain and varnish with a three coat system (stain, sealer, varnish) all exposed wood surfaces. In general, this includes doors, frames, windows, casings, handrails, baseboard, and shelving, (cabinets are prefinished). Verify with Owner other materials pre-finished and the extent of work regarding this section.
- o Paint all gypsum board surfaces, except ceilings with two coats (plus primer if required for good coverage) system of flat latex except kitchen and bathroom, which shall have final coat of semi-gloss latex. See room finish schedule. Exterior doors and frames shall be painted with two coats of exterior oil base flat enamel. Colors for all coats as selected by the architect/owner. Submit to his office a color chart from the proposed manufacturer's of materials to be used. Each container shall be labeled by manufacturer stating type of paint, color or paint, and instructions for reducing. Brush, roll, or spray on materials smoothly in solid, even colors without drops, runs, lumps, defective brushing, discoloration or clogging of lines and angles. Make edges of paint adjoining other materials or colors sharp and clean, without overlapping. Apply per manufacturer printed recommendations.

EQUIPMENT SPECIFICATIONS

Electric Baseboard

All electric baseboard heaters shall be of highest quality construction, UL rated, and be completely silent in operation. A built in wireway shall allow wiring two or more units together without additional accessories. Finish shall be neutral tan baked enamel on zinc coated heavy gauge steel. The safety cutout shall run the full length of the heating element. A typical 4' section rated at 187 watts per lineal foot must have a reflectance rating in excess of 73. Elements shall be constructed of aluminum sheath enclosing a long-life element wire encapsuled in magnesium oxide. The aluminum sheath is .600" in diameter. the aluminum fins over the sheath are 2 1/8" by 2 3/8" and there are 62 fins per active foot of element, giving a total heating surface of 316.09 square inches per foot insuring the lowest heating element temperature. Units shall have fully enclosed wireway that will accommodate 60°C or TW wire. The baseboard heater element shall be warranted against burnout in the building in which it is originally installed. The contractor shall meet the provisions of the warranty or shall be liabel for any burnout. Heaters shall be of voltage, size, density, and with accessories shown on drawings and shall be Series X as manufactured by Orbit Manufacturing, Perkasie, Pennsylvania, or approved equal.

Air Conditioner

All air conditioners shall be Power-Aire manufactured by Heat Controller Inc. of Jackson, Mich. The unit shall have a zinc clad steel cabinet with a slide out chassis, fresh air control, thermostat, 2 speed fan, and have adjustable air deflection. It shall be warranted to be free from defects in material and workmanship under normal use for a period of one year from date of installation. In addition, the refrigeration system, consisting of the compressor, evaporator, condenser, and factory connected tubing, shall be warranted for a period of 4 additional years following the standard one year warranty. The unit shall be of sizes and capacities shown on plan.

PLUMBING MATERIALS & SPECIFICATIONS

General

All materials shall conform to section H62.19 of the Wisconsin Administrative Code and shall be installed in accordance with the approved plans and in accordance with Chapter H62 of the Wisconsin Administrative Code. Fixtures for each apartment are to be color matched as chosen by the Owner or Architect.

Piping

All drain and vent piping shall be Schedule 40 ABS or PVC. Underground water distribution piping shall be Type "K" copper. Above ground water distribution shall be Type "L" copper. Waste and vent piping which penetrates the onephour party walls shall be metal or in a metal sleeve per code.

Tub/Shower

T-1 LASCO Industries "Model #2603-SG", fiberglass tub and shower module with Delta #636 shower/faucet, and Kohler #K-11660 TRIP WASTE, all in chrome finish; or equal.

Waterclosets

WC-1 Mansfield "Mohican #126-35", vitreous china, jet flush watersaving, regular bowl, colored, with solid plastic, colored seat w/cover; or equal.

Lavatories

L-1 Mansfield "Starlet 19" x 16" oval self-rimming, colored, vitreous china, with Delex #2522 faucet, chrome; or equal

Sinks

S-1 Dayton #D-23321-4, 33" x 21" stainless steel, 2-compartment sink, with Delex faucet #2402 w/spray for conditioned water, and Elkay faucet #LK-2085-13 gooseneck for drinking water; or equal.

Disposal

Shall be an Elkay #LKD 50, waste disposal, 1/2 hp., 120 volts, 1 phase, 7.2 amps; or equal.

Hose Bibbs

HB-1 Shall be freezeproof Woodford #14C with backflow preventers; or equal (Sillcock)

HB-2 Shall be laundry hose connections Nibco, Inc. #61; or equal.

Floor Drains

FD-1 Shall be Schier #N-104-3, 3" diameter pipe capacity; or equal.

FD-2 Shall be a 2" ABS or PVC with shower strainer.

WD-1 Shall be a 2" ABS or PVC wall drain for laundry washer drain, with open site top.

Clean Outs

Shall be 4" diameter Schier Model #106RS; or equal.

Water Conditioner / Softener

Shall be a Dickinson Model # MGT-210-1½ water conditioning unit with 21" diameter x 62" filter with 7 cubic feet capacity tank, with 1½" diameter Hayes Automatic Reset flow meter with time delay. Tank to be fiberglass.

Brine tank shall be 24" diameter x 54" high, 900 lb. salt storage capacity of polyethylene.

Water Heaters

Shall be Rheem "Rheemglas Standard" Model #668HS-30D, 30 gal. electric unit for 208 volt, single phase, with 2-4500 watt heating elements, one year limited warranty, 5-year warranty tank.

Water heaters shall be set in a 24" x 24" square x 2" high 24 gauge galvanized iron pan with ½" diameter copper outlet to drain.

Note: See site plan for additional site work under separate contract.

Work under this contract shall extend to the building line. Final connections to utilites shall be by this contractor.

ELECTRICAL NOTES & SPECIFICATIONS

- o All work shall be done in stricte accordance with all national, state and local codes. The Electrical contractor shall obtain and pay for all licenses, permits, and taxes necessary to perform work under this division.
- o The intent and object of these notes, plans, and specifications is for the Electrical contractor to include a complete, operable electrical system connecting all electrical devices and/or equipment furnished by other contractors. All 110 volt wiring by the electrical contractor. Low voltage wiring by others, with necessary conduit by Electrical contractor. The drawings are diagrammatic and all outlet locations must be verified at the time of installation.
- o The electrical contractor shall provide temporary electrical service for lighting and portable hand tools, and shall remove same when no longer required. (Includeing ground fault). Provide 120/208 volt, single phase service with minimum of 2-20 amp. circuits.
- o The electrical service shall conform to plans and specifications as well as utility requirements. The electrical contractor shall coordinate the service with the Kaukauna Electric and Water Company. Utility company costs will be paid by the Owner.
- o Motors and 208 volt controls furnished by mechanical trades, wired by electrical contractor, who shall also furnish the necessary disconnects. Contractor shall correlate closely with other trades for mounting requirements and conflicts, and include all costs for a complete workable installation.
- o Proposed circuiting shown on the panel schedules. Additional or alternate routing or circuits is left to the discretion of the contractor, however, any circuits judged by the Architect or his engineer to be overloaded or improperly derated shall be replaced by the contractor at his own expense.
- o The Electrical contractor shall provide materials as specified and shown on the drawings; or equal materials approved by the Architect.
- o All materials shall be U.L. listed and new. Switches shall be Sierra 5011/5013 or equal. Receptacles shall be Sierra 1910 or equal. Devices shall be ivory color unless directed otherwise.
- o Provide Electric-Eye Tork Model #3010, mounted a minimum of 12' high.
- o Fixture catalog numbers are general type numbers and along with description are intended to represent complete fixtures, including ballasts, sockets, back boxes, poles, mounting accessaries, and any other details required for a complete working installation. Use premium P ballasts for fluorescent fixtures.
- o Wire shall be new copper, and may be non-metallic cable system for general wiring per code. The Fire Alarm system shall be in a conduit system.
- o Install a complete non-coded Fire Alarm System as shown on the drawings, and described herein;
  - --Alarm panel shall be an Edwards #1520A, with #1522A-2 surface box for surface mounting. Uses 120/208 volt, 60 hz supply, or equal.
  - --Pull stations shall be Edwards #270-SPO; or equal.
  - --Horns shall be Edwards #884D-N5; or equal.
  - --Heat/Smoke Detectors shall be Edwards #281-A; or equal.
- o The telephone system shall be wired by the Wisconsin Telephone Company. The electrical contractor shall provide where shown on the electrical plan outlet boxes (3 per apartment), a 2' x 4' sheet of 5/8" plywood fastened to the utility room wall for telephone equipment, a 1½" conduit for telephone service entrance through the utility room floor and foundation wall, and a 120 volt, 15 amp. receptacle at the plywood sheet.
- o The electrial contractor shall provide outlet boxes for cable-TV installation where shown on the plans. Wiring for cable-TV shall be by Cablevision of the Fox Cities.
- o The television antenna system shall be by the Owner. Provide outlet boxes where shown on the plans.
- o The electrical contractor shall examine the heating drawings to determine the extent of work required for the electric heating system. The electrical contractor may bid the heating equipment as a separate bid, but must include all the HVAC work.
- o The electrical contractor shall remove his rubbish from the site as it accumulates.
- o The Contractor shall guarantee in writing all labor and materials for one year after final acceptance of the work hereunder.

GENERAL NOTES & SPECIFICATIONS

1. GENERAL CONDITIONS (pertains to all contractors & subcontractors)

- o The contractors are to furnish materials and labor to execute the work as shown on the drawings, as described herein, and/or as directed by the Architect or Construction Manager.
- o Workmanship shall be of the best quality. In as much as the specifications hereinafter are of a brief nature, it is the intent that each contractor provide workmanship that is neat, secure, with the best possible appearance and utility. The Architect will be judge of installed work and may reject work which does not meet the standards established hereby. Such rejected work shall be repaired or replaced to the satisfaction of the Architect without cost to the Owner.
- o Reference to materials or systems herein by name, make or catalog number is intended to establish a standard of quality, and not to limit competition; and the words "or approved equal" are implied following each brand name. "Or approved equal" materials shall be approved by the Architect prior to acceptance for use.
- o All contractors are responsible for the removal of their own refuse from the premises. The Construction Manager shall provide a dumpster on the site for the use of all trades and shall broom clean the job site at least every Friday. Final cleaning and washing of glass is by Others.
- o Temporary electrical power, temporary water service, a portable chemical toilet, and temporary heat as required will be provided for contractors and subcontractors by the Owner and/or CM.

DESIGN LOADINGS & GENERAL REQUIREMENTS

Design Data:	Roof Live Load -- Snow		30 psf
	Snow Drift Loads per ILHR 53.11		--
	Roof Service Load		3 psf
	Floor Live Load -- Living Areas		40 psf
	-- Corridors		80 psf
	-- Balconies		40 psf
	Wind Load		20 psf
Criteria:	Soil Bearing Capacity (Presumptive)		3,000 psf
	Concrete: Footings, slabs, etc.		3,000 psi
	Reinforcing Steel #3 Bars A615-40	fy =	40,000 psi
	#4 & Larger A615-60	fy =	60,000 psi
	Structural Steel - ASTM A36	fy =	36,000 psi
	Wood Framing - 2x4 bearing studs shall Douglas Fir Construction grade	fb =	1,450 psi
		fv =	95 psi
		E =	1,500 ksi
	Wood Framing:		
	MICRO-LAMS	Fbr =	2,800 psi
	2x8's, 2x10, 2x12's Joists & Headers	Fbr =	1,450 psi
	2x4, 2x6 Studs	Fbr =	1,150 psi

- o Contractors to cross check dimensions and elevations between architectural, mechanical, and structural drawings. Architect to be notified of any variance before contractor begins work. All equipment supports and anchorages to be cross checked with manufacturer's drawings. Contractor to verify all profiles, heights and dimensions at project, prior to fabrication of any materials / components and inform the architect of any discrepancies for framing interferences.
- o Shop Drawings: Submit a minimum of 6 copies for approval of shop drawing clearly showing details for accurate placing of reinforcing steel, structural steel, precast planking, timber members, steel joist, steel decking, etc. Separate material lists will not be accepted. Architect's approval does not relieve contractor of any responsibility for correctness, fit, or strength of details.

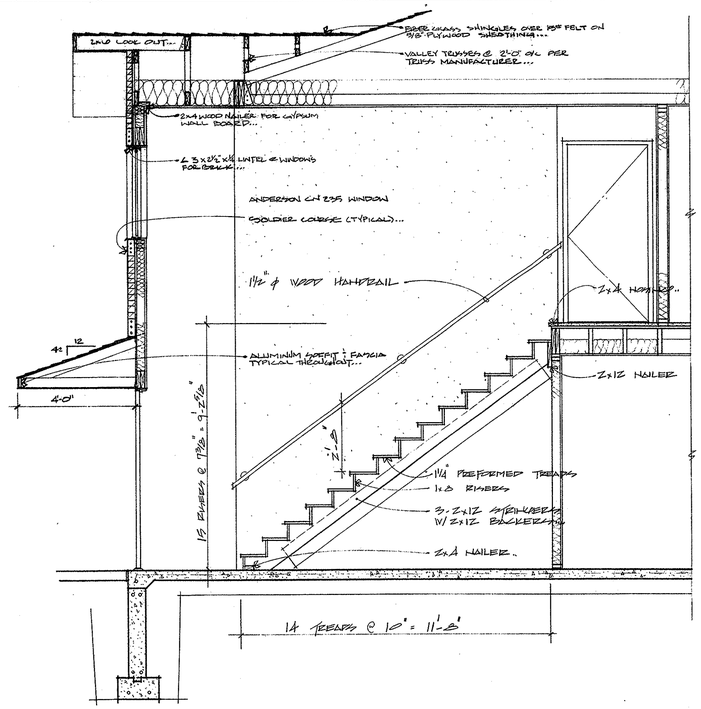
GENERAL NOTES continued from Sheet #1

2. DIVISION 2 -- SITE WORK

General:
- o The Buildings on the site shall be staked out and footing elevations set by the Construction Manager and shall be approved by the Architect before excavation is begun.
- o The location of utilities where shown on the drawings are based on available records and are not guaranteed to be complete or correct. The intention is to assist the contractors in making a determination of exact locations.
- o Soil bearing, samples, and testing was not done. Soil bearing capacity is assumed at 3,000 psf; sandy clay silt, firm inorganic silt per ILHR 53.12, Table 53-II. The contractor shall notify the Architect immediately if soils other than those indicated are encountered.
- o The electrical, telephone, and gas services shown shall be by the utility companies supplying service.

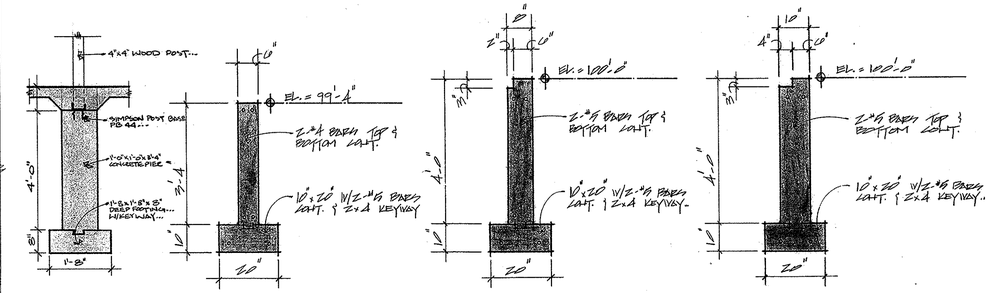
2A. Excavation:
- o Excavate to grade lines for footings, floor slabs, parking lot base, as shown on the drawings. Provide compacted granular fill to bring the grade under paved areas to within 6" of the required contours shown on the drawings or finished grades as determined in the field. Miscellaneous debris shall be hauled from the site and disposed of by the excavation contractor. Include all disposal costs in the bid. Stockpile at site material needed for backfilling and rough grading.
- o Footings shall bear on undisturbed soil. Backfill the interior of the building with sand fill placed in 6" to 8" lifts and compacted to 95% compaction as measured by a Standard Proctor test. Provide copies of the test result to the office of the architect for review. Backfilling around the exterior of the building may be with excavated earth at foundation walls with slabs on grade floors, if compacted uniformly. Excess excavated material if any shall be hauled from the site to a point within five miles (round trip) as designated by the Owner, or in the absents thereof, shall be hauled from the site and disposed of at the contractor's expense and option. Coordinate backfilling with the concrete contractor for placement of perimeter insulation.
- o At proposed parking lots and drives provide grades required for a minimum of 8" compacted gravel subbase. Areas below parking and drives shall be filled with compacted sand/pit run fill, compacted to 96% as measured by Standard Proctor test. Provide test results to the office of the Architect for review. Fill material shall be placed in maximum lifts of 8". Top 8" of subbase material shall be breaker run. Four (4") inch base for asphalt shall be furnished by the Asphalt Contractor.
- o After backfilling, rough grade the site to grade lines shown or to obtain the gradual slope from the buildings, drives, walks, etc. as shown to obtain the best possible drainage from the building site. Coordinate rough grading work with the landscape contractor. Spread top soil if any over the areas to be lawn, and fill all planting areas.
- o Trenching for utilities and backfilling of that work shall be by the utility contractor doing the work.

2B. Asphalt Paving:
- o The asphalt contractor is to provide the finished grading of the parking/paved areas and the top 4" of base material. Provide 4" compacted base material of crushed limestone. Provide asphalt concrete paving of 2" thickness. This contractor to layout work to provide drainage to the drainage ditches and/or catch basins shown. Include parking striping as shown on the site plan.



2C. Utilities:
- o This contractor is to furnish labor and materials to install the water service, sanitary laterals, and storm sewer systems as shown on the site plan required for each building. This contractor is to include in his bid all licenses, permits, and fees necessary to perform work, ready for final connection to the building by others.
- o All work shall conform to state and local codes, and shall meet the requirements of the utility and/or municipality providing the service.
- o All materials shall be approved and new. The storm laterals and sanitary laterals shall be Schedule 30 ABS or PVC. The water service shall be type "K" copper. All trench excavations shall be back filled in 8" to 12" layers lifts with compacted (to 96% by Proctor) sand or gravel fill. Unless noted otherwise on the plans, the catch basins shall be 36" in diameter x the depth shown on the site plan. The rim and grate shall be a Neenah Foundry #R-1660 w/Type "A" grate; or equal.

2D. Landscaping & Miscellaneous:
- o Landscape work and miscellaneous site work, such as fences, timber work, etc. shall be by separate proposal submitted to the Architect/Construction Manager. Proposals shall include plant lists with caliber or proposed stock. When requested, provide a landscape design proposal for approval.



3. DIVISION 3 -- CONCRETE

3A. Cast in Place:
- o Concrete work shall include all footings, walls, floor slabs, stoops, private walks, aprons, city walks, etc. shown on the drawings. This contractor shall stake out the buildings on the site and determine footing elevations.
- o All concrete shall be ready-mixed furnished by a reputable vendor in accordance with ASTM C94. Concrete shall be 3,000 psi compressive strength at 28 days; maximum aggregate size 3/4" in all concrete; maximum water/cement ratio 5:1, minimum 6 bag of cement per cu. yd.; 6% air entrainment (+/- 1%), and water shall be potable. Maximum slump for walls shall be not over 3" and for others 4".
- o Contractor shall be responsible for adequacy of design and construction of forms, centering, shoring, and bracing. As a minimum, the Contractor shall follow ACI Standard Recommended Practice for Concrete Formwork (ACI 347-63). Supports for forms and centering shall be sufficiently strong to carry both dead and live loads to which they will be subjected. Shoring and supports shall be adjustable to permit tightening, bracing, leveling, and cambering as required.
- o Reinforcing steel shall conform to ASTM-A615-40, fy = 40,000 psi. Reinforcing shall be suitably branded with rolled -in marks to visually establish the grade and size. Welded wire fabric reinforcement shall be electric welded, steel wire fabric conforming to ASTM-A285, 6" x 6" - 10/10. All reinforcing material shall be uncoated, unpainted, free from rust, scale, and dirt; and shall be placed in conformance with CRSI "Recommended Practice for Placing Bars", latest edition.
- o When the mean daily temperature of the atmosphere is less than 40 degrees F., the temperature of the concrete shall be maintained between 50 degrees and 70 degrees F. for the required curing period. When necessary, arrangements for heating, covering, insulating, or housing the concrete work shall be made in advance of placement and shall be adequate to maintain the required temperature and moisture conditions without injury due to concentration of heat. Cold weather requirements shall comply with ACT 306-66.
- o Slabs shall be placed on 4 mil (.004") polyethylene plastic film. Lap joints 6" minimum. Smooth dense steel trowel finish on all interior slabs. Slip resistant broom finish on walks and stoops.
- o This contractor is to provide and install the perimeter insulation shown on the drawings. Coordinate this work with the backfilling by the excavation contractor. Perimeter insulation shall be beaded styrofoam of R = 5.9; or equal, extending vertical to footings. Insulation shall be applied to wall with mastic approved by the insulation manufacturer. Let vertical members dry prior to backfilling; butt joints snug. Keep area between concrete and insulation free of backfill and other debris. Insulation exposed above grade shall be protected with fiberglass insulation guard applied with mastic and flashed into the wall structure (masonry or siding). All concrete form ties shall be removed prior to adhering insulation.
- o The lightweight concrete underlayment shall be as manufactured by Gyp-crete, Elastizell, or equal. This contractor shall furnish all labor and materials for installation as shown on the drawings. Application shall be by an approved applicator according to the manufacturer's printed specification. Plywood subflooring shall be primed, and underlayment layer a minimum of 1-1/2" thick.

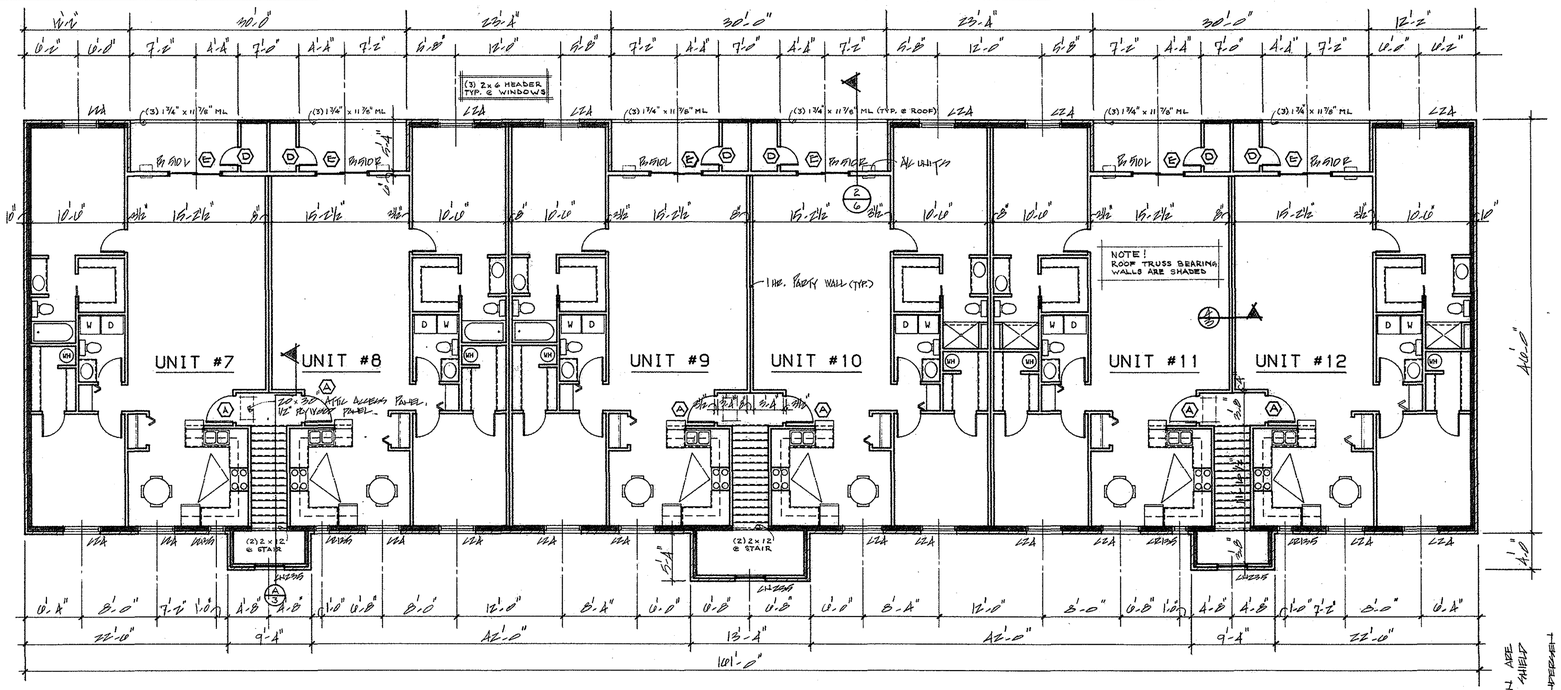
GENERAL NOTES continued from Sheet #3

4. DIVISION 4 -- MASONRY

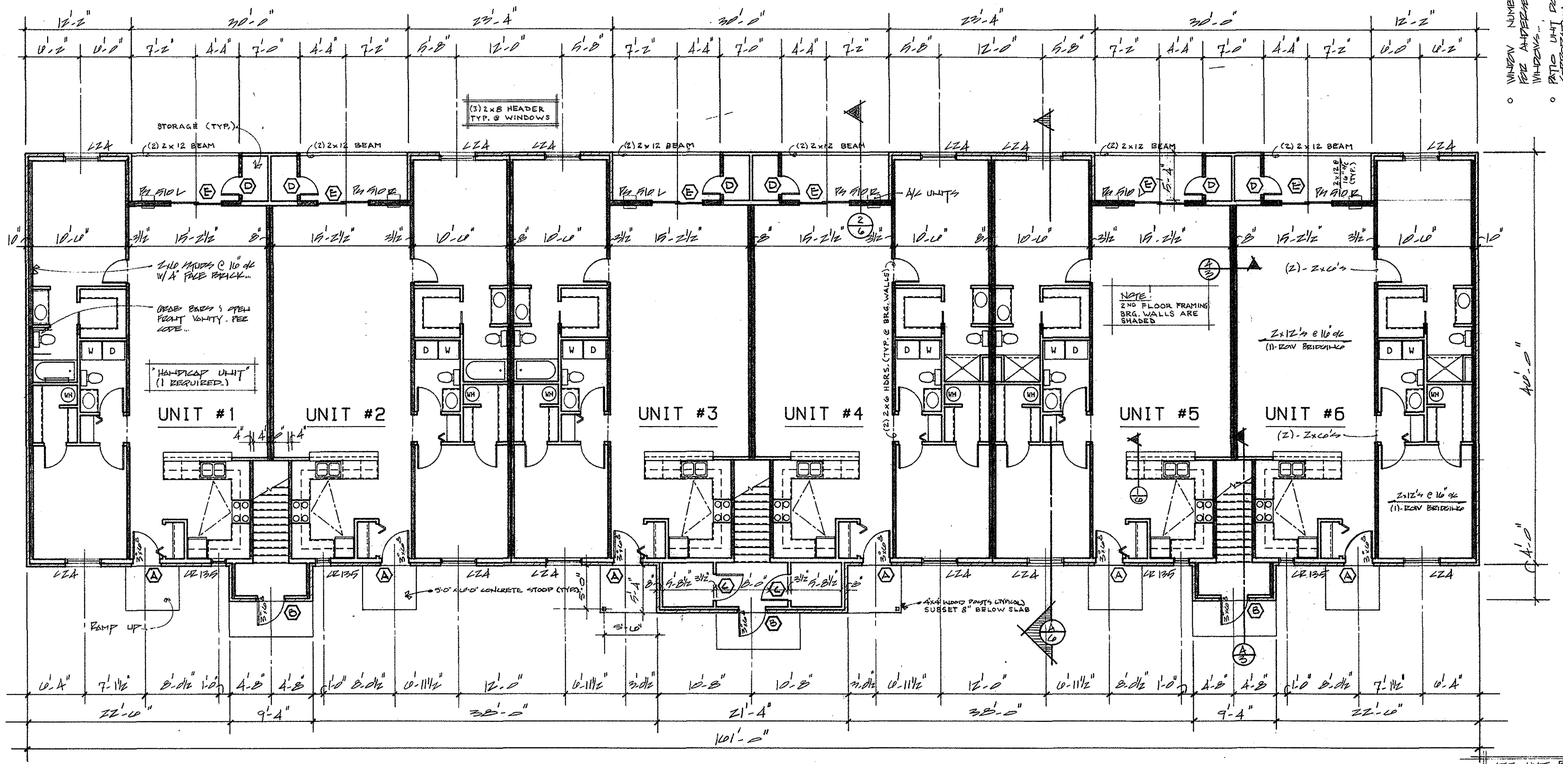
- o The general contractor shall furnish labor and materials for the masonry brick veneer work shown on the floor plans and building elevations.
- o Brick veneer masonry units shall be ASTM-C652 hollow clay units of modular size and laid in running bond with 3/8" joints. Color and final selection of brick shall be made by the Architect. The intent is to match the existing. Mortar shall be Type N, 1:1:6 mix of ruputable vendor with ASTM C144 sand and potable water. Mortar color shall be added according to the requirements of BIA. No air entraining admixtures or anti-freeze compounds may be added to the mortar. Provide 22 gage x 7/8" galvanized veneer ties at 16" o.c. each way.
- o Lay C.M.U. plumb and true to lines. Lay with completely filled mortar joints. Provide weep holes in head joints in first course immediately above all flashings by placing and leaving a sash cord in joint.
- o Masonry shall be left clean, free of stains, and acceptable by the Architect/Owner. Do not use cleaning agents other than water without approval of the Architect.
- o The contractor shall provide openings for ductwork as required by the HVAC drawings, and shall review the electrical drawings for outlet box and switch boxes required to be placed in masonry.
- o Cold weather construction shall be according to B.I.A. recommendations; a copy of which is available from the office of the Architect. When the mean daily temperature of the atmosphere is less than 40 degrees F or expected to be within 3 days, the masonry work shall be protected by temporary enclosure with temporary heat provided by the masonry contractor. The masonry contractor shall include in his bid the net cost per day for temporary heat. Temporary heat when required is to be approved in advance by the Architect.



5. DIVISION 5 -- STRUCTURAL STEEL & METALS

- o This contractor shall provide and erect all steel beams, columns, and lintels as shown on the drawings. Structural steel framing shall conform to ASTM A36 except structural tubes which shall comply with ASTM A500, grade B. All field connections for members to be made with high strength bolts ASTM A325N unless noted otherwise. Field welding in lieu of bolts to be used only with approval of the Architect. Field welds where shown shall be performed by a State of Wisconsin certified welder, in accordance with American Welding Society.
- o Structural steel framing shall be shop primed with one coat of the manufacturer's standard rust inhibiting primer. Provide holes, anchor bolts, bearing plates, as required for a complete job. All fabrication and erection shall be in accordance with the "Specification for Design, Fabrication, and Erection of Structural Steel for Buildings" by the American Institute of Steel Construction and in accordance with the Wisconsin Administrative Code, ILHR53.50.
- o Provide and maintain cross bracing of all structural steel erection until structural work is securely incorporated into construction to insure plumb and square alignment. Provide masonry anchor straps on columns where masonry abuts. Provide miscellaneous support angles as required for HVAC openings as required.
- o Provide shop drawings for approval to the office of the Architect.

6. DIVISION 6 -- CARPENTRY



- o The carpentry contract shall include all work under this division, and also supplying labor to install work under Division 7, except insulation; Division 8; (doors, windows, & hardware): and Division 10 (specialties).
- o Roof truss design and State of Wisconsin DILHR approval shall be the responsibility of the supplier prior to fabrication. Design for a superimposed roof load of 30 psf LL, 10 psf DL/TC, and 10 psf DL/BC. Provide shop drawings and State approved drawings.
- o **Structural bearing wall studs and miscellaneous floor joists shall be Douglas Fir Construction grade and Douglas Fir No. 2 as specified above.** Miscellaneous rough framing materials shall be as follows: 2 x 4's and 2 x 6's Southern Yellow Pine, or White Fir, No. 2 construction grade or better; 2 x 10's joist framing Douglas Fir-Larch #2 construction grade or better; with a moisture content not to exceed 20% and shall be kiln dried. Each piece of lumber shall bear the grade and trademark of its producers. Structural and framing lumber shall be S4S unless noted otherwise.
- o Floor joist shall be TJI-35 series joist as manufactured by The Truss Joist Corporation. The TJI joists shall be sized and detailed to fit the dimensions and loads indicated on the plans. All designs shall be in accordance with allowable values and section properties assigned and approved by the building code. Verification of design of the TJI joist by complete calculations is to be available upon request. The TJI joists are to be erected and installed in accordance with the plans, any Trus Joist drawings, and installation suggestions.
- o Plywood roof and wall sheathing shall be of size shown on the drawings of standard INT-APA grade "CDX" (with exterior glue) fir with ply clips if required. "Oxboard" sheathing may be substituted for plywood.
- o Subflooring shall be 5/8" INT-APA grade "CDX" plywood (with exterior glue).
- o Framing lumber and other rough work shall be closely fitted, accurately set to required lines and levels, and rigidly secured in place. Studs shall be sized to give true surfaces receiving finished materials. Partitions shall be framed with 2 x 4 studs spaced 16" on center, unless detailed otherwise. Plates of partitions resting on concrete floors shall be anchored in place with 1/2" bolts spaced not more than 6' apart. Studs shall be doubled at openings. Headers for openings shall be made of 2 pieces of material set on edge; depth to suit size of opening per applicable code. Corners shall be thoroughly spiked and made solid. End studs of partitions abutting concrete/masonry walls shall be securely anchored, using 1/2" bolts not over 4' o.c. Partitions shall be provided with blocking for trim, recessed cabinets, plumbing, and other work to be concealed. Nailing strips shall be cut-in as required for support of fixtures of all kind.
- o MICRO=LAM beams shall be as manufactured by the Trus Joist Corporation. MICRO=LAM lumber beams shall be designed to meet the dimensions and loads indicated on the plans. All designs shall be in accordance with standard engineering practice. Complete design calculation showing member forces and stresses and allowable load shall be available upon request for each MICRO=LAM lumber beams is to be under the supervision of a registered professional engineer and in accordance with the NRB acceptance, and provisions of The National Design Specification For Wood, 1984.
- o Finished carpentry shall be select oak as shown on the drawings with a moisture content not less than 6% or more than 15%. In no instance shall any woodwork be stored or installed in any area unless the entire area is broom clean, closed in, and possessing a relative humidity below 50% at 70 degrees F. All species shall contain only minor inherent natural defects, except that defects covered by adjoining members, concealed when the stock is installed, or not visible after pigmented finishing (as stain) may be admitted. Lengths shall be in the proportion available in the species and grade specified. Trim members shall be "backed-out" when 1-5/8" wide or wider, and for application on flat surfaces. Exposed surfaces shall be machine sanded on top face surfaces only, matching run otherwise. Working defects, as torn grain, machine marks, cross sanding, tool marks, etc. will not be permitted. Edges shall be milled straight and true, and then exposed corners shall be slightly rounded. Scribing and jointing shall be done accurately and neatly, so as to produce concealed and permanently tight joints, in a uniform plane for best appearance. Unless detailed otherwise, corners shall be mitered, except the inside corners shall be scribed; horizontal running trim shall butt vertical standing trim. Joints in horizontal running trim shall be scarfed, glued, and nailed. Where nailing is exposed, use finishing nails, counter-sunk.
- o Miscellaneous fasteners and rough carpentry hardware where not called out on the drawings shall be of a size and spacing which will develop the full strength of the members being fastened.
- o Cabinets shall be furnished and installed by others. Bid shall include the installation of backing materials as required.
- o This contractor shall provide closet shelving, rods, and miscellaneous trim work implied for a complete job.

GENERAL NOTES continued from Sheet #4

7. DIVISION 7 -- THERMAL & MOISTURE PROTECTION

7A. Insulation:

- Building wall insulation shall be standard fiberglass, 3-1/2" full thick, friction fits and unfaced batt insulation with an R = 19 value as shown on the drawings. Ceiling insulation shall be standard fiberglass or mineral fiber (rockwool) blown insulation to provide a total R-value = 46. Special care shall be taken to fill all voids between members, window frames, door frames, sleeves, mechanical piping, etc. to provide a completely insulated system. Framed areas are to be provided with a 4 mil (.004") polyethylene film vapor barrier.

7B. Thermal & Moisture Protection (by Carpentry Contractor)

- Roofing shall be a 225 pound fiberglass shingle, Class "A" similar to Johns-Mansville "Fire-Glass III, Seal-o-Matic," or equal. Color as selected by the Architect/Owner. Submit samples for approval. Apply one layer of #15 felt underlayment over plywood sheathing, lapping 2" at horizontal and 6" at vertical joints. At eaves provide a double layer two feet into interior space. Secure to hold in place. Install Type "D" galvanized or bronze P.V.S. roof edge and starter strip; project over edge of sheathing 3/8" to form a drip. Use fasteners of hot galvanized steel or aluminum (10-1/2 to 12 gauge) roofing nails having heads of at least 3/8" diameter. Use nails of sufficient length to penetrate sheathing. Seal perimeter edges of shingle with a roofing cement. Install shingles per manufacturer's standard specifications for the shingles used.
- Flashing and sheet metal shall be of a 26 ga. galvanized iron of best commercial grade, fabricated to the size and contour as shown on the drawings. Use galvanized where not exposed to view. For sheet metal flashings exposed to view, use 26 ga. polyvinyl steel similar to Color Klad as manufactured by Vincent Brass Co. Provide polyvinyl ethylene sheet flashing as noted on the drawings of 6 mil. thickness.
- Soffits and fascia system shall be of preformed aluminum similar to Rollex-3. Provide trim pieces and accessories for complete job. Color as selected by the Architect. Seamless gutters and downspouts shall be color matched of .032" and .024" aluminum respectively.
- All wood framing areas shall be covered /wrapped with Tyvek infiltration paper per the manufacturer's printed recommendations.

8. DIVISION 8 -- WINDOWS, DOORS & HARDWARE

- Windows numbers shown are Andersen Perma-Shield by the Andersen Corp. Final selection of the windows units to be used shall be made by the Owner/CM. Units shall be vinyl clad w/ the manufacturer's standard material. Glaze with the manufacturer's standard double pane insulating glass, provide insect screen, and extension jambs as required per the window details shown.
- Apartment door units shall be cored for locksets, dead bolts, "peep hole", and prepared for a knocker.
- Wood doors shall be as shown on the door schedule sheet #A-7. Doors shall be solid core (standard "K" core) with Red Oak face veneer; or hollow core with Red Oak face veneer as scheduled. Doors shall be AWI "Premium" grade or better. Door jambs and casings shall be solid oak milled material.
- Bi-fold closet doors shall be the same as above or as scheduled, with bi-fold hardware.
- Hollow metal doors shall be 1-3/4" thick with skin sheeting of 18 gauge steel with fiber core fill. Shop prime. Frame assemblies shall be 14 gauge and shall be provided with anchorage devices as required. Shop prime and prepare for hardware. Submit shop drawings for approval. Doors and frames shall be reinforced to accept finish hardware per the manufacturer's recommendations.
- All doors and frames shall be hung and set true and with uniform clearance along the edges. Prepare doors for grilles if any, and glazing as shown on the door schedule. Grilles to be furnished by the door supplier (see HVAC drawings).
- Finish hardware bids shall be submitted with a proposed hardware schedule prepared by the supplier. In general, apartment hardware shall be Schlage residential series Light Duty F series "Georgian style". Apartment doors shall be furnished with lockset, dead bolts, view holes, and knockers. Other hardware shall be Schlage "D" series, with LCN closers, Hager hinges, etc.; or approved equals.
- Apartment and garage interior door units shall be Peachtree "Avanti" model #A100, #A300, A31C; or equal. Doors shall be constructed of 24 ga. galvanized steel faces over a foamed-in-place polyurethane core. Unit shall be 1-3/4" thick, have an R-value=14.1 and be fire rated per ASTM E-152 of 3/4 hour (C-label). Doors shall be weather stripped and have the standard threshold.
- Overhead doors shall be steel sectional upward acting Raynor "Decade R/S" Series Residential garage doors; or equal. Door shall be constructed of 24 gauge galvanized steel and shall be a four panel, four section prefinished acrylic baked on enamel. Door shall be insulated with 1-3/8" expanded polystyrene with fire retardant additive. Track shall be 2" regular head room, with torsion spring operation. Provide weather stripping four (4) sides perimeter of doors. Doors shall be warranted for one year against defective materials and workmanship. Install per the manufacturer'e written specifications.

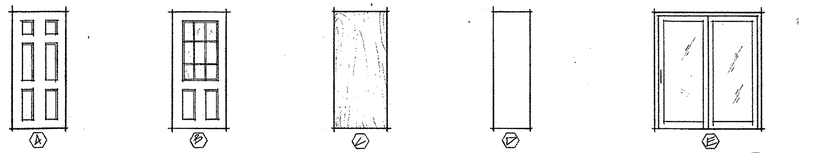
9. DIVISION 9 -- FINISHES

- Carpeting, sheet vinyl, and ceramic tile work shall be as directed by the Owner and / or Construction Manager.

9A. Gypsum Wall Board:

- Gypsum base board (drywall) shall be 1/2" and 5/8" as shown, of regular and fire core (type X), 4'-0" x lengths as required. Use 5/8" for 24" centers and 1/2" all others. Fasteners shall be power driven, type "S" bugle head, 1" long. Provide all accessories necessary for an installation per the manufacturer's printed specifications. See Room finish schedule sheet #4.
- Gypsum board shall be finished with a three coat system, with a fourth/final spray coating with sand textured finish.

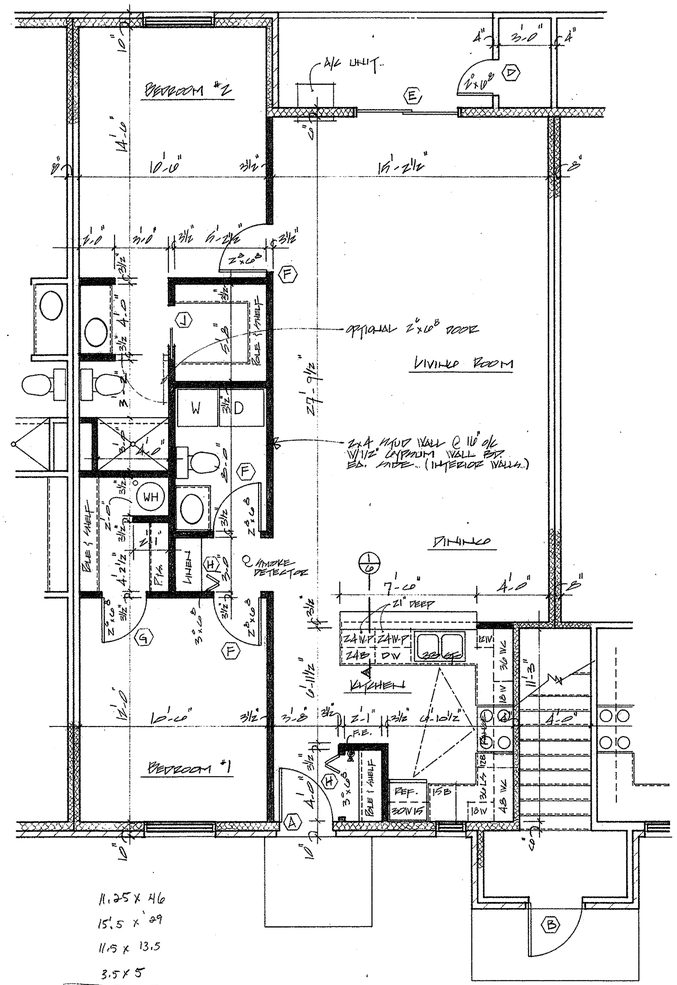
9B. Painting & Staining:



- Painting and staining shall be by an established firm.
- The painting contractor shall furnish labor and materials to stain and varnish with a three coat system (stain, sealer, varnish) all exposed wood surfaces, including tops and bottoms of all doors. In general, this includes doors, frames, windows, castings, handrails, baseboard, and shelving, (cabinets are prefinished). Verify with CM other materials prefinished and the extent of work regarding this section.
- Paint all gypsum surfaces with two coats (plus primer if required for good coverage) system of flat latex except kitchen and bathrooms, which shall have a final coat of semi-gloss latex. Colors for all coats as selected by the Owner. Submit to this office a color chart from the proposed manufacturer.
- Each container shall be labeled by the manufacturer stating type of paint, color of paint, and instructions for reducing. Brush roll, or spray materials smoothly in solid, even colors without drops, runs, lumps, defective brushing, discoloration or clogging of lines and angles. Make edges of paint adjoining other materials or colors sharp and clean, without overlapping. Apply per manufacturer's printed recommendations.
- Hollow metal doors & frames shall be coated with two coats of an oil base flat enamel. Colors as selected by the Owner.

10. DIVISION 10 -- SPECIALTIES

- Provide an allowance for shower rod, bathroom towel bar (30") and paper holder for installation in all each bathroom. Final selection of hardware to be made by the Owner.
- Fire extinguishes shall be "Kidde" model #6TPS; 2A-40BC, 6 lb./gal. extinguishes, or approved equal. Provide recessed cabinets for installation by others. Submit shop drawings & installation instructions. Units shall be red, with break glass entrance.
- Smoke detectors shall be provided where shown on the electrical plan. Detectors shall be ionization units, with test button, solid state, white polymer housing, powered by a 9-volt alkaline battery, similar to First Alert, or equal. (25 required thus).
- Appliances by Owner/CM per building; Ranges (12), Refrigerators (12), Ductless Range Hoods (12), Dishwashers (12).



15. & 16. DIVISIONS 15A, 15B, & 16.

- Mechanical & Electrical System specifications and notes are found on the mechanical plans. Bids shall be submitted separately as base bids.

SHEET
HVAC -1
7 of 12

1. SCOPE
   A. THE WORK COVERED BY THIS DIVISION OF THE SPECIFICATIONS WILL BE AWARDED AS A SEPARATE CONTRACT AND INCLUDES THE FURNISHING OF ALL LABOR, MATERIALS, TOOLS, EQUIPMENT, TRANSPORTATION, PERMITS, CERTIFICATES AND TEMPORARY PROTECTION NECESSARY FOR OR INCIDENTAL TO EXECUTING AND COMPLETING THE RELATED WORK AS HEREIN SPECIFIED OR AS INDICATED ON THE DRAWINGS.

   B. WORK EXCLUDED FROM THIS CONTRACT INCLUDES: LINE VOLTAGE, ELECTRICAL WIRING AND CONNECTIONS TO EQUIPMENT.

2. GENERAL REQUIREMENTS
   A. THE CONTRACTOR SHALL LAY OUT HIS WORK AND SHALL BE RESPONSIBLE FOR ITS CORRECTNESS. HE SHALL TAKE SUCH MEASUREMENTS AS MAY BE NECESSARY TO ASSURE APPROVED FITTING AND PROPER INSTALLATION OF HIS WORK, AND ALL OTHER WORK DEPENDING THERON

   B. HEATING CONTRACTOR SHALL COOPERATE WITH OTHER CONTRACTORS TO AVOID COMPLICATIONS BETWEEN INSTALLATION OF HEATING AND VENTILATING EQUIPMENT AND EQUIPMENT INSTALLED BY OTHERS.

   C. THE HEATING CONTRACTOR SHALL ESPECIALLY CONFER WITH THE ELECTRICAL CONTRACTOR TO AVOID INTERFERENCES; WHEN DIFFERENCES OF OPINION RESULT AS TO THE USE OF AVAILABLE SPACE, THE OPINION OF THE ARCHITECT SHALL GOVERN SUCH A CONTROVERSY.

   D. THIS CONTRACTOR SHALL VISIT THE SITE AND VERIFY EXISTING CONDITIONS, LOCATIONS AND REQUIREMENTS. IT IS THE CONTRACTORS RESPONSIBILITY TO BE FAMILIAR WITH ALL REQUIREMENTS OF EXISTING AND REQUIRED ADDITIONS TO COMPLETE THE INSTALLATION IN COMPLETE COMPLIANCE WITH THE INTENT OF THE PLANS AND SPECIFICATIONS. NO ADDITIONS WILL BE ALLOWED FOR ITEMS OVERLOOKED.

3. CODES AND PERMITS
   A. ALL WORK AND MATERIAL SHALL COMPLY WITH ALL FEDERAL, STATE AND LOCAL CODES AND ORDINANCES. CONTRACTOR SHALL OBTAIN ALL NECESSARY PERMITS AS APPLICABLE TO WORK UNDER THIS CONTRACT.

4. GUARANTEE
   A. THE CONTRACTOR MUST GUARANTEE THAT ALL OF THE MATERIAL FURNISHED BY HIM IS OF A QUALITY AS SPECIFIED AND FREE FROM DEFECTS IN VERY RESPECT, AND IF SO ORDERED BY THE ARCHITECT, HE SHALL REMOVE ANY DEFECTIVE MATERIAL AND REPLACE THE SAME WITH MATERIAL OF PROPER QUALITY. ALL WORK SHALL BE QUARANTEED AGAINST ORIGINAL DEFECTS IN WORKMANSHIP AND MATERIAL FOR A PERIOD OF ONE YEAR FROM DATE OF FINAL ACCEPTANCE OR OCCUPANCY BY THE OWNER, WHICHEVER IS EARLIER. ANY DEFECTIVE WORKMANSHIP OR MATERIAL DEVELOPING WITHIN THAT TIME SHALL BE REPLACED FREE OF COST TO THE OWNER.

5. SHOP DRAWINGS
   A. SUBMIT FOUR (4) SETS OF DRAWINGS FOR ALL EQUIPMENT TO THE ARCHITECT FOR APPROVAL. SUBMITTALS SHALL INCLUDE AIR CONDITIONERS, FANS, ELECTRIC HEATERS AND TEMPERATURE CONTROLS.

6. CUTTING & REPAIRING
   A. CONTRACTOR SHALL DO ANY NECESSARY CUTTING OF WALLS, PARTITIONS AND FLOORS AND SHALL PATCH UP AROUND SUCH CUTTING IN SUCH MANNER AS TO LEAVE THE BUILDING IN GOOD CONDITION. ALL SUCH CUTTING AND RESTORATION IS TO BE PERFORMED UNDER THE DIRECTION OF AND TO THE SATISFACTION OF THE OWNER. THE CONTRACTOR SHALL COOPERATE WITH OTHER CONTRACTORS TO REDUCE CUTTING TO THE VERY MINIMUM.

7. PIPING
   A. FLEX DUCTS FROM EXHAUST FANS SHALL BE PIPED BY THIS CONTRACTOR. VERIFY LOCATION AND REQUIREMENTS.

8. CONTROL SEQUENCE
   A. THERMOSTAT SHALL CYCLE HEATING OR COOLING EQUIPMENT TO MAINTAIN SPACE TEMPERATURE.

9. EQUIPMENT
   A. AC-1 SHALL BE EQUAL TO WHITE-WESTINGHOUSE OF MODEL, SIZE, AND CAPACITY INDICATED ON PLAN. UNITS SHALL HAVE A WALL SLEEVE THAT ENABLES CHASSIS TO SLIDE INTO AND COME COMPLETE WITH TWO SPEED COOLING FAN, ADJUSTABLE AIR DEFLECTORS, BUILT IN THERMOSTAT, AND VENTILATION CONTROL.

   B. EXHAUST FANS SHALL BE BROAN OR EQUAL OF CAPACITIES AND EQUAL TO MANUFACTURERS AS SHOWN ON PLANS, ALL FANS SHALL BE FURNISHED COMPLETE WITH BACKDRAFT DAMPERS, DISCONNECTS AND BIRD GUARDS AS REQUIRED.

   C. ELECTRIC HEATERS SHALL BE EQUAL TO T.P.I. OF MODELS AND CAPACITIES AS SHOWN, ALL UNITS SHALL BE COMPLETE WITH UL LABELS AND BE INSTALLED IN COMPLIANCE WITH MANUFACTURER'S REQUIREMENTS AND ALL APPLICABLE CODES.

10. ELECTRICAL HEATERS
   A. ELECTRIC HEATERS SHALL BE T.P.I. OR EQUAL OF SIZES AND CAPACITIES INDICATED ON PLANS. UNIT SHALL BE U.L. LISTED AND HAVE ALL SAFETY AND OPERATING CONTROLS NECESSARY. PROVIDE HEATERS WITH ALL NECESSARY COMPONENTS REQUIRED FOR PROPER INSTALLATION.

11. CONCRETE PADS.
   A. ALL CONCRETE PADS FOR MECHANICAL EQUIPMENT WILL BE FURNISHED BY H.V.A.C. CONTRACTOR.

12. LUBRICATION
   LUBRICATE ALL EQUIPMENT PRIOR TO INITIAL START UP IN ACCORDANCE WITH MANUFACTURER'S INSTRUCTIONS. ALL LUBRICATION POINTS SHALL BE CLEARLY MARKED.

   FURNISH A LUBRICATION SCHEDULE LISTING ALL POINTS OF LUBRICATION FOR EACH PIECE OF MECHANICAL EQUIPMENT, FREQUENCY OF LUBRICATION, AND TYPE OF LUBRICANT REQUIRED AT EACH POINT.

13. HOUSEKEEPING
   IT SHALL BE THE DUTY OF THIS CONTRACTOR TO KEEP THE BUILDING CLEAN AND FREE OF DEBRIS DURING THE INSTALLATION OF HIS WORK.

14. TESTING AND BALANCING
   THE FINAL PAYMENT TO THE HEATING CONTRACTOR WILL NOT BE MADE UNTIL THE SYSTEM HAS BEEN THOROUGHLY TESTED AND FOUND TO BE IN GOOD ORDER AND IN FIRST CLASS OPERATING CONDITION IN EVERY PARTICULAR.

15. INSTRUCTIONS

   OPERATIONAL INSTRUCTIONS: COPIES OF STANDARD OPERATIONAL INSTRUCTIONS SHALL BE FURNISHED TO THE OWNER FOR ITEMS OF EQUIPMENT INCLUDED IN THIS CONTRACT.

   MAINTENANCE INSTRUCTIONS: THE CONTRACTOR SHALL REVIEW WITH THE OWNER'S REPRESENTATIVE, COMPLETE MAINTENANCE PROCEDURES FOR EQUIPMENT INSTALLED UNDER THIS CONTRACT.

16. ELECTRICAL REQUIREMENTS

   THE HEATING AND VENTILATING CONTRACTOR SHALL FURNISH ALL STARTING EQUIPMENT AND CONTROLS NECESSRY FOR OPERATION OF EQUIPMENT FURNISHED UNDER THIS DIVISION THE ELECTRICAL CONTRACTOR SHALL DO ALL LINE VOLTAGE WIRING.

   THE HEATING AND VENTILATING CONTRACTOR SHALL FURNISH ALL NECESSARY WIRING DIAGRAMS, CONTROL SEQUENCE DRAWINGS, ETC., AS MAY BE REQUIRED FOR COORDINATION OF WORK BETWEEN CONTRACTORS.

   STARTERS SHALL BE ALL OF SAME MANUFACTURE AND SHALL BE MAGNETIC, ACROSS THE LINE TYPE OF SIZE NECESSARY TO OPERATE THE MOTOR OR SYSTEM IT CONTROLS. THE ELECTRICAL CONTRACTOR WILL FURNISH NECESSARY, ADEQUATE DISCONNECTS WITHIN SITE OF MOTOR LOCATION.

17. FINALLY
   THIS CONTRACT CONTEMPLATES AND COMPRISES A COMPLETE AND WORKMANLIKE INSTALLATION OF LHEATING AND VENTILATING SYSTEM AS HEREIN BEFORE SPECIFIED AND ANYTHING NECESSARY TO THAT RESULT IS HEREBY INCLUDED THE SAME AS IF PARTICULARLY MENTIONED.

   WHEN COMPLETED, THE CONTRACTOR SHALL REMOVE ALL DEBRIS, TOOLS, MACHINES, AND APPARTUS OF EVERY SORT BELONGING TO HIM, LEAVING THE PREMISES FREE FROM ANYTHING OF THE KIND.

MATERIAL SAFETY DATA SHEET

Dow Chemical U.S.A.* Midland, MI 48674 Emergency Phone: 517-636-4400

Product Code: 81982 Page: 1

PRODUCT NAME: STYROFOAM (R) BRAND SCORE BOARD EXTRUDED POLYSTYRENE INSULATION (2 INCH)

Effective Date: 07/31/89 Date Printed: 12/13/89 MSDS:002462

1. INGREDIENTS: (% w/w, unless otherwise noted)

Polystyrene	CAS# 009003-53-6	Balance
Dichlorodifluoromethane	CAS# 000075-71-8	0-7.5%
Chlorodifluoroethane	CAS# 000075-68-3	0-9.5%
Ethyl chloride	CAS# 000075-00-3	0-4.0%
Polyethylene	CAS# 009002-88-4, or CAS# 026221-73-8	0-6.0%
Hexabromocyclododecane (HBCD)	CAS# 003194-55-6	0-2.0%
Pentabromomonochlorocyclohexane	CAS# 000087-84-3	0-2.0%

This document is prepared pursuant to the OSHA Hazard Communication Standard (29 CFR 1910.1200). In addition, other substances not 'Hazardous' per this OSHA Standard may be listed. Where proprietary ingredient shows, the identity may be made available as provided in this standard.

2. PHYSICAL DATA:

BOILING POINT: Not applicable
VAP. PRESS: Not applicable
VAP. DENSITY: Not applicable
SOL. IN WATER: None
SP. GRAVITY: .027 To .064
APPEARANCE: Rigid cellular foam board.
ODOR: No odor.

3. FIRE AND EXPLOSION HAZARD DATA:

FLASH POINT: 670F, 354C Flash ignition temperature.
METHOD USED: ASTM D1929 Proc. B.

FLAMMABLE LIMITS
LFL: Not applicable.
UFL: Not applicable.

(Continued on Page 2)
(R) Indicates a Trademark of The Dow Chemical Company

* An Operating Unit of The Dow Chemical Company

3. FIRE AND EXPLOSION HAZARD DATA: (CONTINUED)

EXTINGUISHING MEDIA: Water fog.

FIRE & EXPLOSION HAZARDS: Emits dense, black smoke when burned.

Certain operations, such as grinding or cutting, may lead to a buildup of dust suspended in air which can cause a dust explosion if ignited. Provide adequate ventilation, and appropriate dust handling systems.

FIRE-FIGHTING EQUIPMENT: Wear positive-pressure, self-contained breathing apparatus.

Apply large volume of water directly on flame or burning surface.

4. REACTIVITY DATA:

STABILITY: (CONDITIONS TO AVOID) Avoid fire and high temperatures. Temperatures over 300C (572F) will release combustible gases.

INCOMPATIBILITY: (SPECIFIC MATERIALS TO AVOID) Aromatic hydrocarbons, higher (>C5) aliphatic hydrocarbons, esters, amines, higher aldehydes.

HAZARDOUS DECOMPOSITION PRODUCTS: Does not normally decompose. In smoldering or flaming conditions, carbon monoxide, carbon dioxide, carbon are generated. Evolution of small amounts of hydrogen bromide, hydrogen chloride and hydrogen fluoride occurs when burned or heated over 250C (482F); under high heat, non-flaming conditions, small amounts of aromatic hydrocarbons such as styrene and ethylbenzene are generated.

Studies have found that the products of combustion of this

(Continued on Page 3)

(R) Indicates a Trademark of The Dow Chemical Company

4. REACTIVITY DATA: (CONTINUED)

polystyrene foam insulation are no more acutely toxic than the products of combustion of other common building material such as wood.

HAZARDOUS POLYMERIZATION: Will not occur.

5. ENVIRONMENTAL AND DISPOSAL INFORMATION:

ACTION TO TAKE FOR SPILLS/LEAKS: Pick up, or if dust or in small pieces, sweep up and place in suitable container for disposal.

DISPOSAL METHOD: Bury in an approved landfill, or burn in an adequate incinerator with excess oxygen, in accordance with all local, state and federal regulations.

HEALTH HAZARD DATA:

EYE: Solid or dust may cause irritation or corneal injury due to mechanical action.

SKIN CONTACT: Mechanical injury only. Essentially nonirritating to skin.

SKIN ABSORPTION: Skin absorption is unlikely due to physical properties.

INGESTION: Ingestion is unlikely due to physical state. Physical injury only. May cause choking if swallowed.

INHALATION: Dust may cause irritation to upper respiratory tract. Excessive exposure to high concentrations of the ethyl chloride, dichlorodifluoromethane, and chlorodifluoroethane blowing agents may cause central nervous system depression, anesthetic effects and irregular heartbeats (cardiac sensitization). In animals, excessive exposure to chlorodifluoroethane has caused low blood

(Continued on Page 4)

(R) Indicates a Trademark of The Dow Chemical Company

* An Operating Unit of The Dow Chemical Company

6. HEALTH HAZARD DATA: (CONTINUED)

pressure, respiratory stimulation and tightness in the chest (bronchoconstriction). Concentrations of the above blowing agents anticipated incidental to proper handling are expected to be well below those which cause the acute inhalation effects listed above, as well as below the OSHA PEL and Dow Industrial Hygiene Guide. (See Section 8 for Handling Precautions.)

SYSTEMIC (OTHER TARGET ORGAN) EFFECTS: Repeated exposures to dusts of this material are not anticipated to result in systemic toxicity or permanent lung injury; however, excessive exposures may cause less severe respiratory effects. Pentabromomonochlorocyclohexane is essentially encapsulated in the polymer, but when tested separately, it caused liver and kidney effects; pentabromomonochlorocyclohexane and hexabromocyclododecane (HBCD) may increase tissue levels of bromine.

CANCER INFORMATION: Neither polystyrene foam dust, dichlorodifluoromethane nor chlorodifluoroethane caused cancer in long-term animal studies. An increase in uterine tumors has been reported in female mice exposed for their lifetimes to 15,000 ppm ethyl chloride. Such tumors did not occur in rats similarly exposed. These results are of unknown relevance to humans. Pentabromomonochlorocyclohexane is essentially encapsulated in the polymer, but when tested separately it has been shown to cause cancer in laboratory animals, but only at doses producing other toxic effects.

TERATOLOGY (BIRTH DEFECTS): No birth defects were seen in animal studies with dichlorodifluoromethane, ethyl chloride or chlorodifluoroethane.

REPRODUCTIVE EFFECTS: Dichlorodifluoromethane has been reported to have no adverse effects on reproduction in rats.

MUTAGENICITY (EFFECTS ON GENETIC MATERIAL): Results of tests for genetic effects with dichlorodifluoromethane, HBCD and pentabromomonochlorocyclohexane have been negative. Ethyl

(Continued on Page 5)

(R) Indicates a Trademark of The Dow Chemical Company

* An Operating Unit of The Dow Chemical Company

6. HEALTH HAZARD DATA: (CONTINUED)

chloride and chlorodifluoroethane have been shown to be negative in some in vitro (test tube) mutagenicity tests and positive in others. Results of mutagenicity tests in animals on chlorodifluoroethane have been negative.

7. FIRST AID:

EYES: Irrigate immediately with water for at least 5 minutes; mechanical effects only.

SKIN: No adverse effects anticipated by this route of exposure.

INGESTION: No adverse effects anticipated by this route of exposure.

INHALATION: Remove to fresh air if effects occur. Consult a physician.

8. HANDLING PRECAUTIONS:

EXPOSURE GUIDELINE(S): Ethyl chloride: Dow Industrial Hygiene Guide (IHG) is 150 ppm; ACGIH TLV and OSHA PEL are 1000 ppm. Dichlorodifluoromethane: ACGIH TLV and OSHA PEL are 1000 ppm. Pentabromomonochlorocyclohexane: Dow Industrial Hygiene Guide (IHG) is 3 mg/m3.

VENTILATION: Provide general and/or local exhaust ventilation to control airborne levels below the exposure guidelines.

RESPIRATORY PROTECTION: Atmospheric levels should be maintained below the exposure guideline. When respiratory protection is required for certain operations, use an approved air-purifying respirator. In dusty atmospheres, use an approved dust respirator.

(Continued on Page 6)

(R) Indicates a Trademark of The Dow Chemical Company

8. HANDLING PRECAUTIONS: (CONTINUED)

SKIN PROTECTION: No skin protection should be needed.

EYE PROTECTION: Safety glasses should be sufficient for most operations; however, for dusty operations wear chemical goggles.

9. ADDITIONAL INFORMATION:

REGULATORY REQUIREMENTS:

SARA HAZARD CATEGORY: This hazard category classification is listed solely to assist with federal laws under SARA Title III. This classification is not intended nor appropriate for evaluating safe handling and use of this product. Refer to the body of this material safety data sheet for health and safety information. According to the EPA "Hazard Categories" promulgated under Sections 311 and 312 of the Superfund Amendment and Reauthorization Act of 1986 (SARA Title III) this product is considered under applicable definitions to meet the following categories:

An immediate health hazard
A delayed health hazard

SPECIAL PRECAUTIONS TO BE TAKEN IN HANDLING AND STORAGE: Limited industrial hygiene measurements of ethyl chloride in ventilated warehouses and production facilities indicate that ethyl chloride present in the air is below the current 150 ppm Industrial Hygiene Guide for ethyl chloride.

Gas fired recirculating air furnaces or heaters, gas water heaters, etc., drawing air from areas where there may be a

presence of ethyl chloride, dichlorodifluoromethane and chlorodifluoroethane gases from storage or fabrication of extruded polystyrene foam, can be subjected to rust and corrosion problems as a result of thermal decomposition of the blowing agents to hydrogen chloride.

(Continued on Page 7)
(R) Indicates a Trademark of The Dow Chemical Company

9. ADDITIONAL INFORMATION: (CONTINUED)

This extruded polystyrene insulation will burn and should be handled and installed properly. Use only as directed by the specific instructions for this product. This insulation contains a flame retardant additive to inhibit accidental ignition from small fire sources. During shipping, storage, installation and use this material should not be exposed to flame or other ignition sources.

This foam product should not be stored or used in confined, virtually airtight spaces to prevent buildup of combustible vapors.

MSDS STATUS: Revised sections 1, 3, 4, 6, 7, 8, and 9.

SARA 313 INFORMATION:
This product contains the following substances subject to the reporting requirements of section 313 of Title III of the Superfund Amendments and Reauthorization Act of 1986 and 40 CFR Part 372:

CHEMICAL NAME	CAS NUMBER	CONCENTRATION
CHLOROETHANE (ETHYL CHLORIDE)	000075-00-3	<4 %

(R) Indicates a Trademark of The Dow Chemical Company
The Information Herein Is Given In Good Faith, But No Warranty,

Express Or Implied, Is Made. Consult The Dow Chemical Company For Further Information.

October 9, 2006

Clay Eiting
Ghost Town Fitness Center, LLC
180 Fox Shores Drive
Kaukauna, WI 54130

SUBJECT: Final Case Closure with PAL Exemption by Closure Committee for **Ghost Town Fitness Center**, 180 Fox Shores Dr, Kaukauna, WI
WDNR BRRTS Activity #: 02-45-547911

Dear Mr. Eiting:

On October 3, 2006, the Northeast Regional Closure Committee reviewed the above referenced case for closure. This committee reviews environmental remediation cases for compliance with state laws and standards to maintain consistency in the closure of these cases.

On October 6, 2006, the Department received documentation for abandonment of the monitoring well, indicating that you have complied with the final requirements of closure. Based on the correspondence and data provided, it appears that your case has been remediated to Department standards in accordance with s. NR 726.05, Wis. Adm. Code. The Department considers this case closed and no further investigation, remediation or other action is required at this time.

Recent groundwater monitoring data at this site indicates exceedances of the NR 140 preventive action limit (PAL) for arsenic and selenium at monitoring well, MW-1, but compliance with the NR 140 enforcement standard. The Department may grant an exemption to a PAL for a substance of public health concern, other than nitrate, pursuant to s. NR 140.28(2)(b), Wis. Adm. Code, if all of the following criteria are met:

1. The measured or anticipated increase in the concentration of the substance will be minimized to the extent technically and economically feasible.

2. Compliance with the PAL is either not technically or economically feasible.

3. The enforcement standard for the substance will not be attained or exceeded at the point of standards application.

4. Any existing or projected increase in the concentration of the substance above the background concentration does not present a threat to public health or welfare.

Based on the information you provided, the Department believes that the above criteria have been or will be met. Therefore, pursuant to s. NR 140.28(2)(b), Wis. Adm. Code, an exemption to the PAL is granted for arsenic and selenium at MW-1. This letter serves as your exemption.

Please be aware that this case may be reopened pursuant to s. NR 726.09, Wis. Adm. Code, if additional information regarding site conditions indicates that contamination on or from the site poses a threat to public health, safety or welfare, or the environment.

If you have any questions regarding this letter, please contact me at the number below.

Sincerely,

Jennifer Borski

NER Closure Committee – Lauridsen, Chronert, Polczinski

FROM: Jennifer Borski, DNR, RR, Oshkosh JB

SUBJECT: Request for Closure with PAL Exemption

SITE NAME: Ghost Town Fitness Center

WDNR BRRTS #: 02-45-547911

FAST TRACK – Financing dependent upon committee determination.

The lending bank required a Phase I be performed for a property transfer. The Phase I identified several past land uses of concern. At the requirement of the bank, Terracon performed a limited site assessment and installed one soil boring for soil and groundwater sampling in a location common to all land uses of concern in July 2006, which is currently in a gravel parking lot. Soils and groundwater were analyzed for DRO, VOCs and RCRA metals. DRO and VOCs were not detected in soil. Metals were not detected above standards in soil. The groundwater was collected from a 1" diameter, two-foot screen with water at 4 ft and identified three PAL exceedances (arsenic, lead and selenium). The temp well was replaced with a NR 141 well in September 2006, screened 3.5 to 13.5 ft bgs, and sampled. Two of the three PAL exceedances were confirmed (arsenic and selenium).

Groundwater Results (ppb)

Compound	1" diam geoprobe well	NR 141 MW-1	PAL	ES
Sample Date	7/26/06	9/12/06		
Arsenic	*7.8*	*3.0*	1	10
Lead	*5.8*	<0.7	1.5	15
Selenium	*32*	*14.7*	10	~~100~~ 50 KRL

Italics = PAL exceedance

I recommend closure with a PAL exemption for arsenic and selenium at MW-1.

Re: Limited Groundwater Assessment
Ghost-town Fitness Center
180 Fox Shores Drive
Kaukauna, Wisconsin
WDNR BRRTS #02-45-547911
Terracon Project No. 38067037

FEE RECEIVED
$750
Date 9/22/06 #4296
WDNR - NER

Dear Ms. Borski:

On behalf of Ghost-town Fitness Center, Terracon Consultants, Inc. (Terracon) is pleased to submit this Limited Groundwater Assessment report for the above-referenced site. Based upon the previously conducted soil assessment and two rounds of groundwater monitoring identifying select compounds below NR 140, Wisconsin Administrative Code, Enforcement Standards (NR 140 ES), this report recommends that the Wisconsin Department of Natural Resources (WDNR) consider this site for closure.

BACKGROUND

Terracon prepared a Transaction Screen for the above-referenced site dated July 12, 2006. A review of Sanborn Fire Insurance Maps dated 1890 through 1956 indicated that the subject site property was previously occupied by a train roundabout, a building labeled "Combined Locks Paper Co." (1945 and 1956) and "Machine Shop" (1906) and another building labeled "Black Smith" (1906 and 1945). As a result, Terracon performed a Limited Site Assessment (LSA) of the property and prepared an LSA report dated August 10, 2006. The assessment consisted of advancing a push-probe boring near the center of the gravel parking lot (see Figure 1). This was also the estimated location where the machine shop/paper company building and train roundabout adjoined each other. Soil and groundwater samples were collected and analyzed for diesel range organics (DRO), volatile organic compounds (VOC), and Resource Conservation and Recovery Act (RCRA) Metals. RCRA Metals including arsenic, lead, and selenium were detected in groundwater at concentrations exceeding NR 140, Wisconsin Administrative Code, Preventative Action Limits (NR 140 PAL). The detections were subsequently reported to the WDNR. In a telephone conversation on August 24, 2006, the

WDNR required at least one additional round of groundwater monitoring from an NR 141 monitoring well before site closure or a "no action required" status could be achieved.

FIELD ACTIVITIES

Terracon mobilized to the site on September 8, 2006 to install an NR 141 water table monitoring well. The monitoring well was installed in the approximate location of push-probe boring B-1 (see Figure 1) and was advanced using hollow stem auger (HSA) drilling methods. Because samples were already collected during the installation of push-probe boring B-1 (advanced to a depth of 11 feet below grade), samples were not collected from the upper 11 feet during the installation of monitoring well MW-1. Terracon attempted to collect a sample beginning at 12 feet below grade; however, what was believed to be fractured bedrock was not recovered within the split spoon. The probable fractured bedrock was encountered from approximately 11 to 13.5 feet below grade. Refusal (possibly more competent bedrock) was encountered at a depth of approximately 13.5 feet below grade. Terracon installed a 10-slot, 10-foot long screen from approximately 3.5 to 13.5 feet below grade. Filter pack was placed from approximately 3 to 13.5 feet below grade and the monitoring well was sealed with bentonite. The monitoring well was completed with a flush-grade protective cover. A boring log and well construction form are attached.

Terracon returned to the site on September 12, 2006 to develop and sample the monitoring well. The depth to groundwater was measured using an electronic water level indicator that was decontaminated with methanol prior to measurement. Terracon measured the depth to groundwater at approximately 3.87 feet below the top of the casing or approximately 4 feet below grade. The monitoring well was subsequently developed per NR 141, Wisconsin Administrative Code using a disposable bailer. The sample was collected using the same disposable bailer, field-filtered with a 0.45-micron filter cup, and submitted to a Wisconsin-certified laboratory for analysis of arsenic, lead, and selenium. Because soil samples collected during the push-probe assessment did not exceed applicable Residual Contaminant Levels (RCL), cuttings were thin-spread on site. Purge water generated during development was containerized in a 55-gallon drum pending laboratory analysis. A Monitoring Well Development Form, Groundwater Sampling Information Sheet, and laboratory analytical report are attached.

RESULTS AND DISCUSSION

The attached laboratory analytical report indicates that arsenic and selenium, but not lead, continue to be detected at concentrations exceeding respective NR 140 PALs. The NR 140 PAL for arsenic is 1 microgram per liter (µg/L). Arsenic was detected at a concentration of 7.8 µg/L in the groundwater sample collected during the July 26, 2006 push-probe assessment and

was detected at a concentration of 3.0 µg/L in the groundwater sample collected from the monitoring well on September 12, 2006. The NR 140 PAL for selenium is 10 µg/L. Selenium was detected at a concentration of 32 µg/L in the groundwater sample collected during the July 26, 2006 push-probe assessment and was detected at a concentration of 14.7 µg/L in the groundwater sample collected from the monitoring well on September 12, 2006. The NR 140 PAL for lead is 1.5 µg/L. Lead was detected at a concentration of 5.8 µg/L during the July 26, 2006 push-probe assessment but was not detected in the groundwater sample collected from the monitoring well on September 12, 2006.

We discussed the laboratory analytical data with you on September 14, 2006. It is our understanding that the WDNR closure committee, based upon the current and historical analytical data, indicated that closure of the site under NR 726, Wisconsin Administrative Code, is now appropriate. Based upon the limited amount of assessment and reported concentrations, you indicated that a Case Summary and Close Out Request would not be necessary. However, you did indicate that a closure fee of $750, in addition to the following information, would be required in order to obtain closure of the site:

- Acres: Approximately 0.94 acres
- WTM Coordinates: X=657716, Y=424486 (per WDNR GIS Website)
- Zoning: Commercial Core District (CCD)
- Soil Type: The upper approximately 5.5 feet of the subsurface soil includes alternating layers of gravel and top soil, which overlies clay to a depth of approximately 11 feet below grade. Bedrock appears to exist approximately 11 feet below grade (see Terracon's August 10, 2006 LSA Report for a Soil Boring Log).
- Drill/Soil Cutting Disposal Location: Drill cuttings were disposed on the ground surface during the well installation.
- Purge Water Disposal Location: Purge water was temporarily stored in a 55-gallon drum pending receipt of laboratory analytical data. Due to concentrations below NR 140 ESs, purge water will be disposed on the ground surface. Discussed w/ Borski and approved.

On behalf of Ghost-town Fitness Center, Terracon respectfully requests that the WDNR consider this site for closure. A Borehole Abandonment Form prepared by Terracon will be sent separately once monitoring well MW-1 is abandoned. The $750 closure fee will be submitted directly to the WDNR by Ghost-town Fitness Center.

GENERAL COMMENTS

The analysis and opinions expressed in this report are based upon data obtained from the previous assessments and laboratory chemical analyses at the indicated locations or from other information discussed in this report. This report does not reflect variations in subsurface stratigraphy, hydrogeology, and contaminant distribution that may occur across the site. Actual subsurface conditions may vary and may not become evident without further assessment. This report is prepared for the exclusive use of our client for specific application to the project discussed and has been prepared in accordance with generally accepted environmental engineering practices. No warranties, express or implied are intended or made. In the event any changes in the nature or location of suspected sources of contamination as outlined in this report are observed, the conclusions and recommendations contained in this report shall not be valid unless these changes are reviewed and the opinions of this report are modified or verified in writing by Terracon.

Please contact either of the undersigned at (920) 993-9096 if you have questions regarding the information provided in the report.

Sincerely,
Terracon

Phone Log

August 24, 2006

Site Name: Ghost Town Fitness Center
Site ID: pending

Name: Clay Eiting
Phone: 920-766-0149
Initiated By: Borski
Time: 2:45 PM

Subject: NR 141 monitoring well needed

Borski contacted Eiting and stated that based on information provided by Terracon, exceedances of standards exist in groundwater and additional sampling is necessary. (As, Pb and Se > PAL from 1" diam temp well). Borski explained the work needed. Eiting requested Borski contact Terracon and relay this information and request Terracon provide Eiting with a cost estimate. Eiting will decide if he intends to move forward with Terracon or another consultant.

Borski contacted Jason Lowery at Terracon on 8/24/06 at approximately 2:55 PM. Borski informed Lowery of the following required work and possible closure scenarios:
A 2" diameter well should be installed in accordance with NR 141 in the same location as the temp well and sampled for As, Pb & Se. Lowery stated that the initial temp well was a 1" diam, two-foot screen with water at 4 ft but dry clay beneath it and refusal (dolomite chips) at 11 ft. Borski agreed that a 2" diameter, five-foot screen is appropriate in this situation. Lowery will screen from 4-9 ft. Borski stated that one or two weeks may be needed after development to collect enough water for the sample.

If results are below PALs, the case can be created as a NAR (09) after well abandonment. A letter can be issued for $500 "other technical assistance" or the property owner can print off the activity detail report from BRRTS on the Web for free. If results are above PALs, the case will be created as an ERP (02) and a second event required. If the second event from the NR 141 well has results below PALs, a NFA under NR 708 can be issued for $250. If the second event from the NR 141 well has results above PALs, closure under NR 726 can be granted for $750. If closure under NR 726 is required, Borski should review the information previously submitted and determine if it is necessary for a case creation form to be submitted or determine that additional documentation be submitted in a brief update.

Lowery will put together a cost estimate to provide Eiting.

LIMITED SITE ASSESSMENT

GHOST-TOWN FITNESS CENTER
180 FOX SHORES DRIVE
KAUKAUNA, OUTAGAMIE COUNTY, WISCONSIN

TERRACON PROJECT NO. 38067035
AUGUST 11, 2006

1.0 INTRODUCTION

Terracon Consultants, Inc. (Terracon) conducted a Limited Site Assessment (LSA) at the Ghost-town Fitness Center site located at 180 Fox Shores Drive in Kaukauna, Outagamie County, Wisconsin . At your request, Terracon's LSA was undertaken in response to the results of Terracon's Transaction Screen dated July 12, 2006 which identified the following potential environmental concern (PEC):

- Historic Sanborn Fire Insurance Maps depict a train roundabout and buildings labeled "Combined Locks Paper Co.", "Machine Shop", and "Black Smith" at the subject site.

The objective of the LSA was to evaluate the presence of volatile organic compounds (VOC), Resource Conservation and Recovery Act (RCRA) metals, and diesel range organics (DRO) in the on-site soil and groundwater as a result of potential releases associated with the above-referenced PEC. The LSA was completed in general accordance with our proposal dated July 13, 2006.

1.1 Site Description

Site Name	Ghost-town Fitness Center
Site Location/Address	180 Fox Shores Drive, Kaukauna, Wisconsin
General Site Description	A fitness center and gravel parking lot with streets (Bicentennial Court and Fox Shores Drive) to the southwest and northwest, an apartment complex to the southeast, and the Fox River to the northeast.

An aerial photograph is included as Figure 1 of Appendix A.

Re: Limited Groundwater Assessment
Ghost-town Fitness Center
180 Fox Shores Drive
Kaukauna, Wisconsin
WDNR BRRTS #02-45-547911
Terracon Project No. 38067037

Dear Ms. Borski:

On behalf of Ghost-town Fitness Center, Terracon Consultants, Inc. (Terracon) is pleased to submit this Limited Groundwater Assessment report for the above-referenced site. Based upon the previously conducted soil assessment and two rounds of groundwater monitoring identifying select compounds below NR 140, Wisconsin Administrative Code, Enforcement Standards (NR 140 ES), this report recommends that the Wisconsin Department of Natural Resources (WDNR) consider this site for closure.

BACKGROUND

Terracon prepared a Transaction Screen for the above-referenced site dated July 12, 2006. A review of Sanborn Fire Insurance Maps dated 1890 through 1956 indicated that the subject site property was previously occupied by a train roundabout, a building labeled "Combined Locks Paper Co." (1945 and 1956) and "Machine Shop" (1906) and another building labeled "Black Smith" (1906 and 1945). As a result, Terracon performed a Limited Site Assessment (LSA) of the property and prepared an LSA report dated August 10, 2006. The assessment consisted of advancing a push-probe boring near the center of the gravel parking lot (see Figure 1). This was also the estimated location where the machine shop/paper company building and train roundabout adjoined each other. Soil and groundwater samples were collected and analyzed for diesel range organics (DRO), volatile organic compounds (VOC), and Resource Conservation and Recovery Act (RCRA) Metals. RCRA Metals including arsenic, lead, and selenium were detected in groundwater at concentrations exceeding NR 140, Wisconsin Administrative Code, Preventative Action Limits (NR 140 PAL). The detections were subsequently reported to the WDNR. In a telephone conversation on August 24, 2006, the

WDNR required at least one additional round of groundwater monitoring from an NR 141 monitoring well before site closure or a "no action required" status could be achieved.

FIELD ACTIVITIES

Terracon mobilized to the site on September 8, 2006 to install an NR 141 water table monitoring well. The monitoring well was installed in the approximate location of push-probe boring B-1 (see Figure 1) and was advanced using hollow stem auger (HSA) drilling methods. Because samples were already collected during the installation of push-probe boring B-1 (advanced to a depth of 11 feet below grade), samples were not collected from the upper 11 feet during the installation of monitoring well MW-1. Terracon attempted to collect a sample beginning at 12 feet below grade; however, what was believed to be fractured bedrock was not recovered within the split spoon. The probable fractured bedrock was encountered from approximately 11 to 13.5 feet below grade. Refusal (possibly more competent bedrock) was encountered at a depth of approximately 13.5 feet below grade. Terracon installed a 10-slot, 10-foot long screen from approximately 3.5 to 13.5 feet below grade. Filter pack was placed from approximately 3 to 13.5 feet below grade and the monitoring well was sealed with bentonite. The monitoring well was completed with a flush-grade protective cover. A boring log and well construction form are attached.

Terracon returned to the site on September 12, 2006 to develop and sample the monitoring well. The depth to groundwater was measured using an electronic water level indicator that was decontaminated with methanol prior to measurement. Terracon measured the depth to groundwater at approximately 3.87 feet below the top of the casing or approximately 4 feet below grade. The monitoring well was subsequently developed per NR 141, Wisconsin Administrative Code using a disposable bailer. The sample was collected using the same disposable bailer, field-filtered with a 0.45-micron filter cup, and submitted to a Wisconsin-certified laboratory for analysis of arsenic, lead, and selenium. Because soil samples collected during the push-probe assessment did not exceed applicable Residual Contaminant Levels (RCL), cuttings were thin-spread on site. Purge water generated during development was containerized in a 55-gallon drum pending laboratory analysis. A Monitoring Well Development Form, Groundwater Sampling Information Sheet, and laboratory analytical report are attached.

RESULTS AND DISCUSSION

The attached laboratory analytical report indicates that arsenic and selenium, but not lead, continue to be detected at concentrations exceeding respective NR 140 PALs. The NR 140 PAL for arsenic is 1 microgram per liter (µg/L). Arsenic was detected at a concentration of 7.8 µg/L in the groundwater sample collected during the July 26, 2006 push-probe assessment and

was detected at a concentration of 3.0 µg/L in the groundwater sample collected from the monitoring well on September 12, 2006. The NR 140 PAL for selenium is 10 µg/L. Selenium was detected at a concentration of 32 µg/L in the groundwater sample collected during the July 26, 2006 push-probe assessment and was detected at a concentration of 14.7 µg/L in the groundwater sample collected from the monitoring well on September 12, 2006. The NR 140 PAL for lead is 1.5 µg/L. Lead was detected at a concentration of 5.8 µg/L during the July 26, 2006 push-probe assessment but was not detected in the groundwater sample collected from the monitoring well on September 12, 2006.

We discussed the laboratory analytical data with you on September 14, 2006. It is our understanding that the WDNR closure committee, based upon the current and historical analytical data, indicated that closure of the site under NR 726, Wisconsin Administrative Code, is now appropriate. Based upon the limited amount of assessment and reported concentrations, you indicated that a Case Summary and Close Out Request would not be necessary. However, you did indicate that a closure fee of $750, in addition to the following information, would be required in order to obtain closure of the site:

- Acres: Approximately 0.94 acres
- WTM Coordinates: X=657716, Y=424486 (per WDNR GIS Website)
- Zoning: Commercial Core District (CCD)
- Soil Type: The upper approximately 5.5 feet of the subsurface soil includes alternating layers of gravel and top soil, which overlies clay to a depth of approximately 11 feet below grade. Bedrock appears to exist approximately 11 feet below grade (see Terracon's August 10, 2006 LSA Report for a Soil Boring Log).
- Drill/Soil Cutting Disposal Location: Drill cuttings were disposed on the ground surface during the well installation.
- Purge Water Disposal Location: Purge water was temporarily stored in a 55-gallon drum pending receipt of laboratory analytical data. Due to concentrations below NR 140 ESs, purge water will be disposed on the ground surface. Discussed w/ Borski and approved.

On behalf of Ghost-town Fitness Center, Terracon respectfully requests that the WDNR consider this site for closure. A Borehole Abandonment Form prepared by Terracon will be sent separately once monitoring well MW-1 is abandoned. The $750 closure fee will be submitted directly to the WDNR by Ghost-town Fitness Center.

GENERAL COMMENTS

The analysis and opinions expressed in this report are based upon data obtained from the previous assessments and laboratory chemical analyses at the indicated locations or from other information discussed in this report. This report does not reflect variations in subsurface stratigraphy, hydrogeology, and contaminant distribution that may occur across the site. Actual subsurface conditions may vary and may not become evident without further assessment. This report is prepared for the exclusive use of our client for specific application to the project discussed and has been prepared in accordance with generally accepted environmental engineering practices. No warranties, express or implied are intended or made. In the event any changes in the nature or location of suspected sources of contamination as outlined in this report are observed, the conclusions and recommendations contained in this report shall not be valid unless these changes are reviewed and the opinions of this report are modified or verified in writing by Terracon.

Please contact either of the undersigned at (920) 993-9096 if you have questions regarding the information provided in the report.

Sincerely,
Terracon

Based on current backlog, it will likely be approximately two weeks for the closure committee to route, review and approve the closure once they receive the request. It is then forwarded back to me to send you a letter. I can typically get the letter out within a week but will call you with the answer the day that I receive the packet back on my desk.

I will include a note with the request that your financing is pending closure of the case. That information may move it faster.

When the request and fee are received, I will route to the committee ASAP for their review. "Absolutely sure that it is OK to abandon the monitoring well" means waiting for the entire closure committee to review the request for closure. As stated in the past, I've discussed the details of this case with Keld Lauridsen and he is in support of no additional monitoring. I do not anticipate any disagreement from the rest of the committee with my and Keld's support of abandonment. Regardless, I will call you with the closure committee decision once it is final.

Subject: Closure Fee

Clay,

Wisconsin Administrative Code, NR 749.04, requires a fee of $750 for Department review of a request for closure under chapter NR 726. Please submit a check made payable to "Department of Natural Resources" and send to:

Jennifer Borski, WDNR
625 E Cty Rd Y, STE. 700
Oshkosh, WI 54901-9731

Please reference BRRTS # 02-45-547911 on the check to assure proper tracking of the payment.

A link to NR 749 is included for your reference, if interested:

OK to dispose PAL purge water on site. 4B 9/19/06

A closure form does not need to be submitted but the following should be included in the request for closure along with the soil and groundwater data summaries and basic site map showing property boundaries with respect to roads/waterways, etc, land use cover (e.g. structure, grass, gravel, etc), boring/well locations:

- acres
- WTM coordinates
- zoning
- soil type
- drill/soil cutting disposal location
- purge water disposal location

The request should also discuss the reason for the boring/well locations as identified in the Phase I.

create ERP
- PAL gw disposal method ?

Jason,

My understanding from your message is that the NR 141 replacement well revealed no PAL exceedance for lead but arsenic at 3 ppb (PAL = 1 ppb) and selenium at 14.7 ppb (PAL = 10 ppb). These concentrations are similar to the original concentrations detected in groundwater from the 1" diam temp well of arsenic = 7.8 ppb (J flag) and selenium = 32 ppb.

First of all, the NR 141 results should be reviewed to confirm that they are in fact PAL exceedances in accordance with NR 140.14, WAC. I talked with the closure committee regarding this situation to confirm the owner has two options under the NR 700 series if they are PAL exceedances under NR 140.14:

1. DNR will create a case (assign an ERP BRRTS #) and owner needs to request closure under NR 726 by submitting the necessary documentation along with a fee of $750 and receive closure with a PAL exemption for arsenic and selenium once the well is abandoned (no closure form necessary but acres and some other details need to be included in a cover letter & site map).

2. DNR will continue to hold this case in "pending" and owner needs to resample the NR 141 well for arsenic and selenium. If PAL exceedances remain, DNR will create an ERP case and closure should be requested as discussed in #1 above. If PAL exceedances are no longer present, DNR will create a NAR case ("no action required") and nothing further is needed aside from well abandonment.

Let me know if you have further questions.

State of Wisconsin \ DEPARTMENT OF NATURAL RESOURCES

Phone Log

August 24, 2006

Site Name: Ghost Town Fitness Center
Site ID: pending

Name: Clay Eiting
Phone: 920-766-0149
Initiated By: Borski
Time: 2:45 PM

Subject: NR 141 monitoring well needed

Borski contacted Eiting and stated that based on information provided by Terracon, exceedances of standards exist in groundwater and additional sampling is necessary. (As, Pb and Se > PAL from 1" diam temp well). Borski explained the work needed. Eiting requested Borski contact Terracon and relay this information and request Terracon provide Eiting with a cost estimate. Eiting will decide if he intends to move forward with Terracon or another consultant.

Borski contacted Jason Lowery at Terracon on 8/24/06 at approximately 2:55 PM. Borski informed Lowery of the following required work and possible closure scenarios:
A 2" diameter well should be installed in accordance with NR 141 in the same location as the temp well and sampled for As, Pb & Se. Lowery stated that the initial temp well was a 1" diam, two-foot screen with water at 4 ft but dry clay beneath it and refusal (dolomite chips) at 11 ft. Borski agreed that a 2" diameter, five-foot screen is appropriate in this situation. Lowery will screen from 4-9 ft. Borski stated that one or two weeks may be needed after development to collect enough water for the sample.

If results are below PALs, the case can be created as a NAR (09) after well abandonment. A letter can be issued for $500 "other technical assistance" or the property owner can print off the activity detail report from BRRTS on the Web for free. If results are above PALs, the case will be created as an ERP (02) and a second event required. If the second event from the NR 141 well has results below PALs, a NFA under NR 708 can be issued for $250. If the second event from the NR 141 well has results above PALs, closure under NR 726 can be granted for $750. If closure under NR 726 is required, Borski should review the information previously submitted and determine if it is necessary for a case creation form to be submitted or determine that additional documentation be submitted in a brief update.

Lowery will put together a cost estimate to provide Eiting.

To: Danelski, Denise D; Jones, Casey L.
Subject: RE: Ghost Town Fitness Center - Pending

Updated information - I forgot we cannot issue a NFA under NR 708 if groundwater is above a PAL. It must be a NR 726 closure then... I underlined the additions to the original message below.

From: Borski, Jennifer
Sent: Thursday, August 24, 2006 11:58 AM
To: Danelski, Denise D; Jones, Casey L.
Subject: Ghost Town Fitness Center - Pending

Denise and Casey,

I took a look at the documentation provided to us for the Ghost Town Fitness Center (pending case). They have three PAL exceedances for arsenic, lead and selenium but no apparent issue in the one soil sample collected. The PAL exceedances are likely due to the fact that the water sample was collected from a 1" diam temp well and was turbid (high particle count). Unfortunately, we need them to follow-up to determine if there are actually exceedances of the PALs.

I am going to request the property owner install a NR 141 well and resample for these metals to determine if PAL exceedances actually exist. This is consistent with how we've handled other PAL exceedances reported from temp wells. If there is no confirmed PAL exceedance, it will become a NAR as no release could be confirmed. If there is a release (PAL exceedance), they will need to do more investigation into the source for the PAL exceedances (since there does not appear to be a soil issue) and we'll create this as an ERP. I anticipate that if an ERP is created, we can close under NR 726 once they collect two rounds from the NR 141 well to confirm a PAL exceedance with a stable trend.

This may be pending for more than two months and you may get results back after I'm on maternity leave. If that is the case, I hope this e-mail will help decide how to address the NR 141 well data. You can also reference the APEX Real Estate NAR 09-45-544973 (8/16/06) and the Sulpaco West (former) - Parking Lot (02 yet to be assigned) for guidance on how to deal with the results if needed after I'm gone.

I spoke with Jason Lowry with Terracon this morning. Terracon was hired by the bank that is looking to loan the son, Clay Eiting, money to purchase the property from his father, Jeff Eiting. Unfortunately, Terracon advised Clay that the Department would likely not require anything further. I have yet to reach Clay but will document that conversation as well. Hopefully, Clay will be willing to install the NR 141 well voluntarily while the case is "pending". Otherwise, we will need to issue Jeff an RP letter based on the reported PAL exceedances, create the 02 and require the NR 141 well & sampling. If we are forced into this route, I believe we can issue a NFA under ch. NR 708 if the NR 141 well shows no PAL exceedance but will have to close under NR 726 if there is a confirmed PAL exceedance.

Fax Notification For Hazardous Substance Discharge (Non-Emergency Only)

Emergency Discharges / Spills should be reported via the 24-Hour Hotline: 1-800-943-0003

Notice: **Hazardous substance discharges must be reported immediately** according to the "Spills Law", s. 292.11 Wis. Stats., Section NR 706.05(1)(b), Wis. Adm. Code, requires that hazardous substance discharges are to be reported by one of three methods: telephoning the Department (toll free Spill Hotline number above), telefaxing a report to the Department or visiting a Department office in person. If you choose to notify the Department by telefax, you should use this form to be sure that all necessary information is included. However use of this form is not mandatory. Under s. 292.99, Wis. Stats., the penalty for violating the reporting requirements of ch. 292 Wis. Stats., shall be no less than $10 nor more than $5000 for each violation. Each day of continued violation is a separate offense. It is not the Department's intention to use any personally identifiable information from this form for any purpose other than program administration. However, information submitted on this form may also be made available to requesters under Wisconsin's Open Records Law (ss. 19.31 – 19.39, Wis. Stats.). Confirmatory laboratory data should be included with this form, to assist the DNR in processing this Hazardous Substance Release Notification.

Complete this form. **TYPE or PRINT LEGIBLY.** FAX it to the appropriate DNR region (see next page) **IMMEDIATELY** upon discovery of a potential release from **(check one)**:

- ☐ Underground Petroleum Storage Tank System
- ☐ Aboveground Petroleum Storage Tank System
- ☐ Dry Cleaner Facility (DERP eligibility based on: ☐ Facility owner/operator ☐ Property owner of licensed facility)
- ☐ Other - Describe:

TO DNR, ATTN: **R & R Program Assistant**	(Area Code) FAX Number
	(920) 766-9338

1. Discharge reported by:

Name	Firm	Date FAXed to DNR
Clay J Eiting	Ghost-Town Fitness Center	8/22/06
Mailing Address		**(Area Code) Phone Number**
180 Fox Shores Dr Kaukauna WI 54130		(920) 766-0149

2. Site Information

Name of site at which discharge occurred. Include local name of site/business, not responsible party name, unless a residence / vacant property

Ghost-town Fitness Center

Location: Include street address, not PO Box. If no street address, describe as precisely as possible, i.e., 1/4 mile NW of CTHs 60 & 123 on E side of CTH 60

180 Fox Shores Dr

Municipality (City, Village, Township) Specify municipality in which the site is located, not mailing address/city

Kaukauna

County:	Legal Description:
Outagamie	____ 1/4, NW 1/4, Section 22, Tn 21N, Range 18 (E)/ W (circle one)

3. Responsible Party (RP) and/or RP Representative

☒ Responsible Party Name: Business or owner name that is responsible for cleanup. If more than one, list all Attach additional pages as necessary

Jeff Eiting

☑ Reported in compliance with s. 292.11(2), Wis. Stats., by a local government exempt from liability under s. 292.11(9)(e), Wis. Stats. For more information see http://dnr.wi.gov/org/aw/rr/liability/muni_1.html

Contact Person Name (if different)			Phone Number
Clay Eiting			(920) 766-0149
Mailing Address	**City**	**State**	**ZIP Code**

Department of Natural Resources

Fax Notification For Hazardous Substance Discharge (Non-Emergency Only)

4. Hazardous Substance Impact Information

Identify hazardous substance ~~discharged~~ detected (check all that apply):

METALS
- [x] Arsenic
- [x] Chromium
- [x] Lead
- [x] Mercury
- [x] Metals (specify): _____

SOLVENTS
- [ ] Solvent-Chlorinated
- [ ] Solvent-Non Chlorinated
- [ ] PERC
- [ ] VOC's

INDUSTRIAL CHEMICALS
- [ ] Ammonia
- [ ] Cyanide
- [ ] Paint
- [ ] PCB's
- [ ] VOC's
- [ ] Fertilizers
- [ ] Pesticide/Herbicide/Insecticide(s)
- [ ] Leachate
- [ ] RCRA Hazardous Waste

PETROLEUM
- [x] Diesel/Fuel Oil (DRO)
- [ ] Engine Oil/Waste Oil
- [ ] Mineral/Transmission/Hydraulic Oil
- [ ] Gasoline (Pb/Non-Pb/Unknown)
- [ ] Jet Fuel/Kerosene
- [ ] MTBE
- [ ] VOC's
- [ ] PAH's/SVOC
- [ ] Petroleum-Unknown Type
- [ ] Unknown
- [ ] Other (specify):_____

Impacts to the environment (enter "K" for known/confirmed or "P" for potential for all that apply)

___ Air Contamination	___ Contamination in Right of Way	___ Sanitary Sewer Contamination
___ Co-contamination	___ Direct Contact	K Soil ~~Contamination~~ detection
___ Concrete/Asphalt	___ Expanding Plume	___ Storm Sewer Contamination
___ Contained/Recovered	___ Fire Explosion Threat	___ Surface Water Contamination
___ Contamination Within 1 Meter of Bedrock	___ Free Product	___ Within 100 ft of Private Well
___ Contaminated Private Well	K Groundwater ~~Contamination~~ detection	___ Within 1000 ft of Public Well
___ Contaminated Public Well	___ Off-Site Contamination	
___ Contamination in Fractured Bedrock	___ Other	

Contamination was discovered as a result of:

[ ] Tank closure assessment	[x] Site assessment	Other – Describe:
Date	Date	Date

Lab results:
- [ ] Lab results will be faxed upon receipt
- [x] Lab results are attached

Additional Comments: Include a brief description of immediate actions taken to halt the release and contain or cleanup hazardous substances that have been discharged.

Concentrate doesn't appear for further action!

FAX numbers to report non-emergency releases in DNR's five regions are as follows:

Northeast Region (920-662-5197); Attention - RR Program Assistant:
Brown, Calumet, Door, Fond du Lac ***(except City of Waupun - see South Central Region)***, Green Lake, Kewaunee, Manitowoc, Marinette, Marquette, Menominee, Oconto, Outagamie, Shawano, Waupaca, Waushara, Winnebago counties

Northern Region (715-365-8932); Attention - RR Program Assistant:
Ashland, Barron, Bayfield, Burnett, Douglas, Forest, Florence, Iron, Langlade, Lincoln, Oneida, Polk, Price, Rusk, Sawyer, Taylor, Vilas, Washburn counties

South Central Region (608-275-3338); Attention - RR Program Assistant:
Columbia, Dane, Dodge, Fond du Lac ***(City of Waupun only)***, Grant, Green, Iowa, Jefferson, Lafayette, Richland, Rock, Sauk counties

Southeast Region (414-263-8483); Attention - RR Program Assistant:
Kenosha, Milwaukee, Ozaukee, Racine, Sheboygan, Walworth, Washington, Waukesha counties

West Central Region (715-839-6076); Attention – RR Program Assistant:
Adams, Buffalo, Chippewa, Clark, Crawford, Dunn, Eau Claire, Jackson, Juneau, LaCrosse, Marathon, Monroe, Pepin

TERRACON GROUND WATER SAMPLING INFORMATION SHEET

PROJECT NAME: Ghost-town Fitness Center		PROJECT NO.
PROJECT LOCATION: Kaukauna, WI		
SAMPLE POINT: B-1	SAMPLE POINT DESCRIPTION: Center of parking lot	
CASING DIAMETER: 1"		
WELL DEPTH: 11 feet		
DATE: 7/26/06	TIME: 0915 AM/PM	DEPTH TO GROUND WATER (FT): ≈5

CALCULATION: N/A

SAMPLING METHOD: VOC & DRO - Stainless steel screen (2-foot long) & HDPE tubing & check valve
RCRA metals - 5" PVC screen & disposable bailer - 5-foot long

DATE	TIME (AM/PM)	GALLONS REMOVED	COMMENTS
7/26/06	0910	0.25?	Started pursing water
	0912		Started sampling
7/26/06	0945		Collected sample (finished)

DISSOLVED OXYGEN:	FERROUS IRON:	NITRATE
----	----	----

pH:	ORP:	TEMP:	SPECIFIC CONDUCTANCE (uS/cm) x1000
----	----	----	----

SAMPLE APPEARANCE: VERY TURBID (TURBID) SLIGHTLY TURBID CLEAR

ODOR: YES (NO) NOT NOTED

ANALYSES: VOC, DRO, RCRA Metals

CLEANING PERFORMED IN FIELD: METHANOL AND DISPOSABLE GLOVES JBL

COMMENTS:
Filtered sample for RCRA Metals - filters kept clogging hence the long sampling time above

SAMPLED BY: JBL DATE: 7/26/06

WI DNR RECEIVED AUG 23 2006 NER WASTE/RR

Fax Notification For Hazardous Substance Discharge (Non-Emergency Only)

Emergency Discharges / Spills should be reported via the 24-Hour Hotline: 1-800-943-0003

Notice: Hazardous substance discharges must be reported immediately according to the "Spills Law", s. 292.11 Wis. Stats., Section NR 706.05(1)(b), Wis. Adm. Code, requires that hazardous substance discharges are to be reported by one of three methods: telephoning the Department (toll free Spill Hotline number above), telefaxing a report to the Department or visiting a Department office in person. If you choose to notify the Department by telefax, you should use this form to be sure that all necessary information is included. However use of this form is not mandatory. Under s. 292.99, Wis. Stats., the penalty for violating the reporting requirements of ch. 292 Wis. Stats., shall be no less than $10 nor more than $5000 for each violation. Each day of continued violation is a separate offense. It is not the Department's intention to use any personally identifiable information from this form for any purpose other than program administration. However, information submitted on this form may also be made available to requesters under Wisconsin's Open Records Law (ss. 19.31 – 19.39, Wis. Stats.).
Confirmatory laboratory data should be included with this form, to assist the DNR in processing this Hazardous Substance Release Notification.

Complete this form. **TYPE or PRINT LEGIBLY.** FAX it to the appropriate DNR region (see next page) **IMMEDIATELY** upon discovery of a potential release from **(check one)**:

- ☐ Underground Petroleum Storage Tank System
- ☐ Aboveground Petroleum Storage Tank System
- ☐ Dry Cleaner Facility (DERP eligibility based on: ☐ Facility owner/operator ☐ Property owner of licensed facility)
- ☐ Other - Describe:

4. Hazardous Substance Impact Information

Identify hazardous substance ~~discharged~~ detected (check all that apply):

METALS
- [x] Arsenic
- [x] Chromium
- [x] Lead
- [x] Mercury
- [x] Metals (specify): _____

INDUSTRIAL CHEMICALS
- [ ] Ammonia
- [ ] Cyanide
- [ ] Paint
- [ ] PCB's
- [ ] VOC's
- [ ] Fertilizers
- [ ] Pesticide/Herbicide/Insecticide(s)
- [ ] Leachate
- [ ] RCRA Hazardous Waste

PETROLEUM
- [x] Diesel/Fuel Oil (DRO)
- [ ] Engine Oil/Waste Oil
- [ ] Mineral/Transmission/Hydraulic Oil
- [ ] Gasoline (Pb/Non-Pb/Unknown)
- [ ] Jet Fuel/Kerosene
- [ ] MTBE
- [ ] VOC's
- [ ] PAH's/SVOC
- [ ] Petroleum-Unknown Type

SOLVENTS
- [ ] Solvent-Chlorinated
- [ ] Solvent-Non Chlorinated
- [ ] PERC
- [ ] VOC's

- [ ] Unknown
- [ ] Other (specify):_____

Impacts to the environment (enter "K" for known/confirmed or "P" for potential for all that apply)

- ___ Air Contamination
- ___ Co-contamination
- ___ Concrete/Asphalt
- ___ Contained/Recovered
- ___ Contamination Within 1 Meter of Bedrock
- ___ Contaminated Private Well
- ___ Contaminated Public Well
- ___ Contamination in Fractured Bedrock
- ___ Contamination in Right of Way
- ___ Direct Contact
- ___ Expanding Plume
- ___ Fire Explosion Threat
- ___ Free Product
- P Groundwater ~~Contamination~~ detection
- ___ Off-Site Contamination
- ___ Other
- ___ Sanitary Sewer Contamination
- K Soil ~~Contamination~~ detection
- ___ Storm Sewer Contamination
- ___ Surface Water Contamination
- ___ Within 100 ft of Private Well
- ___ Within 1000 ft of Public Well

Contamination was discovered as a result of:

- [ ] Tank closure assessment — Date
- [x] Site assessment — Date
- Other – Describe: — Date

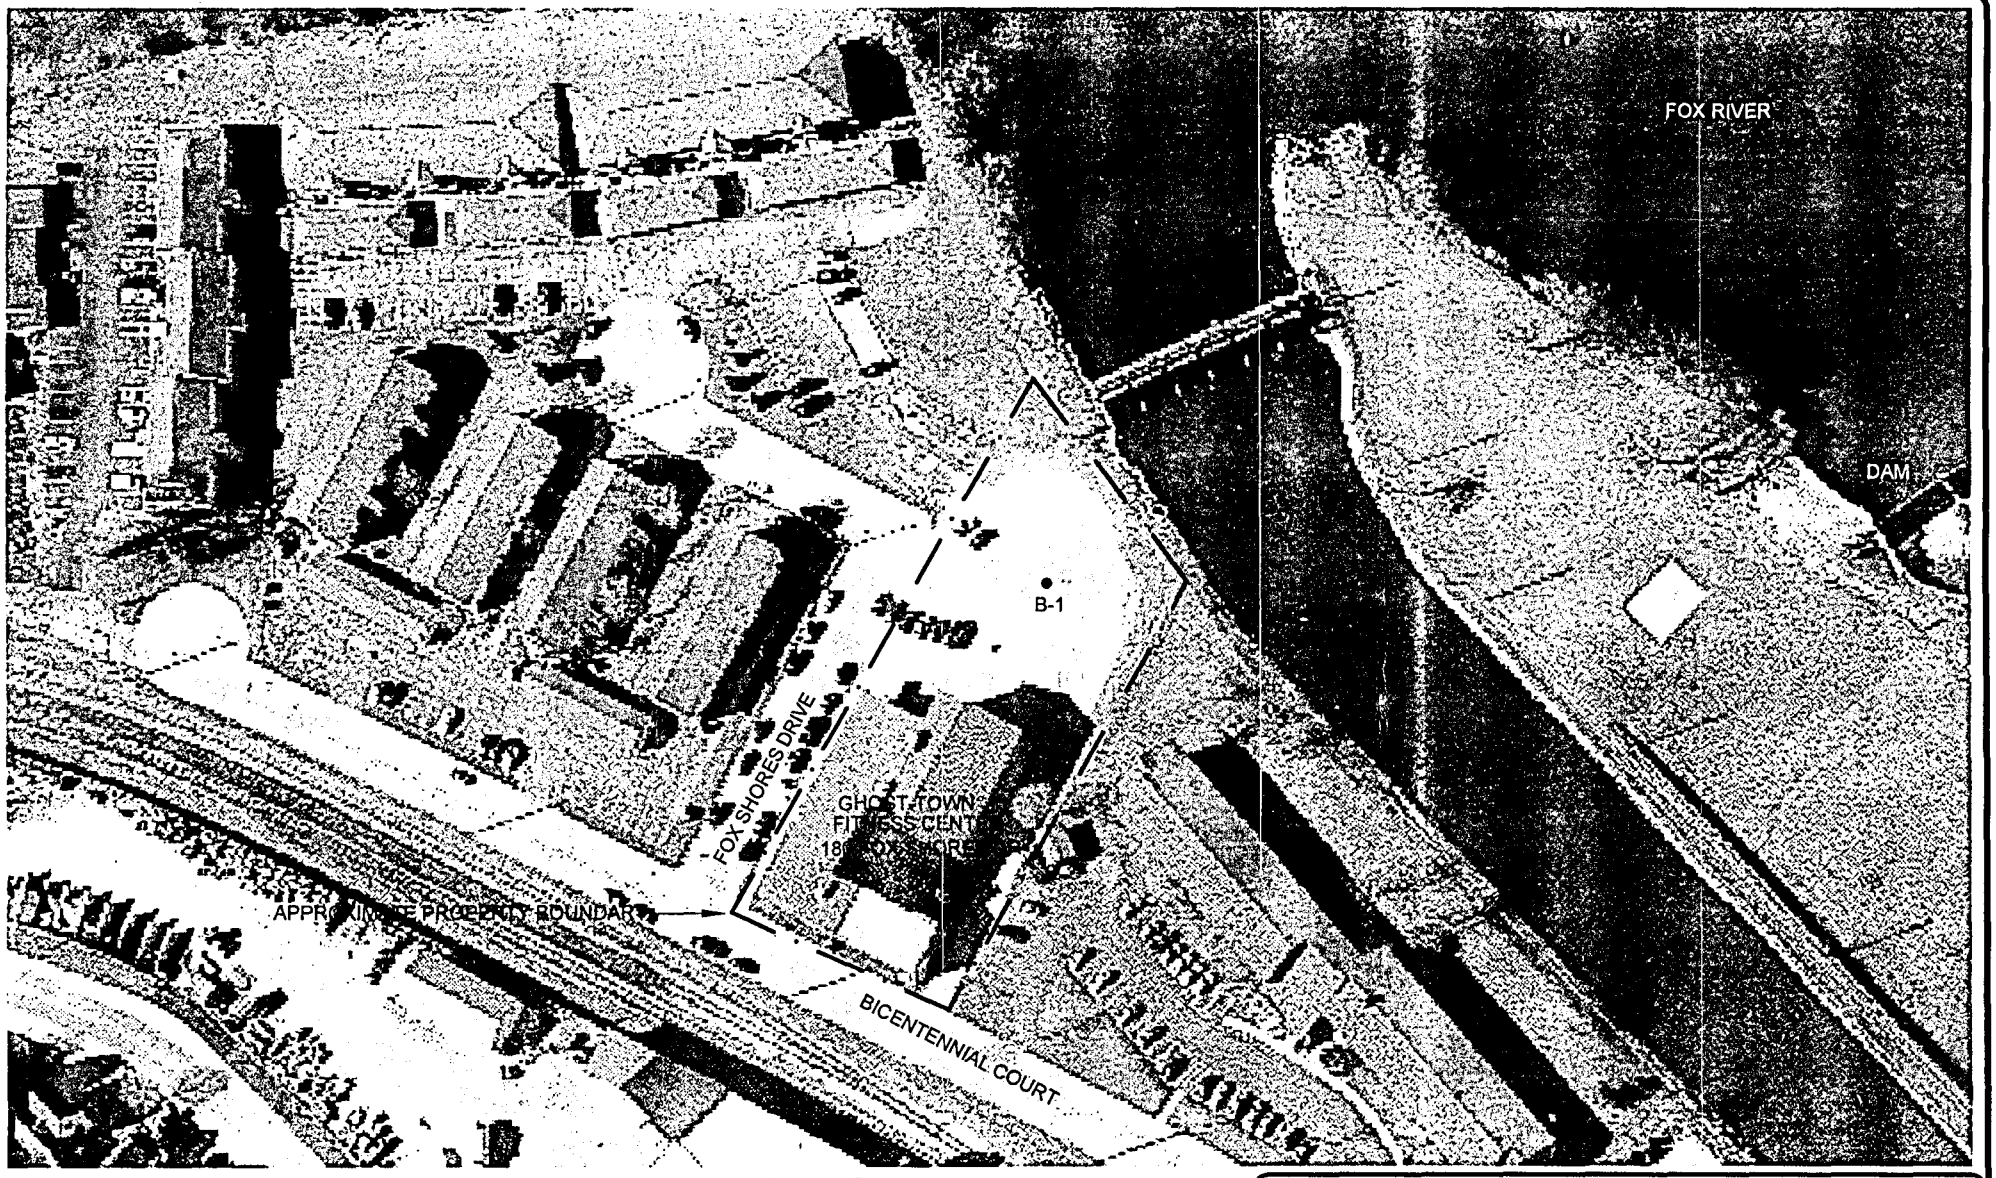
Lab results:

- [ ] Lab results will be faxed upon receipt
- [x] Lab results are attached

Additional Comments: Include a brief description of immediate actions taken to halt the release and contain or cleanup hazardous substances that have been discharged.

Concentrate doesn't appear for further action!

FAX numbers to report non-emergency releases in DNR's five regions are as follows:



Northeast Region (920-662-5197); Attention - RR Program Assistant:
Brown, Calumet, Door, Fond du Lac ***(except City of Waupun - see South Central Region)***, Green Lake, Kewaunee, Manitowoc, Marinette, Marquette, Menominee, Oconto, Outagamie, Shawano, Waupaca, Waushara, Winnebago counties

Northern Region (715-365-8932); Attention - RR Program Assistant:
Ashland, Barron, Bayfield, Burnett, Douglas, Forest, Florence, Iron, Langlade, Lincoln, Oneida, Polk, Price, Rusk, Sawyer, Taylor, Vilas, Washburn counties

South Central Region (608-275-3338); Attention - RR Program Assistant:
Columbia, Dane, Dodge, Fond du Lac ***(City of Waupun only)***, Grant, Green, Iowa, Jefferson, Lafayette, Richland, Rock, Sauk counties

Southeast Region (414-263-8483); Attention - RR Program Assistant:
Kenosha, Milwaukee, Ozaukee, Racine, Sheboygan, Walworth, Washington, Waukesha counties

West Central Region (715-839-6076); Attention – RR Program Assistant:
Adams, Buffalo, Chippewa, Clark, Crawford, Dunn, Eau Claire, Jackson, Juneau, LaCrosse, Marathon, Monroe, Pepin, Pierce, Portage, St. Croix, Trempealeau, Vernon, Wood counties

AUGUST 11, 2006

1.0 INTRODUCTION

Terracon Consultants, Inc. (Terracon) conducted a Limited Site Assessment (LSA) at the Ghost-town Fitness Center site located at 180 Fox Shores Drive in Kaukauna, Outagamie County, Wisconsin . At your request, Terracon's LSA was undertaken in response to the results of Terracon's Transaction Screen dated July 12, 2006 which identified the following potential environmental concern (PEC):

- Historic Sanborn Fire Insurance Maps depict a train roundabout and buildings labeled "Combined Locks Paper Co.", "Machine Shop", and "Black Smith" at the subject site.

The objective of the LSA was to evaluate the presence of volatile organic compounds (VOC), Resource Conservation and Recovery Act (RCRA) metals, and diesel range organics (DRO) in the on-site soil and groundwater as a result of potential releases associated with the above-referenced PEC. The LSA was completed in general accordance with our proposal dated July 13, 2006.

1.1 Site Description

Site Name	Ghost-town Fitness Center
Site Location/Address	180 Fox Shores Drive, Kaukauna, Wisconsin
General Site Description	A fitness center and gravel parking lot with streets (Bicentennial Court and Fox Shores Drive) to the southwest and northwest, an apartment complex to the southeast, and the Fox River to the northeast.

An aerial photograph is included as Figure 1 of Appendix A.

Well / Drillhole / Borehole Abandonment

Form 3300-005 (R 10/03)

Notice: Completion of this report is required by chs. 160, 281, 283, 289, 291-293, 295, and 299, Wis. Stats., and ch. NR 141, Wis. Adm. Code. In accordance with chs. 281, 289, 291-293, 295, and 299, Wis. Stats., failure to file this form may result in a forfeiture of between $10-25,000, or imprisonment for up to one year, depending on the program and conduct involved. Personally identifiable information on this form is not intended to be used for any other purpose. Return form to the appropriate DNR office and bureau. See instructions on reverse for more information.

1. General Information

WI Unique Well No.: — — — — — —
DNR Well ID No.:
County: Outagamie
Common Well Name: B-1
Gov't Lot # (if applicable):
¼¼: ¼: NW
Section: 22
Township: 21 N
Range: 18 ☒ E ☐ W
Grid Location: Feet ☐ N ☐ S Feet ☐ E ☐ W ☐ Local Grid Origin ☐ (estimated) OR ☐ Well Location
Latitude: DEG MIN SEC N
Longitude: DEG MIN SEC W
Reason For Abandonment: Finished sampling
WI Unique Well No. of Replacement We: — — — — — —

2. Facility / Owner Information

Facility Name: Ghost-town Fitness Center
Facility ID:
License/Permit/Monitoring No:
City, Village or Town:
Street Address of Well: 180 Fox Shores Drive
Present Well Owner:
Original Well Owner:
Street Address or Route of Owner:
City: Kaukauna
State: WI
ZIP Code: 54130

3. Well / Drillhole / Borehole Information

☐ Monitoring Well
☐ Water Well
☒ Borehole / Drillhole
Original Construction Date: 7/26/06
If a Well Construction Report is available, please attach.

Construction Type:
☐ Drilled ☐ Driven (Sandpoint) ☐ Dug
☒ Other (specify): push-probe

Formation Type:
☒ Unconsolidated Formation ☐ Bedrock

Total Well Depth From Groundsurface (ft.): 11
Casing Diameter (in.): 1
Lower Drillhole Diameter (in.): 2
Casing Depth (ft.):

Was well annular space grouted? ☐ Yes ☒ No ☐ Unknown
If yes, to what depth (feet)?
Depth to Water (feet):

4. Pump, Liner, Screen, Casing & Sealing Material

Pump and piping removed?	☐ Yes	☐ No	☐ N/A
Liner(s) removed?	☐ Yes	☐ No	☐ N/A
Screen removed?	☐ Yes	☐ No	☐ N/A
Casing left in place?	☐ Yes	☐ No	☐ N/A
Was casing cut off below surface?	☐ Yes	☐ No	☐ N/A
Did sealing material rise to surface?	☐ Yes	☐ No	☐ N/A
Did material settle after 24 hours?	☐ Yes	☐ No	☐ N/A
If yes, was hole retopped?	☐ Yes	☐ No	☐ N/A
If bentonite chips were used, were they hydrated with water from a known safe source?	☐ Yes	☐ No	☐ N/A

Required Method of Placing Sealing Material
☐ Conductor Pipe-Gravity ☐ Conductor Pipe-Pumped
☒ Screened & Poured (Bentonite Chips) ☐ Other (Explain):

Sealing Materials
☐ Neat Cement Grout ☐ Clay-Sand Slurry (11 lb./gal. wt.)
☐ Sand-Cement (Concrete) Grout ☐ Bentonite-Sand Slurry " "
☐ Concrete ☒ Bentonite Chips

For Monitoring Wells and Monitoring Well Boreholes Only:
☐ Bentonite Chips ☐ Bentonite - Cement Grout
☐ Granular Bentonite ☐ Bentonite - Sand Slurry

5. Material Used To Fill Well / Drillhole

Material	From (ft.)	To (ft.)	No. Yards, Sacks Sealant or Volume (circle one)	Mix Ratio or Mud Weight
Bentonite - 3/8" Chips	Surface	2	1/20	
Sand	2	11	1/4

TERRACON GROUND WATER SAMPLING INFORMATION SHEET

PROJECT NAME: Ghost-Town Fitness Center	PROJECT NO.
PROJECT LOCATION: Kenosha, WI	
SAMPLE POINT: B-1	SAMPLE POINT DESCRIPTION: Center of parking lot
CASING DIAMETER: 1"	
WELL DEPTH: 11 feet	

DATE: 7/26/06	TIME: 0915 AM /PM	DEPTH TO GROUND WATER (FT): ≈5

CALCULATION: N/A

SAMPLING METHOD: VOC & DRO - Stainless steel screen (2-foot long) & HDPE tubing & check valve
RCRA Metals - 5' PVC screen & disposable bailer - 5-foot long

DATE	TIME (AM/PM)	GALLONS REMOVED	COMMENTS
7/26/06	0910	0.25?	Started pursing water
	0912		Started sampling
7/26/06	0945		Collected sample (finished)

DISSOLVED OXYGEN:	FERROUS IRON:	NITRATE
----	----	--------

pH:	ORP:	TEMP:	SPECIFIC CONDUCTANCE (uS/cm) x1000
-------	----	--------	----

SAMPLE APPEARANCE: VERY TURBID (TURBID) SLIGHTLY TURBID CLEAR

ODOR: YES (NO) NOT NOTED

ANALYSES: VOC, DRO, RCRA Metals

CLEANING PERFORMED IN FIELD: *METHANOL AND DISPOSABLE GLOVES* *INITIAL TO VERIFY OR NOTE OTHER CLEANING METHOD PERFORMED
JBL

COMMENTS:
Filtered sample for RCRA Metals - filters kept clogging hence the long sampling time above

SAMPLED BY: JBL	DATE: 7/26/06

TABLE NOTES	
	Although the American Community Survey (ACS) produces population, demographic and housing unit estimates, the decennial census is the official source of population totals for April 1st of each decennial year. In between censuses, the Census Bureau's Population Estimates Program produces and disseminates the official estimates of the population for the nation, states, counties, cities, and towns and estimates of housing units for states and counties.
	Information about the American Community Survey (ACS) can be found on the ACS website. Supporting documentation including code lists, subject definitions, data accuracy, and statistical testing, and a full list of ACS tables and table shells (without estimates) can be found on the Technical Documentation section of the ACS website. Sample size and data quality measures (including coverage rates, allocation rates, and response rates) can be found on the American Community Survey website in the Methodology section.
	Source: U.S. Census Bureau, 2018-2022 American Community Survey 5-Year Estimates
	Data are based on a sample and are subject to sampling variability. The degree of uncertainty for an estimate arising from sampling variability is represented through the use of a margin of error. The value shown here is the 90 percent margin of error. The margin of error can be interpreted roughly as providing a 90 percent probability that the interval defined by the estimate minus the margin of error and the estimate plus the margin of error (the lower and upper confidence bounds) contains the true value. In addition to sampling variability, the ACS estimates are subject to nonsampling error (for a discussion of nonsampling variability, see ACS Technical Documentation). The effect of nonsampling error is not represented in these tables.
	When information is missing or inconsistent, the Census Bureau logically assigns an acceptable value using the response to a related question or questions. If a logical assignment is not possible, data are filled using a statistical process called allocation, which uses a similar individual or household to provide a donor value. The "Allocated" section is the number of respondents who received an allocated value for a particular subject.

	Between 2018 and 2019 the American Community Survey retirement income question changed. These changes resulted in an increase in both the number of households reporting retirement income and higher aggregate retirement income at the national level. For more information see Changes to the Retirement Income Question .
	The 2018-2022 American Community Survey (ACS) data generally reflect the March 2020 Office of Management and Budget (OMB) delineations of metropolitan and micropolitan statistical areas. In certain instances, the names, codes, and boundaries of the principal cities shown in ACS tables may differ from the OMB delineation lists due to differences in the effective dates of the geographic entities.
	Estimates of urban and rural populations, housing units, and characteristics reflect boundaries of urban areas defined based on 2020 Census data. As a result, data for urban and rural areas from the ACS do not necessarily reflect the results of ongoing urbanization.
	Explanation of Symbols:- The estimate could not be computed because there were an insufficient number of sample observations. For a ratio of medians estimate, one or both of the median estimates falls in the lowest interval or highest interval of an open-ended distribution. For a 5-year median estimate, the margin of error associated with a median was larger than the median itself.N The estimate or margin of error cannot be displayed because there were an insufficient number of sample cases in the selected geographic area. (X) The estimate or margin of error is not applicable or not available.median- The median falls in the lowest interval of an open-ended distribution (for example "2,500-")median+ The median falls in the highest interval of an open-ended distribution (for example "250,000+").** The margin of error could not be computed because there were an insufficient number of sample observations.*** The margin of error could not be computed because the median falls in the lowest interval or highest interval of an open-ended distribution.***** A margin of error is not appropriate because the corresponding estimate is controlled to an independent population or housing estimate. Effectively, the corresponding estimate has no sampling error and the margin of error may be treated as zero.

	Source: U.S. Census Bureau, 2018-2022 American Community Survey 5-Year Estimates
	Data are based on a sample and are subject to sampling variability. The degree of uncertainty for an estimate arising from sampling variability is represented through the use of a margin of error. The value shown here is the 90 percent margin of error. The margin of error can be interpreted roughly as providing a 90 percent probability that the interval defined by the estimate minus the margin of error and the estimate plus the margin of error (the lower and upper confidence bounds) contains the true value. In addition to sampling variability, the ACS estimates are subject to nonsampling error (for a discussion of nonsampling variability, see ACS Technical Documentation). The effect of nonsampling error is not represented in these tables.
	Employment and unemployment estimates may vary from the official labor force data released by the Bureau of Labor Statistics because of differences in survey design and data collection. For guidance on differences in employment and unemployment estimates from different sources go to Labor Force Guidance.
	Workers include members of the Armed Forces and civilians who were at work last week.

	Industry titles and their 4-digit codes are based on the 2017 North American Industry Classification System. The Industry categories adhere to the guidelines issued in Clarification Memorandum No. 2, "NAICS Alternate Aggregation Structure for Use By U.S. Statistical Agencies," issued by the Office of Management and Budget.
	Occupation titles and their 4-digit codes are based on the 2018 Standard Occupational Classification.
	Logical coverage edits applying a rules-based assignment of Medicaid, Medicare and military health coverage were added as of 2009 -- please see https://www.census.gov/library/working-papers/2010/demo/coverage_edits_final.html for more details. Select geographies of 2008 data comparable to the 2009 and later tables are available at https://www.census.gov/data/tables/time-series/acs/1-year-re-run-health-insurance.html. The health insurance coverage category names were modified in 2010. See https://www.census.gov/topics/health/health-insurance/about/glossary.html#par_textimage_18 for a list of the insurance type definitions.
	Beginning in 2017, selected variable categories were updated, including age-categories, income-to-poverty ratio (IPR) categories, and the age universe for certain employment and education variables. See user note entitled "Health Insurance Table Updates" for further details.
	Several means of transportation to work categories were updated in 2019. For more information, see: Change to Means of Transportation.
	Between 2018 and 2019 the American Community Survey retirement income question changed. These changes resulted in an increase in both the number of households reporting retirement income and higher aggregate retirement income at the national level. For more information see Changes to the Retirement Income Question .
	The categories for relationship to householder were revised in 2019. For more information see Revisions to the Relationship to Household item.
	In 2019, methodological changes were made to the class of worker question. These changes involved modifications to the question wording, the category wording, and the visual format of the categories on the questionnaire. The format for the class of worker categories are now listed under the headings "Private Sector Employee," "Government Employee," and "Self-Employed or Other." Additionally, the category of Active Duty was added as one of the response categories under the "Government Employee" section for the mail questionnaire. For more detailed information about the 2019 changes, see the 2016 American Community Survey Content Test Report for Class of Worker located at http://www.census.gov/library/working-papers/2017/acs/2017_Martinez_01.html.
	Beginning in data year 2019, respondents to the Weeks Worked question provided an integer value for the number of weeks worked. For data years 2008 through 2018, respondents selected a category corresponding to the number of weeks worked.

	The 2018-2022 American Community Survey (ACS) data generally reflect the March 2020 Office of Management and Budget (OMB) delineations of metropolitan and micropolitan statistical areas. In certain instances, the names, codes, and boundaries of the principal cities shown in ACS tables may differ from the OMB delineation lists due to differences in the effective dates of the geographic entities.
	Estimates of urban and rural populations, housing units, and characteristics reflect boundaries of urban areas defined based on 2020 Census data. As a result, data for urban and rural areas from the ACS do not necessarily reflect the results of ongoing urbanization.
	Explanation of Symbols:- The estimate could not be computed because there were an insufficient number of sample observations. For a ratio of medians estimate, one or both of the median estimates falls in the lowest interval or highest interval of an open-ended distribution. For a 5-year median estimate, the margin of error associated with a median was larger than the median itself.N The estimate or margin of error cannot be displayed because there were an insufficient number of sample cases in the selected geographic area. Evaluation of Dredged Material Proposed For Discharge in Waters of the U.S. - Testing Manual

Inland Testing Manual

EVALUATION OF DREDGED MATERIAL PROPOSED FOR DISCHARGE IN WATERS OF THE U.S. - TESTING MANUAL

(INLAND TESTING MANUAL)

Prepared by

ENVIRONMENTAL PROTECTION AGENCY
Office of Water
Office of Science and Technology
Washington, D.C.

and

DEPARTMENT OF THE ARMY
United States Army Corps of Engineers
Operations, Construction, and Readiness Division
Washington, D.C.

February 1998

The testing protocols set out in the Inland Testing Manual are intended solely as guidance for use in conducting testing of dredged material to assess the potential for contaminant-related impacts associated with dredged material disposal into open water. The Manual does not alter the statutory and regulatory framework for permitting decisions under section 404 of the CWA. Under that framework, testing is conducted in order to assist the permitting authority in making factual determinations regarding the effect of the discharge on the aquatic ecosystem, and in determining whether the discharge will comply with the 404(b)(1) Guidelines. See 40 C.F.R. 230.10 and 230.11. The current regulations provide for testing under certain circumstances, and this Manual provides suggested protocols to follow once it has been decided that testing is appropriate. The Guidelines provide flexibility to the permitting authority to decide, based upon the facts of a particular case, whether testing is warranted.

The Manual is intended solely as guidance. The Manual is not intended, nor can it be relied upon, to create any rights or obligations enforceable by any party. The Manual provides the best available technical guidance regarding how dredged material should be tested. While it is generally anticipated that the Agencies will follow the procedures in this Manual, Agency decision-makers retain the discretion to adopt approaches on a case-by-case basis that differ from the guidance in the Manual where determined to be appropriate. The document does not, and is not intended to, impose any legally-binding requirements on Federal agencies, States, or the regulated community.

PREFACE

The "Evaluation of Dredged Material Proposed for Discharge in Waters of the U.S. - Testing Manual", commonly referred to as the Inland Testing Manual represents a major effort by the U.S. Army Corps of Engineers (USACE) and the Environmental Protection Agency (EPA) to establish procedures applicable to the evaluation of potential contaminant-related environmental impacts associated with the discharge of dredged material in inland waters, near coastal waters, and surrounding environs (that is, all waters other than the ocean and the territorial seas, regulated pursuant to Section 404, CWA). This manual is consistent, to the maximum extent practicable, with the procedures established for ocean waters (i.e., the "Green Book" entitled "Evaluation of Dredged Material Proposed for Ocean Disposal - Testing Manual" - EPA/USACE, 1991). The USACE and EPA have statutory and regulatory responsibilities with regard to the management of dredged material discharge activities in inland and near coastal waters. The USACE is responsible for regulating non-Federal dredging and dredged material discharge activities through a permit program, and for conducting Federal dredging and dredged material discharge activities in conjunction with its Civil Works Program. EPA is responsible for establishing, in conjunction with the USACE, guidelines pertaining to the evaluation of these activities, and performing oversight actions. Specifically, Section 404 of the Federal Water Pollution Control Act of 1972 (FWPCA), Public Law 92-500, as amended by the Clean Water Act of 1977 (CWA), Public Law 95-217, requires, among other things, that the discharge of dredged or fill material into waters of the U.S. be permitted by the USACE. The USACE also conducts Civil Works dredging and dredged material discharge activities in accordance with Section 404. Section 404 further requires that discharge sites be specified though the application of the Section 404(b)(1) Guidelines (Guidelines) developed by EPA in conjunction with the USACE. Section 404 requires that the "guidelines shall be based upon criteria comparable to the criteria applicable to the territorial seas, contiguous zone, and the ocean". Thus, a clear connection for comparable testing for ocean, inland and near coastal waters was established as early as 1972.

The Guidelines, which impart other requirements in addition to those associated with contaminant-related impacts, are published at 40 CFR 230. This manual provides testing procedures applicable to determining the potential for contaminant-related environmental impacts associated with the discharge of dredged material. Dredged material evaluated under the procedures described in this manual must also satisfy all other applicable requirements of 40 CFR 230-232, 33 CFR 320-330, and 33 CFR 335-338 in order to comply with the Guidelines and to be authorized for discharge.

This manual, which is designed to allow for regional flexibility in implementation and application including development of regional manuals and documentation, will be periodically revised and updated as warranted by advances in regulatory practice and technical understanding. This manual replaces the May 1976 proposed testing protocol, "Ecological Evaluation of Proposed Discharge of Dredged or Fill Material Into Navigable Waters", which will no longer be applicable. The 1976 protocol was developed in response to a requirement in the Federal Register notice of the Guidelines, Vol. 40, No. 173, Friday, 5 September 1975. That notice states the "EPA in conjunction with the Corps of Engineers will publish a procedures manual that will cover summary and description of tests, definitions, sample collection and preservation, procedures, calculations and references." In December 1980, the Guidelines were revised and finalized in the Federal Register Vol. 45, No. 249. The present joint effort by EPA and USACE contains up-to-date testing procedures to implement the Guidelines at Sections 230.60 and 230.61, and is

intended to bring compatibility and a comparable level of environmental protection for dredged material testing in ocean, inland and near coastal waters.

This manual is one of a series of guidance documents jointly developed by EPA and the USACE pertaining to dredged material disposal. This series includes a document entitled "Evaluating Environmental Effects of Dredged Material Management Alternatives - A Technical Framework" (Framework Document - USACE/EPA, 1992). The Framework Document articulates those factors to be considered in identifying the environmental effects of dredged material management alternatives on a continuum of discharge sites from uplands to the oceans (management alternatives include open water, confined and beneficial use situations) that meet the substantive and procedural requirements of the National Environmental Policy Act (NEPA), the CWA and the Marine Protection, Research, and Sanctuaries Act (MPRSA). The Green Book (EPA/USACE, 1991) is included in the series. Application of the testing guidance in this manual in addition to guidance provided in the Framework Document and the Green Book will allow for consistency in decision making with respect to technical considerations, across statutory boundaries and the continuum of dredged material discharge options.

The contributions made by many individuals from both agencies are gratefully acknowledged. The first and second drafts of the manual were completed by the Environmental Laboratory (EL) of the USACE Waterways Experiment Station (WES): Thomas Wright, primary author; Michael Palermo, author of Appendix B; Paul Schroeder, Michael Palermo, Robert Randall and Billy Johnson, authors of Appendix C. Succeeding drafts were completed by an EPA/USACE Workgroup established by EPA's Office of Science and Technology (OST) within the Office of Water (OW). Mike Kravitz of OST was the Work Assignment Manager. Appendix D was written by Dennis Brandon and Joan Clarke (WES) and Michael Paine (EVS Consultants). Appendix F was written by Gary Ankley (EPA). Appendix G was written by Sandra Salazar and Peter Chapman (EVS Consultants). Henry Lee and Bruce Boese (EPA) contributed valuable information pertaining to sediment bioaccumulation testing. Carie Schaffer and Robert Johnson (Tetra Tech, Inc.) provided computer support for internet and electronic versions of the document, respectively.

The Workgroup was comprised of individuals from headquarters, field offices and research laboratories of both agencies with scientific and/or programmatic experience related to dredged material discharge activities.

Co-Chairs:	Betsy Southerland	EPA/OW/OST
	Kirk Stark	USACE/Headquarters
Members:	Gary Ankley	EPA/Duluth Research Lab
	Tom Dillon	USACE/WES
	Wade Eakle	USACE/San Francisco Dist.
	Robert Engler	USACE/WES
	John Goodin	EPA/OW/OWOW
	Mike Kravitz	EPA/OW/OST
	John Malek	EPA/Region 10
	David Mathis	USACE/Headquarters
	Jan Miller	USACE/North Central Div.

	Dave Tomey	EPA/Region 1
	Joe Wilson	USACE/Headquarters
	Thomas Wright	USACE/WES
	Howard Zar	EPA/Region 5
Contractor:	Peter Chapman	EVS Environment Consultants

Review of this manual was conducted by EPA through OW [OST and the Office of Wetlands, Oceans and Watersheds (OWOW)] and by USACE through the Office of the Chief of Engineers (Regulatory Branch, Dredging and Navigation Branch, Office of Environmental Policy) and EL of WES. In addition, the results of the EPA's Science Advisory Board (SAB, 1992) review of the 1991 Green Book were considered in detail, where applicable, during development of this manual. The results of EPA's SAB (1994) review of the draft Inland Testing Manual were considered during its finalization. Regional issues which have National relevance were provided by EPA Region and USACE Division and District staff, and were incorporated into the appropriate sections of this document. This manual provides comprehensive testing guidance from a national perspective. Within the framework of this document, EPA Regions and USACE Districts and Divisions will develop region-specific guidance and/or procedures, as necessary (e.g., region-specific test species), to provide sufficient information to make informed dredged material discharge decisions.

This manual should be cited as follows:

EPA/USACE. 1998. Evaluation of dredged material proposed for discharge in waters of the U.S. - Testing manual. EPA-823-B-98-004, Washington, D.C.

DEFINITIONS

The following definitions of words and terms are specific to the use of this manual and, where applicable, are quoted verbatim from the Guidelines (cf. Definitions at 40 CFR 230.3 and/or other parts; such definitions are starred*). Thorough familiarization with the following definitions is required prior to use of this manual.

Accuracy: The ability to obtain a true value; determined by the degree of agreement between an observed value and an accepted reference value.

Acid volatile sulfide (AVS): The sulfides removed from sediment by cold acid extraction, consisting mainly of H_2S and FeS. AVS is a possible predictive tool for divalent metal sediment toxicity.

Acute: Having a sudden onset, lasting a short time.

Acute toxicity: Short-term toxicity to organism(s) that have been affected by the properties of a substance, such as contaminated sediment. The acute toxicity of a sediment is generally determined by quantifying the mortality of appropriately sensitive organisms that are put into contact with the sediment, under either field or laboratory conditions, for a specified period.

***Adjacent:** Bordering, contiguous or neighboring. Wetlands separated from other waters of the United States by man-made dikes or barriers, natural river berms, beach dunes and the like are "adjacent wetlands".

Application factor (AF): A numerical, unitless value, calculated as the threshold chronically toxic concentration of a test substance divided by its acutely toxic concentration. The AF is usually reported as a range and is multiplied by the median lethal concentration as determined in a short-term (acute) toxicity test to estimate an expected no-effect concentration under chronic exposure.

Benchmark organism: Test organism designated by USACE and EPA as appropriately sensitive and useful for determining biological data applicable to the real world. Test protocols with such organisms are published, reproducible and standardized.

Bioaccumulation: The accumulation of contaminants in the tissue of organisms through any route, including respiration, ingestion, or direct contact with contaminated water, sediment, pore water or dredged material. [The regulations require that bioaccumulation be considered as part of the environmental evaluation of dredged material proposed for disposal. This consideration involves predicting whether there will be a cause-and-effect relationship between an organism's presence in the area influenced by the dredged material and an environmentally important elevation of its tissue content or body burden of contaminants above that in similar animals not influenced by the disposal of the dredged material].

Bioaccumulation factor: The degree to which an organism accumulates a chemical compared to the source. It is a dimensionless number or factor derived by dividing the concentration in the organism by that in the source.

Bioassay: A bioassay is a test using a biological system. It involves exposing an organism to a test material and determining a response. There are two major types of bioassays differentiated by response: **toxicity tests** which measure an effect (e.g., acute toxicity, sublethal/chronic toxicity) and **bioaccumulation tests** which measure a phenomenon (e.g., the uptake of contaminants into tissues).

Bioavailable: Can affect organisms.

Bioconcentration: Uptake of a substance from water.

Biomagnification: Bioaccumulation up the food chain, e.g., the route of accumulation is solely through food. Organisms at higher trophic levels will have higher body burdens than those at lower trophic levels.

Biota sediment accumulation factor: Relative concentration of a substance in the tissues of an organism compared to the concentration of the same substance in the sediment.

Bulk sediment chemistry: Results of chemical analyses of whole sediments (in terms of wet or dry weight), without normalization (e.g., to organic carbon, grain-size, acid volatile sulfide).

Can: Is used to mean "is able to".

Chronic: Involving a stimulus that is lingering or which continues for a long time.

Chronic toxicity: See **sublethal/chronic toxicity**.

Comparability: The confidence with which one data set can be compared to others and the expression of results consistent with other organizations reporting similar data. Comparability of procedures also implies using methodologies that produce results comparable in terms of precision and bias.

Completeness: A measure of the amount of valid data *obtained* versus the amount of data originally *intended* to be collected.

Confined disposal: A disposal method that isolates the dredged material from the environment. Confined disposal is placement of dredged material within diked confined disposal facilities via pipeline or other means.

Confined disposal facility (CDF): A diked area, either in-water or upland, used to contain dredged material. The terms confined disposal facility (CDF), dredged material containment area, diked disposal facility, and confined disposal area are used interchangeably.

Constituents: Chemical substances, solids, liquids, organic matter, and organisms associated with or contained in or on dredged material.

***Contaminant:** A chemical or biological substance in a form that can be incorporated into, onto or be ingested by and that harms aquatic organisms, consumers of aquatic organisms, or users of the aquatic environment, and includes but is not limited to the substances on the 307(a)(1) list of toxic pollutants promulgated on January 31, 1978 (43 FR 4109). [Note: A contaminant that causes actual harm is technically referred to as a pollutant, but the regulatory definition of a "pollutant" in the Guidelines is different, reflecting the intent of the CWA.]

Contaminant of concern: A contaminant present in a given sediment thought to have the potential for unacceptable adverse environmental impact due to a proposed discharge.

Control sediment: A sediment essentially free of contaminants and which is used routinely to assess the acceptability of a test. Control sediment may be the sediment from which the test organisms are collected or a laboratory sediment, provided the organisms meet control standards. Test procedures are conducted with the control sediment in the same way as the reference sediment and dredged material. The purpose of the control sediment is to confirm the biological acceptability of the test conditions and to help verify the health of the organisms during the test. Excessive mortality in

the control sediment indicates a problem with the test conditions or organisms, and can invalidate the results of the corresponding dredged material test.

Data quality indicators: Quantitative statistics and qualitative descriptors which are used to interpret the degree of acceptability or utility of data to the user; include bias (systematic error), precision, accuracy, comparability, completeness, representativeness, detectability and statistical confidence.

Data quality objectives (DQOs): Qualitative and quantitative statements of the overall uncertainty that a decision maker is willing to accept in results or decisions derived from environmental data. DQOs provide the framework for planning environmental data operations consistent with the data user's needs.

Discharge of dredged material: Any addition of dredged material into waters of the United States. [Dredged material discharges include: open water discharges; discharges resulting from unconfined disposal operations (such as beach nourishment or other beneficial uses); discharges from confined disposal facilities which enter waters of the United States (such as effluent, surface runoff, or leachate); and, overflow from dredge hoppers, scows, or other transport vessels]. Material resuspended during normal dredging operations is considered "de minimus" and is not regulated under Section 404 as a dredged material discharge. See 33 CFR 323.2 for a detailed definition. The potential impact of resuspension due to dredging can be addressed under NEPA.

***Disposal site:** That portion of the "waters of the United States" where specific disposal activities are permitted and consist of a bottom surface area and any overlying volume of water. In the case of wetlands on which surface water is not present, the disposal site consists of the wetland surface area. [Note: upland locations, although not mentioned in this definition in the Regulations, can also be disposal sites].

District: A USACE administrative area.

***Dredged material:** Material that is excavated or dredged from waters of the United States. [A general discussion of the nature of dredged material is provided by Engler et al. (1991a)].

EC_{50}: The median effective concentration. The concentration of a substance that causes a specified effect (generally sublethal rather than acutely lethal) in 50% of the organisms tested in a laboratory toxicity test of specified duration.

Elutriate: Material prepared from the sediment dilution water and used for chemical analyses and toxicity testing. Different types of elutriates are prepared for two different procedures as noted in this manual.

Evaluation: The process of judging data in order to reach a decision.

***Factual determination**: A determination in writing of the potential short-term or long-term effects of a proposed discharge of dredged or fill material on the physical, chemical and biological components of the aquatic environment in light of Subparts C-F of the Guidelines.

Federal Standard: The dredged material disposal alternative(s) identified by the U.S. Army Corps of Engineers that represent the least costly, environmentally acceptable alternative(s) consistent with sound engineering practices and which meet the environmental standards established by the 404(b)(1) evaluation process. [See Engler et al. (1988) and 33 CFR 335-338].

***Fill material:** Any material used for the primary purpose of replacing an aquatic area with dry land or changing the bottom elevation of a water body for any purpose. The term does not include any pollutant discharged into the water primarily to dispose of waste, as that activity is regulated under Section 402 of the Clean Water Act. [Note: dredged material can be used as fill material].

Grain-size effects: Mortality or other effects in laboratory toxicity tests due to sediment granulometry, not chemical toxicity. [It is clearly best to use test organisms which are not likely to react to grain-size but, if this is not reasonably possible, then testing must account for any grain-size effects.]

Guidelines: Substantive environmental criteria by which proposed discharges of dredged material are evaluated. CWA Section 404(b)(1) final rule (40 CFR 230) promulgated December 24, 1980.

LC_{50}: The median lethal concentration. The concentration of a substance that kills 50% of the organisms tested in a laboratory toxicity test of specified duration.

Leachate: Water or any other liquid that may contain dissolved (leached) soluble materials, such as organic salts and mineral salts, derived from a solid material.

Lethal: Causing death.

Loading density: The ratio of organism biomass or numbers to the volume of test solution in an exposure chamber.

Management actions: Those actions considered necessary to rapidly render harmless the material proposed for discharge (e.g., non-toxic, non-bioaccumulative) and which may include containment in or out of the waters of the U.S. (see 40 CFR Subpart H). Management actions are employed to reduce adverse impacts of proposed discharges of dredged material.

Management unit: A manageable, dredgeable unit of sediment which can be differentiated by sampling and which can be separately dredged and disposed within a larger dredging area. Management units are not differentiated solely on physical or other measures or tests but are also based on site- and project-specific considerations.

May: Is used to mean "is allowed to".

Method detection limit (MDL): The minimum concentration of a substance which can be identified, measured, and reported with 99% confidence that the analyte concentration is greater than zero.

Might: Is used to mean "could possibly."

***Mixing zone:** A limited volume of water serving as a zone of initial dilution in the immediate vicinity of a discharge point where receiving water quality may not meet quality standards or other requirements otherwise applicable to the receiving water. [The mixing zone may be defined by the volume and/or the surface area of the disposal site or specific mixing zone definitions in State water quality standards].

Must: In this manual refers to requirements that have to be addressed in the context of compliance with the Guidelines.

Open water disposal: Placement of dredged material in rivers, lakes or estuaries via pipeline or surface release from hopper dredges or barges.

Pathway: In the case of bioavailable contaminants, the route of exposure (e.g., water, food).

***Pollution:** The man-made or man-induced alteration of the chemical, physical, biological or radiological integrity of an aquatic ecosystem. [See definition of **contaminant**].

***Practicable:** Available and capable of being done after taking into consideration cost, existing technology, and logistics in light of overall project purposes.

Practical quantitation limit (PQL): The lowest concentration that can be reliably quantified with specified limits of precision and accuracy during routine laboratory operating conditions.

Precision: The ability to replicate a value; the degree to which observations or measurements of the same property, usually obtained under similar conditions, conform to themselves. Usually expressed as standard deviation, variance or range.

QA: Quality assurance, the total integrated program for assuring the reliability of data. A system for integrating the quality planning, quality control, quality assessment, and quality improvement efforts to meet user requirements and defined standards of quality with a stated level of confidence.

QC: Quality control, the overall system of technical activities for obtaining prescribed standards of performance in the monitoring and measurement process to meet user requirements.

Reason to believe: Subpart G of the 404(b) (1) guidelines requires the use of available information to make a preliminary determination concerning the need for testing of the material proposed for dredging. This principle is commonly known as "reason to believe", and is contained in Tier I of the tiered testing framework. The decision to not perform additional testing based on prior information must be documented, in order to provide a "reasonable assurance that the proposed discharge material is not a carrier of contaminants" (230.60(b)).

Reference sediment: Point of comparison for evaluating test sediment. Testing requirements in the Section 404(b)(1) Guidelines regarding the point of comparison for evaluating proposed discharges of dredged material are being updated to provide for comparison to a "reference sediment" as opposed to sediment from the disposal site. Because subsequent discharges at a disposal site could adversely impact the point of comparison, adoption of a reference sediment that is unimpacted by previous discharges of dredged material will result in a more scientifically sound evaluation of potential individual and cumulative contaminant-related impacts. This change to the Guidelines was proposed in the Federal Register in January 1995, public comments have been received, and a final rule Notice is being prepared. It is expected that the final rule will be published prior to July 1, 1998, and as a result the reference sediment approach will be implemented in the ITM.

Reference site: The location from which **reference sediment** is obtained.

Region: An EPA administrative area.

region: A geographical area.

Regulations: Procedures and concepts published in the Code of Federal Regulations for evaluating the discharge of dredged material into waters of the United States.

Representativeness: The degree to which sample data depict an existing environmental condition; a measure of the total variability associated with sampling and measuring that includes the two major error components: systematic error (bias) and random error. Sampling representativeness is accomplished through proper selection of sampling locations and sampling techniques, collection of sufficient number of samples, and use of appropriate subsampling and handling techniques.

Sediment: Material, such as sand, silt, or clay, suspended in or settled on the bottom of a water body.

Should: Is used to state that the specified condition is recommended and ought to be met unless there are clear and definite reasons not to do so.

Standard operating procedure (SOP): A written document which details an operation, analysis, or action whose mechanisms are thoroughly prescribed and which is commonly accepted as the method for performing certain routine or repetitive tasks.

Standardized: In the case of methodology, a published procedure which has been peer reviewed (e.g., journal, technical report), and generally accepted by the relevant technical community of experts.

Sublethal: Not directly causing death; producing less obvious effects on behavior, biochemical and/or physiological function, histology of organisms.

Sublethal/chronic toxicity: Biological tests which use such factors as abnormal development, growth and reproduction, rather than solely lethality, as end-points. These tests involve all or at least an important, sensitive portion of an organism's life-history. A sublethal endpoint may result either from short-term or long-term (chronic) exposures.

Target detection limit: A performance goal set by consensus between the lowest, technically feasible, detection limit for routine analytical methods and available regulatory criteria or guidelines for evaluating dredged material. The target detection limit is, therefore, equal to or greater than the lowest amount of a chemical that can be reliably detected based on the variability of the blank response of routine analytical methods. However, the reliability of a chemical measurement generally increases as the concentration increases. Analytical costs may also be lower at higher detection limits. For these reasons, a target detection limit is typically set at not less than 10 times lower than available dredged material guidelines.

Tests/testing: Specific procedures which generate biological, chemical, and/or physical data to be used in evaluations. The data are usually quantitative but may be qualitative (e.g., taste, odor, organism behavior). Testing for discharges of dredged material in waters of the United States is specified at 40 CFR 230.60 and 230.61 and is implemented through the procedures in this manual.

Tiered approach: A structured, hierarchical procedure for determining data needs relative to decision-making, which involves a series of tiers or levels of intensity of investigation. Typically, tiered testing involves decreased uncertainty and increased available information with increasing tiers. This approach is intended to ensure the maintenance and protection of environmental quality, as well as the optimal use of resources. Specifically, least effort is required in situations where clear determinations can be made of whether (or not) unacceptable adverse impacts are likely to occur based on available information. Most effort is required where clear determinations cannot be made with available information.

Toxicity: see **Acute toxicity**; **Sublethal/chronic toxicity**, **Toxicity test**.

Toxicity test: A **bioassay** which measures an effect (e.g., acute toxicity, sublethal/chronic toxicity). Not a **bioaccumulation test** (see definition of **bioassay**).

Water quality certification: A state certification, pursuant to Section 401 of the Clean Water Act, that the proposed discharge of dredged material will comply with the applicable provisions of Sections 301, 303, 306 and 307 of the Clean Water Act and relevant State laws. Typically this certification is provided by the affected State. In instances where the State lacks jurisdiction (e.g., Tribal Lands), such certification is provided by EPA or the Tribe (with an approved certification program).

Water quality standard: A law or regulation that consists of the beneficial designated use or uses of a water body, the numeric and narrative water quality criteria that are necessary to protect the use or uses of that particular water body, and an anti-degradation statement.

Waters of the U.S.: In general, all waters landward of the baseline of the territorial sea and the territorial sea. Specifically, all waters defined in Section 230.3 (s) of the Guidelines. [See Appendix A].

Whole sediment: The sediment and interstitial waters of the proposed dredged material or reference sediment that have had minimal manipulation. For purposes of this manual, press-sieving to remove organisms from test sediments, homogenization of test sediments, compositing of sediment samples, and additions of small amounts of water to facilitate homogenizing or compositing sediments may be necessary to conducting bioassay tests. These procedures are considered unlikely to substantially alter chemical or toxicological properties of the respective whole sediments except in the case of AVS (acid volatile sulfide) measurements (EPA, 1991a) which are not presently required. Alternatively, wet sieving, elutriation, or freezing and thawing of sediments may alter chemical and/or toxicological properties, and sediment so processed should not be considered as whole sediment for bioassay purposes.

LIST OF ACRONYMS

AAS - Atomic Absorption Spectrometry
AF - Application Factor
AVS - Acid Volatile Sulfide
BAF - Bioaccumulation Factor
BCF - Bioconcentration Factor
BSAF - Biota Sediment Accumulation Factor
CDF - Confined Disposal Facility
CFR - Code of Federal Regulations
CLP - Contract Laboratory Program
CWA - Clean Water Act
ECD - Electron Capture Detection
EO - Executive Orders
EPA - Environmental Protection Agency
FDA - Food and Drug Administration
FR - Federal Register
GC - Gas Chromatography
GFAAS - Graphite Furnace Atomic Absorption Spectrometry
IAEA - International Atomic Energy Agency
ICP - Inductively Coupled Plasma
ITM - Inland Testing Manual
LBP - Lipid Bioaccumulation Potential
MPRSA - Marine Protection, Research and Sanctuaries Act
MS - Mass Spectrometry
NBS - National Bureau of Standards
NEPA - National Environmental Policy Act
NIST - National Institute for Standards and Technology
NOAA - National Oceanic Atmospheric Administration
NPDES - National Pollutant Discharge Elimination System
NRC - National Research Council of Canada
PAH - Polynuclear Aromatic Hydrocarbons
PCB - Polychlorinated Biphenyl
QA - Quality Assurance

QC - Quality Control
QSAR - Quantitative Structure Activity Relationship
RHA - Rivers and Harbors Act of 1899
SAB - Science Advisory Board
SIM - Selected Ion Monitoring
SOP - Standard Operating Procedure
SQC - Sediment Quality Criteria
SQS - Sediment Quality Standards
SRM - Standard Reference Material
TBP - Theoretical Bioaccumulation Potential
TDL - Target Detection Limit
TEF - Toxicity Equivalency Factor
TOC - Total Organic Carbon
TIE - Toxicity Identification Evaluation
USACE - U.S. Army Corps of Engineers
USCS - Unified Soil Classification System
WQC - Water Quality Criteria
WQS - Water Quality Standards

1cc = $10^{-6}m^3$	1 gallon (US) = 3785cc
	1 ft^3 = 0.0283m^3= 28.3168 L
FLOW:	
1m/s = 196.850 ft/min = 3.281 ft/s	1 ft^3/s = 1699.011 L/min = 28.317 L/s
1 m^3/s = 35.7 ft^3/s	1 ft^2/hr = 2.778 x 10^{-4} ft^2/s = 2.581 x $10^{-5}m^2$/s
	1 ft/s = 0.03048m/s
	1 yd^3/min = 0.45ft^3/s
	yd^3/s = 3.366 gal/s = 12.743 L/s
AREA:	
1 m^2 = 10.764ft^2	1 ft^2 = 0.0929m^2
1 hectare (ha) = 10000m^2 = 2.471 acres	1 acre = 4046.856m^2 = 0.405 ha

PART I - GENERAL CONSIDERATIONS

1.0 INTRODUCTION

1.1 Background

The "Evaluation of Dredged Material Proposed for Discharge in Waters of the U.S. - Testing Manual", commonly referred to as the Inland Testing Manual, updates and replaces "Ecological Evaluation of Proposed Discharge of Dredged or Fill Material into Navigable Waters" (USACE, 1976). This updated manual contains technical guidance for determining the potential for contaminant-related impacts associated with the discharge of dredged material in waters regulated under Section 404 of the CWA (inland waters, near coastal waters, and surrounding environs) through chemical, physical, and biological evaluations. The technical guidance in the manual is intended for use by Army Corps of Engineers (USACE) and Environmental Protection Agency (EPA) personnel, state regulatory personnel, as well as dredging permit applicants and others (e.g., scientists, managers, and other involved or concerned individuals). The results obtained will be utilized within the context of regulatory requirements (discussed in the following sections), to facilitate decision-making with regard to the management of dredged material.

Key changes to the 1976 testing protocol include a tiered testing approach, accommodation for sediment quality standards (SQS), 28-d bioaccumulation testing, comparison of benthic test results with those of the reference sediment, improved statistics, improved model applications, and new test organisms. Because this manual is national in scope, the guidance provided is generic and may need to be modified in certain instances. Application of this guidance in some site- and case-specific situations will require best professional judgment, appropriately documented. Permit applicants and others are strongly encouraged to consult with their appropriate Regional and District experts for additional guidance.

1.2 Statutory/Regulatory Overview

The following sections provide a discussion of the statutory and regulatory framework of the Federal programs within which decisions regarding the management of dredged material discharge activities are made.

1.2.1 Statutory Overview

The USACE and EPA share the Federal responsibility for regulating the discharge of dredged material. The Clean Water Act (CWA) governs discharges of dredged material into "waters of the United States",

including all waters landward of the baseline of the territorial sea. The Marine Protection, Research, and Sanctuaries Act (MPRSA) governs the transportation of dredged material seaward of the baseline (in ocean waters) for the purpose of disposal. In addition, all activities regulated by these statutes must comply with the applicable requirements of the National Environmental Policy Act (NEPA), as well as other Federal laws, regulations and Executive Orders which apply to activities involving the discharge of dredged material.

The CWA was enacted by Congress to "restore and maintain the chemical, physical, and biological integrity of the Nation's waters." The CWA created three permit programs, under Section 401 (as a certification), Section 402 and Section 404, to regulate the point-source discharge of pollutants into waters of the U.S. EPA administers Section 402 which established the National Pollutant Discharge Elimination System (NPDES) Program to regulate discharges of chemicals, heavy metals, and biological wastes, primarily in waste water from industrial processes, publicly owned sewage treatment works, and stormwater discharges. The Section 402 program may be delegated by EPA to the States to administer. EPA and USACE each administer specific aspects of Section 404 which established a permit program and technical guidelines to regulate discharges of dredged or fill material (dredged material and fill material disposal sites must be "specified"). States may assume (and most of them have) the program administered by EPA under Section 401 and must grant, deny, or waive certification for activities permitted or conducted by USACE based on the potential impacts to water quality which may result from a discharge of dredged or fill material to waters of the U.S.

The USACE also administers a regulatory program under Section 10 of the Rivers and Harbors Act of 1899 (RHA) which regulates dredging and other construction activities in navigable waters. The USACE also operates a Federal Civil Works navigation program in conjunction with the CWA and with requirements established within Congressional authorization and appropriation statutes, which involves extensive dredging and dredged material discharge activities. These USACE programs are operated in accordance with NEPA which requires, among other things, the analysis and documentation of potential primary and secondary impacts, including those associated with dredging and dredged material discharges.

1.2.2 Section 404 Regulatory Overview

The USACE has the primary responsibility for the Section 404 regulatory permit program [the USACE regulatory program also administers Section 10 RHA, as well as Section 103 of the MPRSA (for the transport of dredged material to the ocean for the purpose of disposal)] and is authorized, after notice and opportunity for public comment, to issue permits specifying sites for the discharge of dredged or fill material. EPA has the primary role in developing the environmental guidelines, in conjunction with

USACE [the Section 404(b)(1) Guidelines (Guidelines)], by which permit applications must be evaluated. EPA is also responsible for commenting on proposed USACE permits, prohibiting discharges with unacceptable adverse aquatic environmental impacts, approving and overseeing State assumption of the program, establishing jurisdiction, and interpreting exemptions. Both USACE and EPA share enforcement authority.

The USACE regulates the discharge of dredged material, resulting from navigation dredging, into waters of the United States. The USACE also regulates the discharge of dredged material and incidental discharges of dredged material resulting from mechanized landclearing, ditching, channelization, and other excavation activities. The Inland Testing Manual has been developed to facilitate testing in conjunction with proposed dredged material discharges resulting from navigation dredging. The testing protocols are not designed or intended to be applied to discharge of dredged material and incidental discharges of dredged material resulting from mechanized landclearing, ditching, channelization, and other excavation activities, except where excavation and subsequent discharge activities are of essentially the same character as those associated with navigation dredging and disposal (e.g., open water discharges of dredged material excavated from a soft-bottom flood control channel or reservoir).

The USACE's evaluation of a Section 404 permit application involves determining whether the proposed project complies with the Guidelines (40 CFR 230) and USACE permit regulations (33 CFR 320-330) which require a public interest review of the project. [Public interest factors (listed in 33 CFR 320.4) considered with respect to dredged material contaminant-related impacts include water quality, water supply and conservation, safety, and fish and wildlife impacts]. A permit is issued provided the proposed project complies with the Guidelines and is not contrary to the public interest. The USACE issues individual permits and general permits. Individual permits are issued on a project-by-project basis after the Guidelines compliance and public interest determinations are made for the specific project at issue. General permits, on the other hand, are issued for classes of activities after the USACE conducts the Guidelines compliance and public interest reviews and determines that issuance of the general permit will not result in more than minimal adverse impacts to the aquatic environment from either a site-specific or cumulative standpoint. General permits require little or no reporting, analysis, or paperwork.

There are three types of general permits issued by the USACE, nationwide permits, regional general permits and programmatic general permits. Nationwide permits are issued by the Chief of Engineers and apply nationwide. Regional permits are issued by District and Division Engineers and are applicable on district or State-wide basis. Programmatic permits are issued (by the Chief of Engineers, as well as District and Division Engineers) to other federal, State or local agencies with the intention of providing the appropriate level of environmental protection and avoiding unnecessary duplication of effort with the agency regulatory activities at issue.

There are currently four nationwide permits that pertain to dredging and the discharge of dredged material. One authorizes the discharge and return water from confined disposal areas (provided the associated dredging is authorized pursuant to Section 10 of the River and Harbor Act of 1899); two other nationwide permits authorize the dredging and discharge, respectively, of up to 25 cubic yards of material; and a fourth authorizes maintenance dredging of existing marina basins (provided that the dredged material is deposited on uplands; return water from a confined disposal area requires separate authorization pursuant to Section 404 of the Clean Water Act). The USACE depends on its districts' knowledge of potentially contaminated areas and on the discretionary authority of District and Division Engineers to develop special conditions and/or require individual permits where contaminated sediments are present. General permits are not intended to apply to projects involving the dredging or the discharge of contaminated materials.

USACE Civil Works activities are conducted in accordance with the Guidelines and the USACE operation and maintenance regulations (33 CFR 335-338). The USACE specifies sites for the discharge of dredged material in conjunction with its regulatory and civil works responsibilities. (Permits are not actually issued in conjunction with USACE discharge activities).

1.2.2.1 The Section 404(b)(1) Guidelines

The Guidelines provide the substantive environmental criteria used in evaluating proposed discharges of dredged or fill material into waters of the United States. Fundamental to these Guidelines is the precept that dredged or fill material should not be discharged into the aquatic ecosystem, unless it can be demonstrated that such a discharge will not have an unacceptable adverse impact either individually or in combination with known and/or probable impacts of other activities affecting the ecosystems of concern.

For proposed discharges of dredged material to comply with the Guidelines, they must satisfy four requirements found in Section 230.10 as follows. Section 230.10(a) addresses those impacts associated with the loss of aquatic site functions and values of the proposed discharge site, by requiring that the discharge site represent the least environmentally damaging, practicable alternative. Section 230.10(b) requires compliance with established legal standards (e.g., issuance or waiver of a State water quality certification). Section 230.10(c) requires that discharge of dredged material not result in significant degradation of the aquatic ecosystem. Section 230.10(d) requires that all practicable means be utilized to minimize for adverse environmental impacts.

Testing as described in this manual is part of the larger evaluation of a proposed discharge activity to

determine its compliance with the Guidelines. Sections 230.60 and 230.61 of the Guidelines provide the basis for certain factual determinations with regard to dredged material discharge activities. Section 230.60 provides for a general evaluation of the material and establishes a framework to determine, based on existing information on the proposed dredging and discharge sites, whether the material at issue requires further testing. If the conditions at 230.60 cannot be met or are not applicable, the testing requirements of Section 230.61 must be applied. This manual details the testing procedures outlined in 230.60 and 230.61. Conclusions reached utilizing this manual will be used to make factual determinations of the potential effects of a proposed discharge of dredged or fill material on the physical, chemical and biological components of the aquatic environment. Such factual determinations are used to make findings of compliance or noncompliance with relevant parts of Sections 230.10(b) (including compliance with established water quality standards) and 230.10(c) (determinations of potential contaminant-related impacts to aquatic resources). All specifications of discharge sites must also comply with Section 230.10 (a) and Section 230.10(d). Site monitoring and/or management activities developed following the use of this manual may be said to contribute to satisfying the aforementioned requirements of Section 230.10(d).

Once compliance with the Guidelines is established, information developed utilizing the manual will also be factored into the USACE public interest determination which is required by its regulatory permit regulations for proposed non-Federal dredged material discharge activities, or its determinations required by the operation and maintenance regulations pertaining to Federal Civil Works activities. In making determinations with regard to its regulatory and civil works responsibilities, the USACE considers a continuum of discharge options, on a project-specific basis, including alternative sites, mitigation and specific site management and monitoring conditions. Determination of whether a material, which would not otherwise comply with the Guidelines or with other USACE regulatory and civil works requirements, could be brought into compliance through appropriate management actions or other discharge methods, is beyond the scope of this manual.

1.2.2.2 Particulars of Sections 230.60 and 230.61

Reason to Believe - Subpart G of the 404(b)(1) guidelines requires the use of available information to make a preliminary determination concerning the need for testing of the material proposed for dredging. This principle is commonly known as "reason to believe". The decision to not perform testing based on prior information must be documented in order to provide a "reasonable assurance that the proposed discharge material is not a carrier of contaminants" (by virtue of the fact that it is sufficiently removed from sources of pollution) [230.60(b)]. The reason to believe that no testing is required is based on the type of material to be dredged and/or its potential to be contaminated. For example, dredged material is most likely to be free of contaminants if the material is composed primarily of sand, gravel, or other

inert material and is found in areas of high current or wave energy [230.60(a)]. In addition, knowledge of the proposed dredging site proximity to other sources of contamination, as well as that gained from previous testing or through experience and knowledge of the area to be dredged, may be utilized to conclude that there is no reason to believe that contaminants are present [230.60(b)] and, therefore, no need for testing. This general evaluation comprises procedures found in Tier I of the manual's tiered-testing framework. Tier I is a comprehensive analysis of all existing and readily available information on the proposed dredging project, including all previously collected physical, chemical, and biological data for both the proposed dredging and discharge sites. A more complete discussion of technical factors to consider with respect to Sections 230.60(a) and (b) in Tier I is provided in Section 4.0.

Exclusions From Testing - Sections 230.60(c) and (d) provide for specific circumstances in which the discharge of dredged material which is suspected to be contaminated may be conducted without further testing. Section 230.60(c) provides that where the proposed discharge and dredging sites are adjacent and are comprised of similar materials and subject to the same source(s) of contaminants, disposal may be conducted without further testing because the discharge is not likely to result in degradation of the discharge site, as long as the potential spread of contaminants to less contaminated areas can be prevented. Section 230.60(d) provides that the discharge of contaminated dredged material may be conducted without further testing if constraints, acceptable to USACE and EPA, are available to reduce contamination to acceptable levels within the discharge site, and to prevent contaminants from being transported beyond the proposed discharge site boundaries.

Conclusions reached with regard to dredged material discharges without testing, in accordance with Section 230.60, must be described in the appropriate factual determination. Even though material may be excluded from testing under the manual the water quality certifying agency may require testing to demonstrate compliance with state laws. Even in cases where the discharge site is adjacent to the dredging site, potential differences in contaminant bioavailability may occur.

Reference Sediment - The manual requires comparison of testing results between the proposed dredged material and a reference sediment (see previous Definitions section). The USACE and EPA believe that the use of a reference sediment provides an accurate information base for predicting cumulative bioaccumulation and benthic impacts resulting from the discharge of dredged material.

1.2.3 Relationship to Section 401 CWA Water Quality Certification

Section 401 of the CWA requires that all Federal permits and licenses, including those for the discharge of dredged material into waters of the United States, authorized pursuant to Section 404 of the CWA,

must be certified as complying with applicable State water quality standards (WQS). The Guidelines at 40 CFR 230.10(b) state in part that "No discharge of dredged or fill material shall be permitted if it: (1) Causes or contributes, after consideration of disposal site dilution and dispersion, to violations of any applicable State water quality standard." This applies at the edge of a State designated mixing zone.

The process for adoption of State WQS is prescribed at 40 CFR 131. States must issue, condition, deny, or waive a Water Quality Certification for activities permitted or conducted by USACE, certifying that no adverse water quality impacts will occur based on determinations of compliance with applicable State WQS which have been adopted in accordance with the above regulation. State water quality standards consist of designated uses, narrative and numeric criteria designed to support those uses, and anti-degradation provisions. This testing manual is intended to provide guidance for the dredged material testing necessary to determine compliance with such State WQS.

States may, at their discretion, include in their State standards policies generally affecting their application and implementation, e.g. mixing zones (40 CFR 131.13). A mixing zone is a limited volume of water serving as a zone of initial dilution in the immediate vicinity of a discharge point where receiving water may not meet quality standards or other requirements otherwise applicable to the receiving water (40 CFR 230.3). Where mixing zone provisions are part of the State standards, the State should describe the procedures for defining mixing zones.

According to EPA (1991b), mixing zone concentrations should not exceed acute water quality standards and, considering likely pathways of exposure, there should be no significant human health risks. For dredged material discharges which only occur periodically, water quality standard compliance in the mixing zone is generally focused on aquatic life, not on human health, which is based on long-term exposures to contaminants. (Long-term exposures resulting from accumulations of dredged material at the disposal site can be evaluated by such means as bioaccumulation tests). Acute or chronic standards may be appropriate, depending on the duration of discharge and characteristics of the discharge site.

Many States have statutory or regulatory requirements for use of State-owned lands, including aquatic (marine and freshwater) bedlands. For discharges of dredged or fill materials into waters of the U.S. which are also waters of State or State-owned lands, specific requirements (including testing) for "use" of State lands may exist which need to be considered. The responsible State land-management agency may be different from the agency which normally issues the WQS or coastal zone certification. At a minimum, coordination with the responsible State agency should occur to avoid conflicts with or impacts to existing and/or future uses of State lands. In parts of the country, cooperative State-federal dredged material or sediment management ventures are in place or are being pursued to identify disposal sites, develop consistent regional management standards, and to monitor maintenance of those standards [e.g.,

the Puget Sound Dredged Material Disposal Analysis (State of Washington) and San Francisco Long-Term Management Strategy (LTMS - State of California)]. These programs are intended to streamline the regulatory process associated with dredging and dredged material disposal.

2.0 SCOPE AND APPLICABILITY

This manual is directed towards evaluation of proposed discharges of dredged material (associated with navigational dredging or dredging activities of essentially the same character as navigational dredging) in open water. It utilizes both chemical and biological analyses as necessary, to provide effects-based conclusions within a tiered framework with regard to the potential for contaminant-related water column, benthic toxicity and benthic bioaccumulation impacts. The tiered-testing procedure detailed in Section 3.1 is comprised of four levels (tiers) of increasing investigative intensity which generate information to assist in making contaminant-related determinations. Tiers I and II use existing or easily acquired information and apply relatively inexpensive and rapid tests to predict environmental effects. Tiers III and IV contain biological evaluations which are more intensive and require field sampling, laboratory testing, and rigorous data analysis.

2.1 This Manual is Intended to Address:

- contaminant-related impacts associated with discharges of dredged material (resulting from navigational dredging or dredging activities of essentially the same character as navigation dredging, such as open water discharges of dredged material excavated from a soft-bottom flood control channel or reservoir) in open water disposal areas, including wetlands.

- contaminant-related impacts to waters of the U.S. associated with dredged material runoff from confined disposal areas. Guidance on evaluation of such discharges is provided in Appendix B.

2.2 This Manual is Not Intended to Address:

- impacts associated with the dredging activity itself.

- impacts associated with dredged material discharges associated with excavation of drainage ditches and landclearing.

- impacts associated with the discharge of fill material. However, where dredged material associated with navigational dredging will be discharged in open water as fill, the procedures of this manual are applicable.

- microbiological impacts except for impacts in conjunction with the State designated use of a waterbody and human health considerations. The manual provides a list of applicable references, as the technology for analyzing other potential impacts from microorganisms (e.g., modeling potential pathways of contamination) is in various stages of development. Although scientifically accepted mechanisms for predicting the degree of potential microbiological impacts are not yet available, site management techniques are available (but are beyond the scope of this manual) to address potential impacts (e.g., aerating dredged material to kill anaerobic organisms).

2.3 Dredged Material Discharge for Beneficial Uses

The testing procedures in this manual should also be applied when navigational dredged material is proposed for certain beneficial uses. To the extent that dredged material will be discharged into open water in conjunction with a beneficial use and the evaluation of its suitability requires analysis of contaminant-related impacts listed in 2.1, the testing protocols of this manual should be applied. However, other evaluations may be necessary, in addition to those in this manual, to assess the potential for contaminant-related impacts through pathways other than those provided by open water. For example, contaminants in dredged material proposed for wetlands creation which will not adversely affect the open water environment, may be taken up by wetlands vegetation, thereby requiring evaluations that are not detailed in this manual.

This manual may also apply to dredged material used for beach nourishment. Beach nourishment normally involves hydraulic or mechanical placement of uncontaminated materials near a shoreline. As with other beneficial uses, dredged material proposed for beach nourishment often can be excluded from chemical or biological testing; the focus is on analysis to determine physical compatibility as measured by grain size and total organic carbon (see Section 9.1). However, if there is a reason to believe that contaminants are present, further evaluation should be performed.

2.4 The Role of Biological Evaluations (Toxicity and/or Bioaccumulation Tests) in the Manual

As noted in Section 230.61 of the Guidelines, the evaluation process will usually entail investigation of potential biological effects, rather than merely chemical presence, of the possible contaminants. Biological evaluations serve to integrate the chemical and biological interactions of the suite of contaminants which may be present in a dredged material sample, including their availability for biological uptake, by

measuring their effects on test organisms. Within the constraints of experimental conditions and the end-points of effects measured, biological evaluations provide for a quantitative comparison of the potential effects of a dredged material when compared to reference sediments. Thus, a specified level of change compared to reference conditions and a statistically significant result in this comparison indicate that the discharge of the dredged material in question may cause a direct and specific biological effect under test conditions and, therefore, has the potential to cause an ecologically undesirable impact. Guidance for the conduct of biological tests is given in Sections 11 and 12.

Dredged material potentially contains a myriad of chemical contaminants which may adversely impact aquatic organisms. The literature is replete with examples where aquatic organism sensitivity varies with the type of contaminant (e.g., see Rand and Petrocelli, 1985) and, as a result, a suite of aquatic species are routinely recommended to fully assess the impact of contaminants on a biological community. In this manual, three sensitive species are recommended for the water column and whole sediment toxicity tests. In the case of the latter, two species can be used, provided they cover three functional characteristics: filter feeder, deposit feeder, burrower. In both cases, at least one of these species must be a sensitive "benchmark" species. For assessing bioaccumulation, adequate tissue biomass and the ability to ingest sediments is more important than taxon sensitivity. Where possible, two species should be used to assess potential bioaccumulation unless adequate regional data are available to justify single species testing.

It is important to recognize that dredged material bioassays (toxicity and bioaccumulation tests) are subject to interpretation and are not precise predictors of environmental effects. This manual does not provide quantitative guidance on interpreting the ecological meaning of such effects (e.g., the ecological consequences of a given tissue concentration of a bioaccumulated contaminant or the consequences of that body burden to the animal). Rather, the manual considers statistically significant increases above certain levels compared to the reference sediment as potentially undesirable. Because a statistically significant difference is not a quantitative prediction that an ecologically important impact would occur in the field or vice versa, this manual discusses additional factors to be weighed in evaluating potential ecological impact. This is more likely to result in environmentally sound evaluations than is reliance on statistical significance alone.

Bioaccumulation evaluations indicate biological availability of contaminants in dredged material, which may bioaccumulate and bioconcentrate in (or, for a few chemicals, biomagnify up) aquatic food webs to levels which might be harmful to consumers, including human beings, without killing the intermediate organisms. To use bioaccumulation data, it is necessary to predict whether there will be a cause-and-effect relationship between the animal's exposure to dredged material and a meaningful adverse elevation of body burden of contaminants above that of similar animals not exposed to the dredged material.

2.5 The Role of Water and Sediment Chemical Evaluations in the Manual

Chemical evaluations of water and sediments are conducted for the following reasons:

- to determine contaminant concentrations in the dredged material
- to determine contaminant concentrations in the discharge or reference sites
- to determine compliance with water quality standards (WQS).

Chemical evaluations may be made on the basis of previous chemical inventories, when there is a reason to believe that the dredged material contains no new contaminants, or that there is no difference between contaminants in the dredged material and the disposal site [Tier I; Section 230.60(a)-(c) of the Guidelines]. The latter may be the case where the discharge site is adjacent to the dredging site, and potential differences in contaminant bioavailability are considered unlikely. There may, however, be concern with potential water column effects which would warrant evaluation of such potential effects (Tier II; Section 2.6). In particular, it must be shown that unacceptable levels of dissolved and suspended contaminants from the discharge either will not be released and transported to less contaminated areas, or can be managed.

Initial evaluation of water column chemistry may be carried out through the use of a numerical dispersion model based on bulk sediment chemistry (Section 5.1.1). If this model indicates the potential for adverse effects, a chemical evaluation of potential water column effects may be conducted through the use of elutriate tests [Tier II; Section 230.61(b)(2) of the Guidelines]. In this procedure an aqueous extract (i.e., an elutriate) is prepared from the material to be discharged, and the dissolved contaminants are compared to water quality standards with consideration of mixing. This comparison requires that dissolved contaminants in reference water (ambient condition) also be analyzed.

The above elutriate test is used to determine compliance with WQS with consideration of mixing. The elutriate test provides an indirect evaluation of potential biological effects, because WQS are derived from toxicity tests of solutions of various contaminants. Even if WQS are met, biological evaluations (see Section 2.4) must be considered.

2.6 Water Column Effects

The dredged material impact in the water column must be within the available WQS for all contaminants of concern outside of the mixing zone. If disposal operations result in long-term exposures, compliance with chronic aquatic and/or human health standards should be evaluated. Wildlife standards, if available, should also be considered. Water column toxicity tests are used to provide information on the toxicity

of contaminants not included in water quality standards, and also to indicate possible interactive effects of multiple contaminants.

2.7 Mixing

Appendix C describes the method to be used for estimating the effect of mixing for water column evaluations. 40 CFR 230.11(f)(2) describes the factors to be considered in defining mixing zones; States may use additional factors in such definition. This method is applied in evaluating the potential for impacts of the portion of dredged material that remains in the water column; all water quality and water column toxicity data must be interpreted in light of mixing [Section 230.61 (b)(2)(ii) of the Guidelines]. This is necessary because biological effects (which are the basis for WQS) are a function of the biologically available contaminant concentration and exposure time of the organisms. Laboratory toxicity tests expose organisms to specific concentrations for fixed periods of time, whereas in the field both concentration and exposure time to contaminants change continuously due to mixing and dilution. Both factors interact to control the degree of biological impact. Thus, it is necessary to incorporate the mixing expected at the discharge site into the interpretation of data.

2.8 Benthic Effects

Generally, the greatest potential for environmental effects from dredged material discharge lies in the benthic environment. Deposited dredged material is not mixed and dispersed as rapidly or as greatly as the portion of the material that may remain in the water column, and bottom dwelling animals living and feeding on deposited material for extended periods represent the most likely pathways by which adverse effects to aquatic biota can occur. Therefore, the major evaluative effort must be placed on deposited material and the benthic environment, unless there is a compelling reason to do otherwise. The approach in this manual is conservative (i.e., protective) as it uses whole-sediment bioassays (toxicity and bioaccumulation tests) to evaluate the solid phase of the dredged material. Sediment chemical analyses currently cannot be used to directly evaluate the biological effects of any contaminants which may be present in dredged material because such potential effects are a function of bioavailability. However, as noted in Section 2.5, there are circumstances where it may be reasonably assumed that bioavailability in the dredged material and the discharge site are similar. When decisions cannot be made using evaluations in Section 230.60 of the Guidelines, bioaccumulation tests should be used to directly determine the bioavailability of potential contaminants.

2.9 Management Options

Some dredged material evaluated in accordance with technical procedures in this manual may demonstrate

a potential for unacceptable environmental impacts or not meet Federally approved State WQS. If so, a careful case-by-case evaluation of management options (e.g., alternative dredging and discharge methods, alternative discharge sites, confined disposal, capping, site controls such as covers and/or liners) will be necessary to determine whether the proposed discharge can be made acceptable or can be brought into compliance with the Guidelines and State WQS. As previously noted, it is beyond the scope of this manual to determine whether a material which would not otherwise comply with the Guidelines, could be brought into compliance through appropriate management actions or other discharge methods.

2.10 The Relationship of the Inland Testing Manual to Other USACE/EPA Dredged Material Management Efforts

2.10.1 Relationship of the Manual to the USACE/EPA Framework Document

EPA and USACE have long recognized the need for a consistent technical framework for decision-making regarding the discharge of dredged material in ocean, near coastal, and inland waters (e.g., see Francingues et al., 1985; Wright and Saunders, 1990). This manual is one of a series of guidance documents jointly developed by EPA and the USACE in response to that recognition. This series of guidance documents includes the "Evaluating Environmental Effects of Dredged Material Management Alternatives - A Technical Framework" (USACE/EPA, 1992) which articulates those factors (including the potential for and degree of contaminant-related impacts) to be considered in identifying the environmental effects of dredged material management alternatives on a continuum from uplands to oceans, and which meet the substantive and procedural requirements of NEPA, CWA and MPRSA. The companion testing manual for ocean disposal, the Green Book (EPA/USACE, 1991) is included in the series. Application of the testing guidance in this manual within the context of the Framework Document will allow for consistency in decision-making with respect to technical considerations, across statutory boundaries and with consideration of the continuum of dredged material discharge options.

2.10.2 Relationship of the Manual to the EPA/USACE Green Book

Although the Ocean Dumping and the CWA programs carry out their functions under different mandates and different environments (estuarine, lake and riverine *versus* ocean), there is a considerable overlap in terms of practical application. The Guidelines are statutorily directed to be based upon criteria comparable to those developed under Section 403(c) for the territorial seas, contiguous zone, and ocean. Additionally, in previous guidance both EPA and USACE have acknowledged the ecological similarity of all aquatic areas and the need for a consistent technological analysis framework, particularly when the waters of the

United States under consideration for a discharge are near-coastal. While details of this manual are necessarily different from one addressing only ocean waters, the tiered testing framework and concepts of the Green Book are an appropriate paradigm. The Inland Testing Manual also utilizes the Green Book's reference site approach which provides a more accurate data base for cumulative impact analysis.

Dredged material transported for purposes of dumping or disposal seaward of the baseline of the territorial sea will continue to be regulated under the MPRSA (commonly referred to as the Ocean Dumping Act). MPRSA-regulated dredged material disposal will be tested in accordance with procedures outlined in the Green Book (EPA/USACE, 1991). As previously discussed, dredged material used as fill within the territorial sea, such as for beach nourishment, is regulated under the CWA and will be tested in accordance with this manual.

2.10.3 Relationship of the Manual to EPA's Contaminated Sediment Strategy and Sediment Quality Criteria

EPA is developing a Contaminated Sediment Management Strategy (Strategy; Southerland et al., 1992) which is a multi-program effort to address contaminated aquatic sediments in the United States. The Strategy is intended to improve the understanding of the extent and severity of sediment contamination and to propose prevention, control, and remediation programs. The Strategy describes the policy framework and specific actions EPA could take to promote the consideration of and reduction of ecological and human health risks posed by sediment contamination. The Strategy also recommends a comprehensive research program and outreach activities with other agencies and the general public.

One component of the Strategy is the development of Sediment Quality Criteria (SQC), which are derived numerical values representing the concentration of chemicals in sediment which are determined to adversely affect benthic organisms. SQC are included in EPA's approach to defining contamination in sediments, and are envisioned to play a range of roles in all programs, from assessment to remediation. When finalized, SQC likely will be incorporated into the Inland Testing Manual in Tier II. SQC could also form the basis for State SQS. The Inland Testing Manual is structured such that evolving science may be readily merged into the document.

PART II - EVALUATION OF POTENTIAL ENVIRONMENTAL IMPACT

3.0 OVERVIEW OF TESTING AND EVALUATION

As noted in Section 1.2.2.1, conclusions reached utilizing this manual will be used to make factual determinations of the potential effects of a proposed discharge of dredged material on the physical, chemical and biological components of the aquatic environment. Such factual determinations are used to make findings of compliance or noncompliance with relevant parts of Sections 230.10(b) (including compliance with established water quality standards) and 230.10(c) (determinations of potential contaminant-related impacts to aquatic resources).

3.1 Tiered Testing and Evaluation

The tiered approach to testing used in this manual must be initiated at Tier I. It is designed to aid in generating physical, chemical, toxicity and bioaccumulation information, but not more information than is necessary to make factual determinations. This allows optimal use of resources by focusing the least effort on disposal operations where the potential (or lack thereof) for unacceptable adverse impact is clear, and expending the most effort on operations requiring more extensive investigation to determine the potential (or lack thereof) for impact. To achieve this objective, the procedures in this manual are arranged in a series of tiers, or levels of intensity (and cost) of investigation. Tiered testing results in environmental protection in the context of more efficient completion of necessary evaluations and reduced costs, especially to low-risk operations. Disposal operations that obviously have low environmental impact generally should not require intensive investigation to make factual determinations. Evaluation at successive tiers is based on more extensive and specific information about the potential impact of the dredged material, that may be more time-consuming and expensive to generate, but that allows more and more comprehensive evaluations of the potential for environmental effects. At any tier except for Tier IV, failure to satisfactorily determine the potential for unacceptable aquatic environmental impact, or to develop sufficient information to make factual determinations, results in additional testing at a subsequent, more complex tier unless a decision is made to seek other disposal alternatives (thereby avoiding the potential for unacceptable aquatic environmental impacts).

It is necessary to proceed through the tiers only until information sufficient to make factual determinations has been obtained. For example, if the available information is sufficient to make factual determinations, no further testing is required.

The initial tier (Tier I) uses readily available, existing information (including all previous testing). For certain dredged materials with readily apparent potential for environmental impact (or lack thereof), information collected in Tier I may be sufficient for making factual determinations. However, more

extensive evaluation (Tiers II, III and IV) may be needed for other materials with less clear potential for impact or for which Tier I information is inadequate.

Tier II is concerned solely with sediment and water chemistry. Tier III is concerned with well-defined, nationally accepted toxicity and bioaccumulation testing procedures. Tier IV allows for case-specific laboratory and field testing, and is intended for use in unusual circumstances.

The approach is to enter Tier I and proceed as far as necessary to make factual determinations. Although it is not always necessary that all dredged material be evaluated through all tiers, there must be enough information available to make determinations on all aspects of the Guidelines relating to water column impact, benthic toxicity and benthic bioaccumulation. It is acceptable to carry water-column and benthic evaluations, or toxicity and bioaccumulation evaluations, to different tiers to generate the information necessary and sufficient to make these determinations.

Prior to initiating testing, it is essential that the informational requirements of preceding tiers be thoroughly understood and that the information necessary for interpreting results at the advanced tier be assembled. For example, it is always appropriate to gather all relevant available information and identify the chemicals of concern for the dredged material in question even though it may be clear without formal Tier I evaluation that further assessment will be necessary.

The tests in this manual reflect the present state-of-the-art procedures for dredged material evaluation. However, it is recognized that the evaluation of dredged material is an evolving field. It is anticipated that, as new methods of evaluation are developed and accepted, they will be integrated into the tiered framework. The tiered approach will be maintained because of the efficiency afforded by its hierarchical design.

The tiered approach used in the manual is summarized in Figure 3-1, and additional detail on water column and benthic evaluation is presented in Figures 3-2 and 3-3. These flowcharts should be used in conjunction with a careful reading of the corresponding guidance presented in this manual, in particular Sections 4, 5, 6 and 7. The sections or figures in the manual that present the technical guidance shown by the flowcharts are indicated in the boxes on the figures.

3.2 Control and Reference Sediments

It is important to clearly distinguish between control and reference sediments in the context of testing for benthic impacts. In general, control sediment is that within which the organisms resided prior to

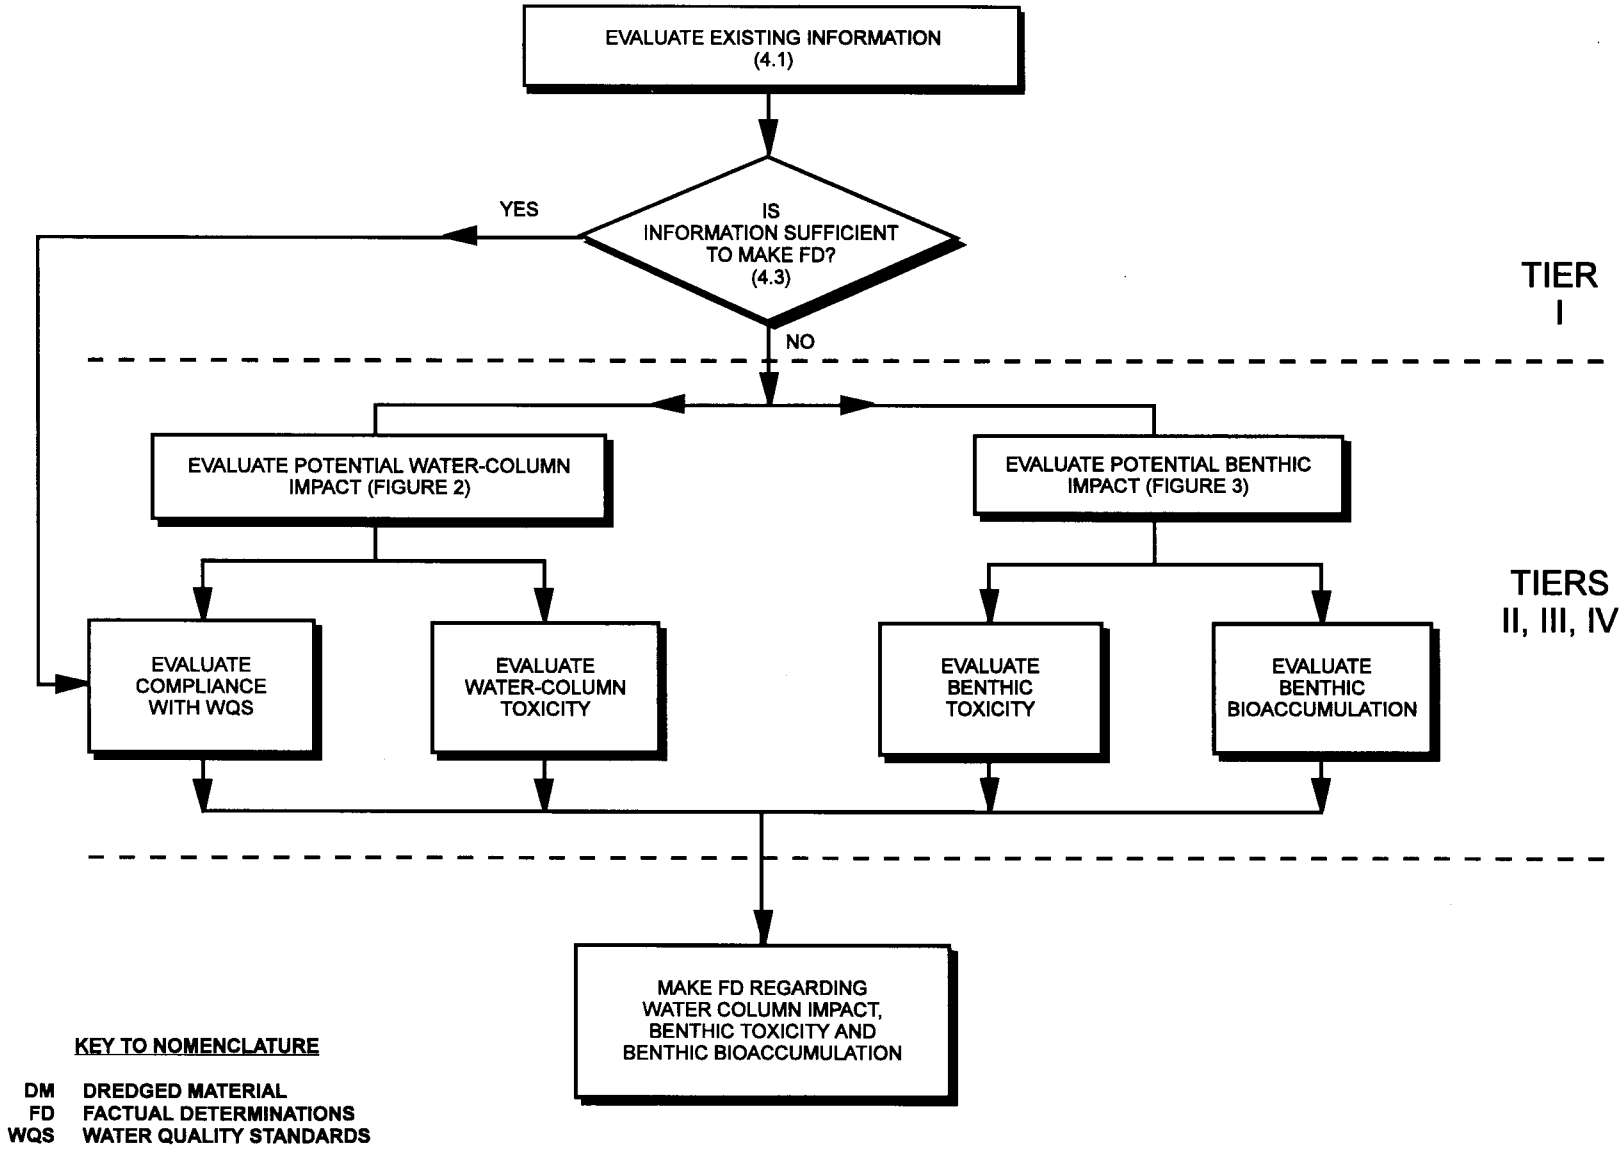

Figure 3-1. Simplified Overview of Tiered Approach to Evaluating Potential Impact of Aquatic Disposal of Dredged Material.

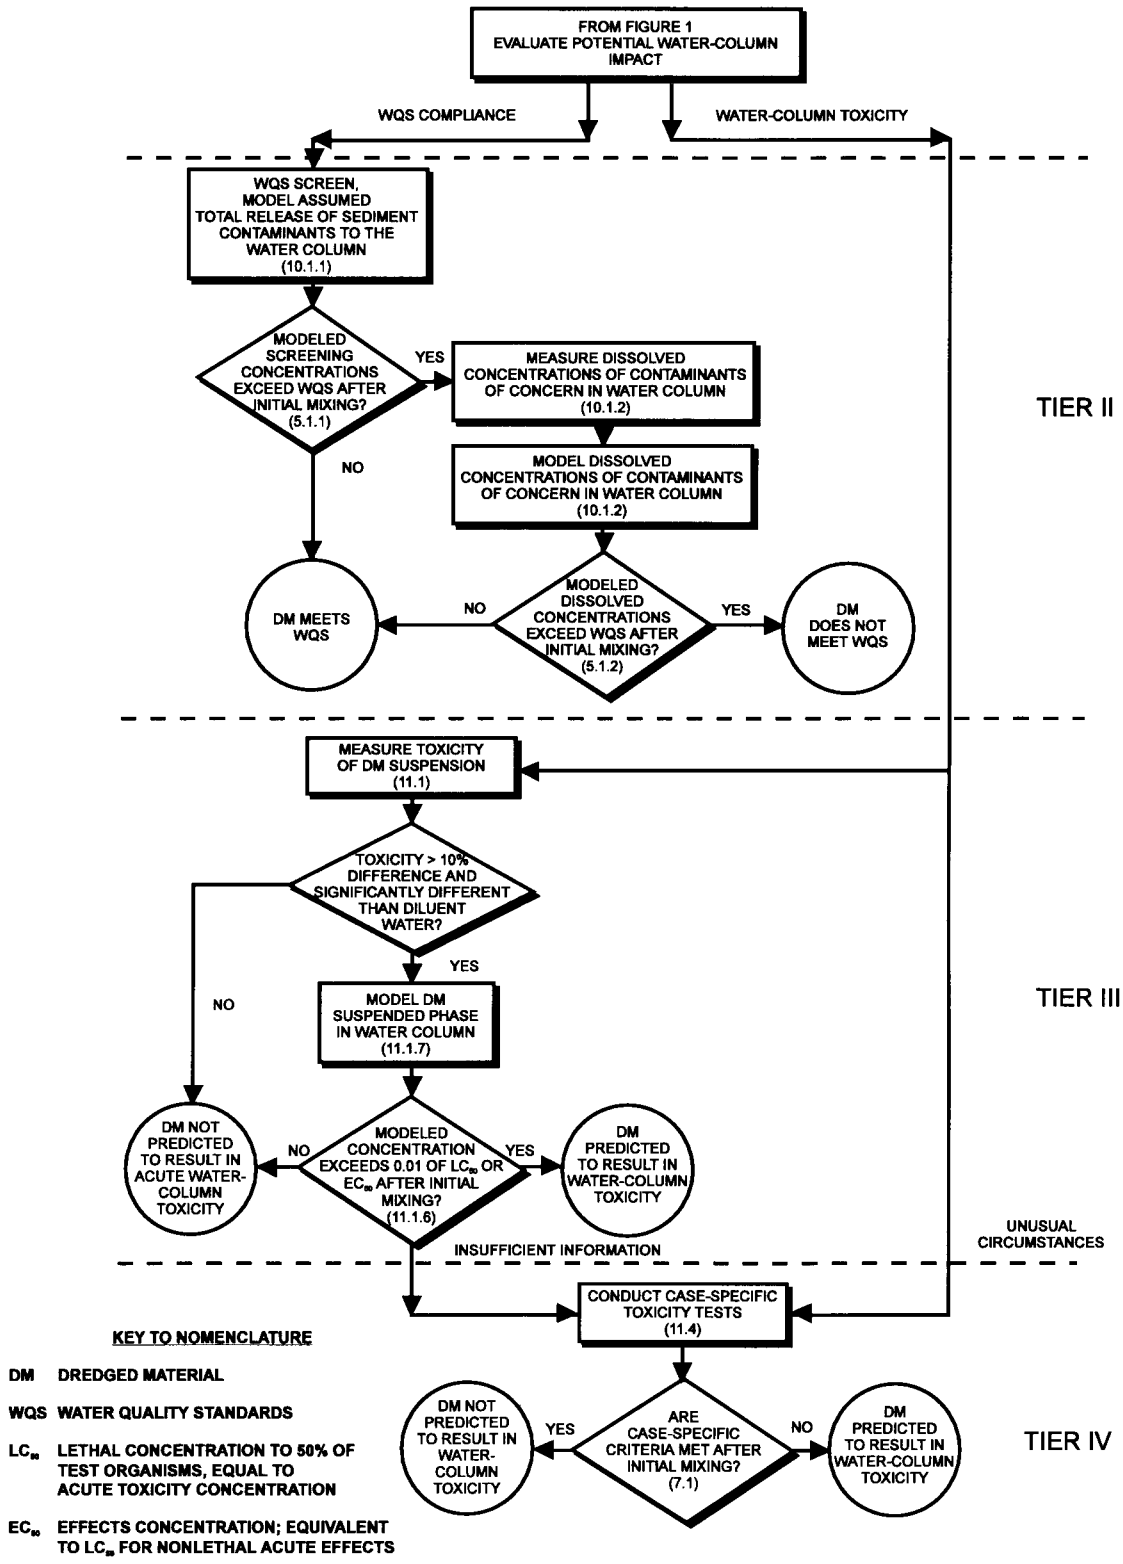

Figure 3-2. Illustration of Tiered Approach to Evaluating Potential Water Column Impacts of Dredged Material.

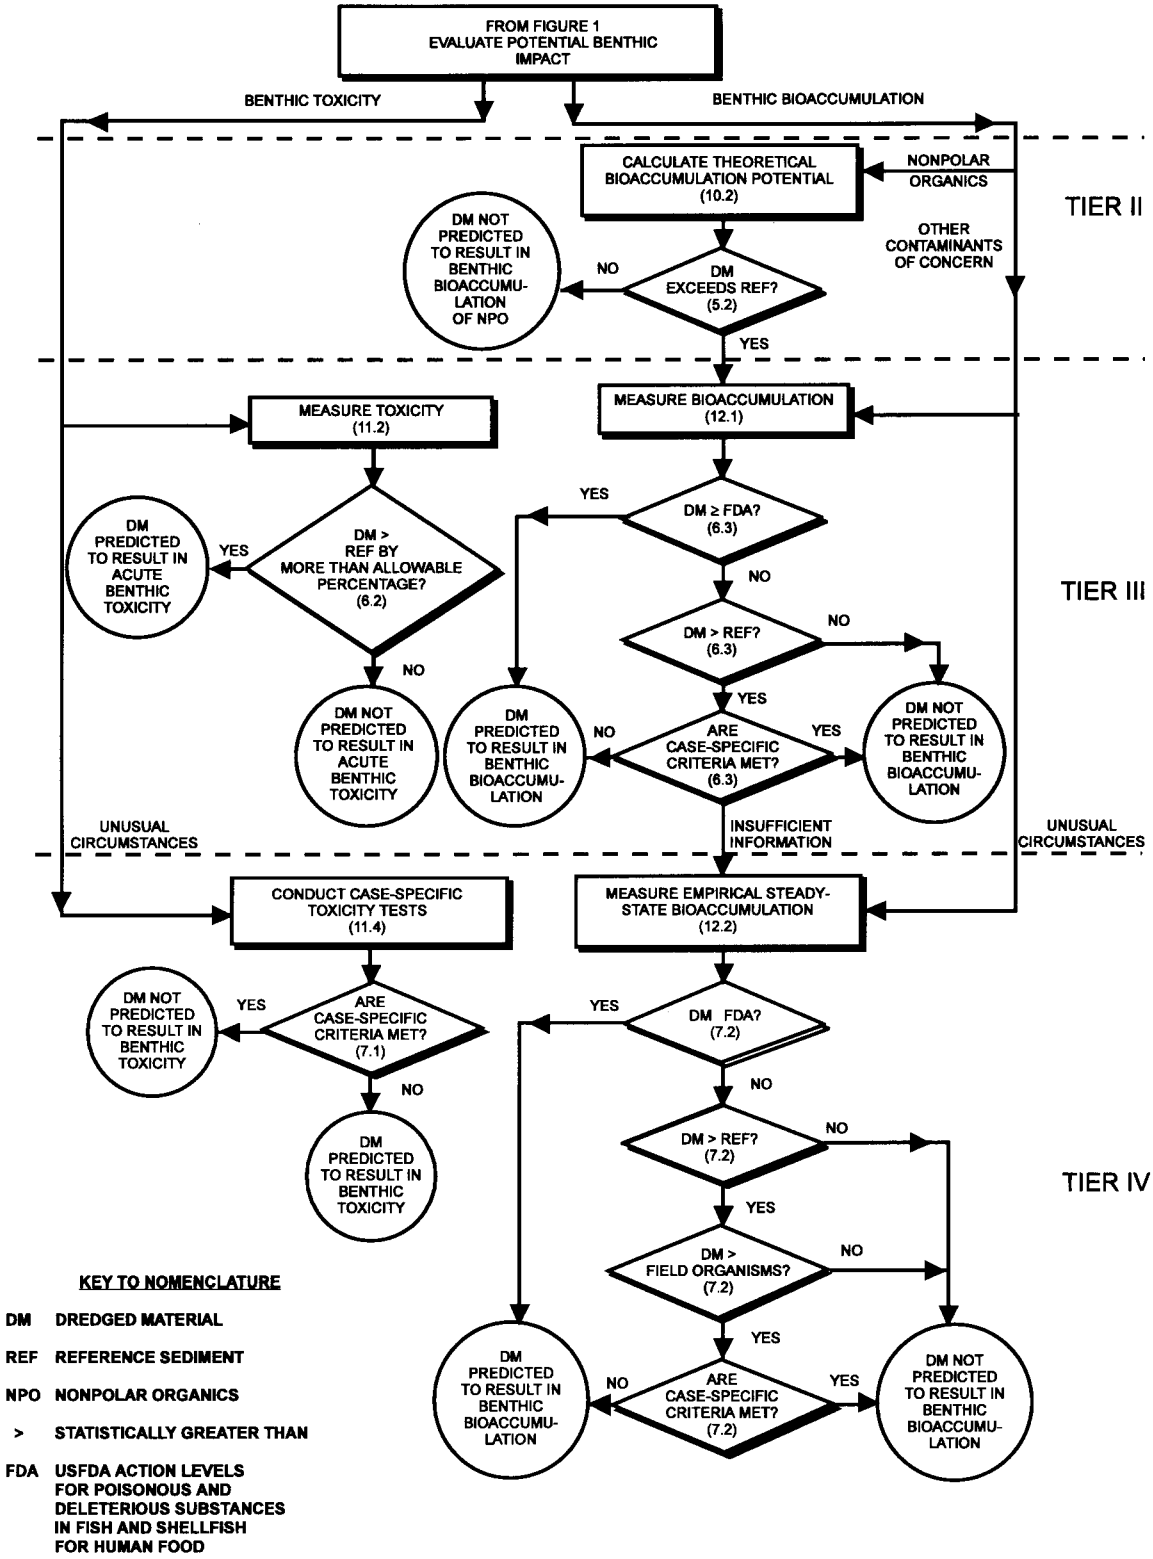

Figure 3-3. Illustration of Tiered Approach to Evaluating Potential Benthic Impacts of Deposited Dredged Material.

collection in the field or is that within which they were cultured in the laboratory, and serves to confirm the health of the test animals and the acceptability of the test conditions. Generic control sediments are also possible and consist of field-collected or laboratory prepared sediment. Reference sediment is the key to the evaluation of dredged material. Results of tests using reference sediment provide the point of comparison (reference point) to which benthic effects of dredged material are compared.

In some cases, it may be appropriate to use more than one reference sediment for a single dredging project. This could occur when the dredged material or the disposal site has a wide range of grain-sizes or TOC, when management needs suggest that disposal of different dredged materials at different locations in the disposal site is desirable, or when discharge at more than one site is being considered. One reference site can serve more than one disposal site.

3.2.1 Reference Sediment Sampling

Reference sediment is the point of comparison for evaluating test sediment. Testing requirements in the Section 404(b)(1) Guidelines regarding the point of comparison for evaluating proposed discharges of dredged material are being updated to provide for comparison to a "reference sediment" as opposed to sediment from the disposal site. Because subsequent discharges at a disposal site could adversely impact the point of comparison, adoption of a reference sediment that is unimpacted by previous discharges of dredged material will result in a more scientifically sound evaluation of potential individual and cumulative contaminant-related impacts. This change to the Guidelines was proposed in the Federal Register in January 1995, public comments have been received, and a final rule Notice is being prepared. It is expected that the final rule will be published prior to July 1, 1998, and as a result the reference sediment approach will be implemented in the ITM.

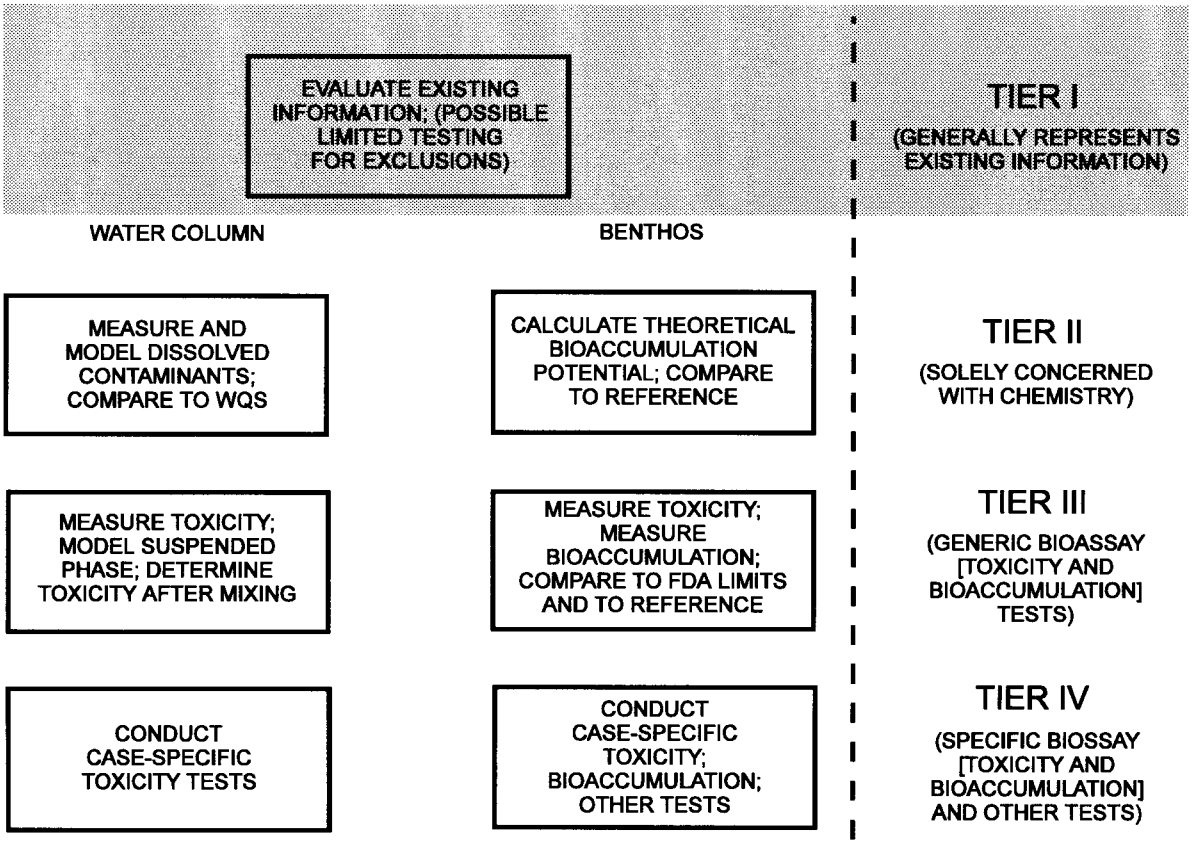
Reference sediment is generally collected outside the influence of previous disposal operations at a dredged material disposal site, but near enough to the disposal site that the reference sediment is subject to all the same influences (except previously disposed dredged material) as the disposal site. If there is a potential for sediment migration or there is a reason to believe that previously disposed sediment has migrated, reference sediment should be collected from an area that is not expected to be influenced by test material. There are four potential reference sampling approaches as discussed below. We recommend the first two reference approaches because they allow statistically valid comparisons.

Reference Point Approach: This approach is used when the disposal site is known to be sufficiently homogeneous that a single reference location is representative of the disposal site. A single reference location is sampled and the sediment is tested concurrently with the dredged material. The bioassay results from the reference sediment are statistically compared to those obtained from benthic toxicity and bioaccumulation tests of the material to be dredged.

Reference Area Approach: This approach is used when the disposal site is known to be heterogeneous and more than one reference location must be sampled to adequately characterize the disposal site. Several reference locations are sampled and a composite of all of the sediments are tested concurrently with the dredged material. The bioassay results from the reference sediment composite are statistically compared to those obtained from benthic toxicity and bioaccumulation tests of the material to be dredged.

Periodic Reference Point Approach: This approach could, theoretically, be used when it is not desirable or possible to sample the reference location each time that dredged material is to be tested. Values from the homogeneous reference location collected over a period of time are used to develop decision guidance values which are compared to those obtained from benthic toxicity and bioaccumulation tests of the material to be dredged.

Periodic Reference Area Approach: This approach could, theoretically, be used when it is not desirable or possible to sample the heterogeneous reference locations each time that dredged material is to be tested. Values from heterogeneous reference locations collected over a period of time are used to develop decision guidance values which are compared to those obtained from benthic toxicity and bioaccumulation tests of the material to be dredged.



Appendix D, Statistical Methods, provides guidance for conducting statistical comparisons for the reference point and reference area approaches. It does not provide guidance for the use of either of the "periodic" approaches.

3.2.2 Reference Sediment Sampling Plan

The importance of thoughtful selection of the reference sampling approach cannot be overemphasized. To ensure that an appropriate approach is used, information gathered during the site specification process or other studies should be consulted for both the disposal and the reference sites. In some instances there are differences in the statistical methods used in comparing results from the various reference sampling methods to those obtained from the dredged material being

evaluated. There may also be differences in costs among the approaches. Prior to selecting an approach, it is imperative that Appendix D be consulted to determine which approach best fits specific concerns and conditions, including feasibility, technical validity, and cost.

A well-designed sampling plan is essential to the collection, preservation, and storage of samples so that potential toxicity and bioaccumulation can be accurately assessed (Section 8). The implementation of such a plan is equally essential for dredged material, control sediment, and reference sediment.

4.0 TIER I EVALUATION

One of the purposes of Tier I is to determine whether factual determinations can be made on the basis of existing information. Tier I is a comprehensive analysis of all existing and readily available, assembled, and interpreted information on the proposed dredging project, including all previously collected physical, chemical, and biological monitoring data and testing for both the dredged material excavation site and the proposed disposal site. Only limited testing, to determine the applicability of exclusions, may be necessary in this tier.

If the information set compiled in Tier I is adequate to meet the exclusions or is complete and comparable to that which would satisfy Tier II, III, or IV, as appropriate, factual determinations can be made without proceeding into the higher tiers (Figure 3-1). For an evaluation to be completed within Tier I, the burden of evidence of the collected information must be adequate to make factual determinations.

The initial focus of the Tier I evaluation is on information relevant to Sections 230.60 (a), (b), (c), and (d) of the Guidelines and the potential for contaminant-associated impacts upon discharge. These four sections of the Guidelines fully define the exclusions from testing, which are summarized below.

If an evaluation of the dredging site indicates that the dredged material is not a "carrier of contaminants", testing may not be necessary. Such situations are most likely to arise if: the dredged material is composed primarily of sand, gravel and/or inert materials; the sediments are from locations far removed from sources of contaminants; the sediments are from depths deposited in preindustrial times and not exposed to modern sources of pollution. However, potential impacts from natural mineral deposits must also be considered.

Testing may also not be necessary "where the discharge site is adjacent to the excavation site and subject to the same sources of contaminants, and materials at the two sites are substantially similar "(Section 230.60 (c)). However, some physical and chemical testing may be necessary to confirm that the two sites are "substantially similar". The rationale behind this exclusion from testing is that when 1) the discharge and excavation sites are adjacent, 2) the concentration of contaminants in the two sites are not substantially different, and 3) the geochemical environments are similar, then the bioavailability of contaminants at the two sites are likely to be similar. This exclusion can apply even if the dredged material is a carrier of contaminants, providing that "dissolved materials and suspended particulates can be controlled to prevent carrying pollutants to less contaminated areas".

Section 230.60 (d) states that testing may not be necessary with material likely to be a carrier of contaminants if constraints acceptable to the USACE District Engineer and EPA Regional Administrator

are available to "reduce contamination to acceptable levels within the disposal site and to prevent contaminants from being transported beyond the boundaries of the disposal site". Such constraints may involve technologies such as capping and underwater containment. Design and monitoring requirements for such constraints should be determined by the Regional Administrator and District Engineer on a case-by-case basis.

If the exclusionary criteria are satisfied, factual determinations for the dredged material can be made and no further evaluation is necessary. If the exclusionary criteria are not met, the material is evaluated based on all existing information. This information should include chemical information and, if appropriate, existing data on the toxicity and bioaccumulation potential of the dredged material and of the reference sediment. The information must be sufficient to determine if water quality standards are met and, if appropriate, whether 1% of the LC_{50} or EC_{50} of each tested species will or will not be exceeded in the water column following mixing. If adequate information is not available for a Tier I evaluation, the process moves to Tier II.

Even if factual determinations cannot be made on the basis of Tier I information, the information collected can be put to use in later tier analyses. Another purpose of Tier I is to identify the contaminants of concern (if any) in the dredged material. This information is used to select analyses in Tiers II, III, and IV. Similarly, other information collected in Tier I may be used to satisfy all or portions of evaluations in other tiers. It is necessary to proceed through the tiers only until a factual determination is reached. Rigorous information collection and assessment in Tier I inevitably saves time and resources in making final determinations.

Annual or episodic dredging, undertaken to maintain existing navigation improvements, may warrant a periodic Tier I reevaluation. The general recommendation of EPA and USACE is that the interval between reevaluation of Tier I data for these projects not exceed three years or the dredging cycle, whichever is longest. If there is reason to believe that conditions have changed, then the time interval for reevaluation may be less than three years. As a minimum, this reevaluation should include a technical reassessment of all new and previously evaluated physical, chemical and biological data, changes in sediment composition or deposition (e.g., industrial development in the watershed), improvements in analytical methods and contaminant detectability, quality assurance considerations and any regulatory changes.

4.1 Compilation of Existing Information

The potential for contaminants to have been introduced to the dredged material, evaluated with consideration of the physical nature of the dredged material, and the proposed disposal site, allows case-by-case determinations of whether the proposed discharge of dredged material may result in contamination, bioaccumulation or toxicity above reference levels. Section 230.60 (b) of the Guidelines lists a number of factors which should be considered when evaluating the potential for contamination at the dredging (i.e., extraction) site. These factors represent sources of contamination, pathways of contaminant transport, and naturally occurring substances which may be harmful to aquatic biota:

- urban and agricultural runoff
- sewer overflows/bypassing
- industrial and municipal wastewater discharges
- previous dredged or fill discharges
- landfill leachate/groundwater discharge
- spills of oil or chemicals
- releases from Superfund and other hazardous waste sites
- illegal discharges
- air deposition
- biological production (detritus)
- mineral deposits.

The information gathering phase of Tier I evaluations has to be as complete as is reasonably possible, including existing information from all reasonably available sources. This will increase the likelihood that determinations concerning the impact of dredged material may be made at initial tiers. Sources of available information include the following, without limitation:

- Results of prior physical, chemical, and biological tests and monitoring of the material proposed to be disposed.
- Information describing the source of the material to be disposed which would be relevant to the identification of potential contaminants of concern.
- Existing data contained in files of agencies such as EPA or USACE or otherwise available from public or private sources. Examples of sources from which relevant information might be obtained include:
    - Selected Chemical Spill Listing (EPA)
    - Pesticide Spill Reporting System (EPA)
    - Pollution Incident Reporting System (United States Coast Guard)

- Identification of In-Place Pollutants and Priorities for Removal (EPA)
- Hazardous waste sites and management facilities reports (EPA)
- USACE studies of sediment pollution and sediments
- Federal STORET, BIOS, CETIS, and ODES databases (EPA)
- Water and sediment data on major tributaries (Geological Survey)
- NPDES permit records
- Agencies with contaminant or related information, for instance, Fish and Wildlife Service (FWS), National Oceanic and Atmospheric Administration (NOAA), regional planning commissions, state resource/survey agencies
- CWA 404(b)(1) evaluations
- Pertinent and applicable research reports
- MPRSA 103 evaluations
- Port and marina authorities
- Colleges/Universities
- Records of State agencies, (e.g., environmental, water survey, transportation, health)
- Superfund sites, hazardous waste sites
- Published scientific literature.

Sources may contribute differing types and quantities of contaminants to sediments. For example, a matrix of potential correlations between industrial sources and specific contaminants is provided in Table 4-1. This matrix is, however, not all inclusive and makes no accounting for current pollution control practices.

There are also a number of factors which influence the pathways between contaminant sources and the dredging and disposal sites, including:

- bathymetry
- water current patterns
- tributary flows
- watershed hydrology and land uses
- sediment and soil types
- sediment deposition rates.

More detailed site-specific guidance for reaching administrative decisions concerning the impact of a dredged material discharge may be developed by particular EPA Regions and USACE Districts by considering available scientific information and locally important concerns. In evaluating the likelihood

that discharge of a dredged material may cause contaminant associated impacts, concern decreases with the increase of factors such as:

- isolation of the dredging operation from known existing and historical sources of contamination
- time since historical sources of contamination have been remediated
- number and frequency of maintenance dredging operations since abatement of the source of contamination
- mixing and dilution occurring between the contamination source and the dredging site
- transport and potential deposition of sediment in the dredging area from sources other than those potentially affected by contamination
- grain size of the dredged material.

Concern regarding contaminant associated impacts increases with the increase of factors such as the number, amount, and toxicological importance of contaminants:

- known to have been introduced to the dredging site
- suspected to have been introduced to the dredging site
- included in continuing input from existing sources
- included in historical sources.

These and other considerations are complexly interrelated; i.e., the acceptable degree of isolation from sources of contamination depends on the number, amount, and toxicological importance of the contaminants as well as on all other factors. These considerations have to be evaluated for all dredged material. Even so, it is desirable that local guidance be developed, based on technical evaluations, that describes the emphasis on factors deemed appropriate in each area. In all cases, the decisions that are based on these factors must be compatible with the Guidelines.

4.2 Identification of Contaminants of Concern

In the Tier I decision sequence (Figure 3-1), the first possibility is that more information is required to make a factual determination. A critical prerequisite to generating this information and one which is crucial to the success of the testing program is deciding, on a case-by-case basis, which contaminants are of concern, particularly for 401 certification, in the dredged material being evaluated. To determine the contaminants of concern, it may be necessary to supplement available information with additional chemical analyses of the dredged material. Contaminants of concern are not restricted to compounds

which inhibit organisms but also those which promote undesirable organisms or growth (e.g., nutrients such as phosphorous - Nakaniski et al., 1986). However note that in at least some cases nutrient releases may be minimal and of no environmental concern (e.g., Tavolaro and Mansky, 1985).

4.2.1 Microbial Contamination

As noted in Section 2.2, this manual only addresses microbiological concerns to the extent that they address State 401 certification requirements. To this end, major areas of concern and pertinent sources of information addressing these and other relevant microbiological issues are provided below.

If sediments are suspected to have high levels of microbial contamination and dredging or disposal sites are close to shellfish beds, swimming beaches or drinking water intakes, then microbial sediment analyses may be required. Useful references include: EPA (1978); Gerba et al. (1979); Dutka et al. (1988) and Helmer et al. (1991). Appropriate state health and water quality agencies should be consulted for guidance and appropriate methods for measuring microbial contamination.

There are three major areas of concern for microbiological contamination and effects related to dredged sediments: (1) contamination of harvestable shellfish (e.g., Hood et al., 1983; Bruckhardt et al., 1992; Martinez-Manzanares et al., 1992); (2) body contact, generally related to swimming beaches (e.g., Fleisher, 1991; Helmer et al., 1991) ; (3) contamination of drinking water (e.g., Geldreich, 1991; Helmer et al., 1991). As noted in the Guidelines (e.g., 230.21, Suspended Particulates, and elsewhere), the ultimate concern is that "...pathogens and viruses...may be biologically available".

Sediments generally contain higher concentrations of indicators of fecal contamination and pathogens, such as *Salmonella* and viruses, than occur in the water column (e.g., Chen et al., 1979; Gerba et al., 1979; LaBelle et al., 1980). Further, these microorganisms survive longer in the sediments than in the water column (e.g., DeFlora et al., 1975; Smith et al., 1978; Borrego et al., 1983; Rao et al., 1984). Sediments have been shown to be a source of microorganisms released to the water column (e.g., VanDonsel and Geldreich, 1971; Shiharis et al., 1987; Hardina and Fujioka, 1991). More specifically, dredging and disposal have been shown to release these microorganisms (e.g., Grimes, 1975; Babinchak et al., 1977).

4.2.2 Chemical Contamination

Nationally, it is difficult to specify a single set of contaminants that adequately addresses all environmental concerns. However, regions may develop their own general contaminants of concern list for routine permitting purposes. In some dredged materials, there may be no contaminants of concern. Different disposal operations may have their own set of contaminants of environmental concern that should be adequately evaluated for each operation.

Identifying specific contaminants that are of concern in a particular dredged material is dependent on the information collected for Tier I. In some instances, it may be sufficient to perform confirmatory analyses for specific contaminants of concern identified in Tier I. In other cases, where the initial evaluation indicates that a variety of contaminants of concern may be present, chemical analysis of the dredged material could provide a useful inventory, and bulk sediment chemistry analysis conducted according to the guidance in Section 9.3 may be appropriate and, in fact, would be necessary to conduct the Tier II water quality screen and the theoretical bioaccumulation potential determination. Contaminants always of interest, if present, are those for which there are FDA limits or state fish advisories and where WQS exceedances exist. Other contaminants that should be included are those that might reasonably be expected to cause an unacceptable adverse impact if the dredged material is discharged.

The contaminants of concern in each dredged material should be identified on the basis of the following, keeping in mind the discussion in Sections 9.3, 9.4, and 9.5:

- presence in the dredged material
- presence in the dredged material relative to the concentration in the reference sediment
- toxicological importance
- persistence in the environment
- propensity to bioaccumulate from sediments.

  The major chemical properties controlling the propensity to bioaccumulate are:

  Hydrophobicity

  Literally, "fear of water"; the property of neutral (i.e., uncharged) organic molecules that causes them to associate with surfaces or organic solvents rather than to be in aqueous solution. The presence of a neutral surface such as an uncharged organic molecule causes water molecules to become structured around the intruding entity. This structuring is energetically unfavorable, and the neutral organic molecule tends to be partitioned to a less energetic phase if one is available. In an operational sense, hydrophobicity is the reverse of aqueous solu-

bility. The octanol/water partition coefficient (K_{ow}, log K_{ow}, or log P) is a measure of hydrophobicity. The tendency for organic chemicals to bioaccumulate is related to their hydrophobicity. Bioaccumulation factors increase with increasing hydrophobicity up to a log K_{ow} of about 6.00. At hydrophobicities greater than about log K_{ow} = 6.00, bioaccumulation factors tend not to increase due, most likely, to reduced bioavailability.

Aqueous Solubility

Chemicals such as acids, bases, and salts that speciate (dissociate) as charged entities tend to be water-soluble and those that do not speciate (neutral and nonpolar organic compounds) tend to be insoluble, or nearly so. Solubility favors rapid uptake of chemicals by organisms, but at the same time favors rapid elimination, with the result that soluble chemicals generally do not bioaccumulate to a great extent. The soluble free ions of certain heavy metals are exceptional in that they bind with tissues and thus are actively bioaccumulated by organisms.

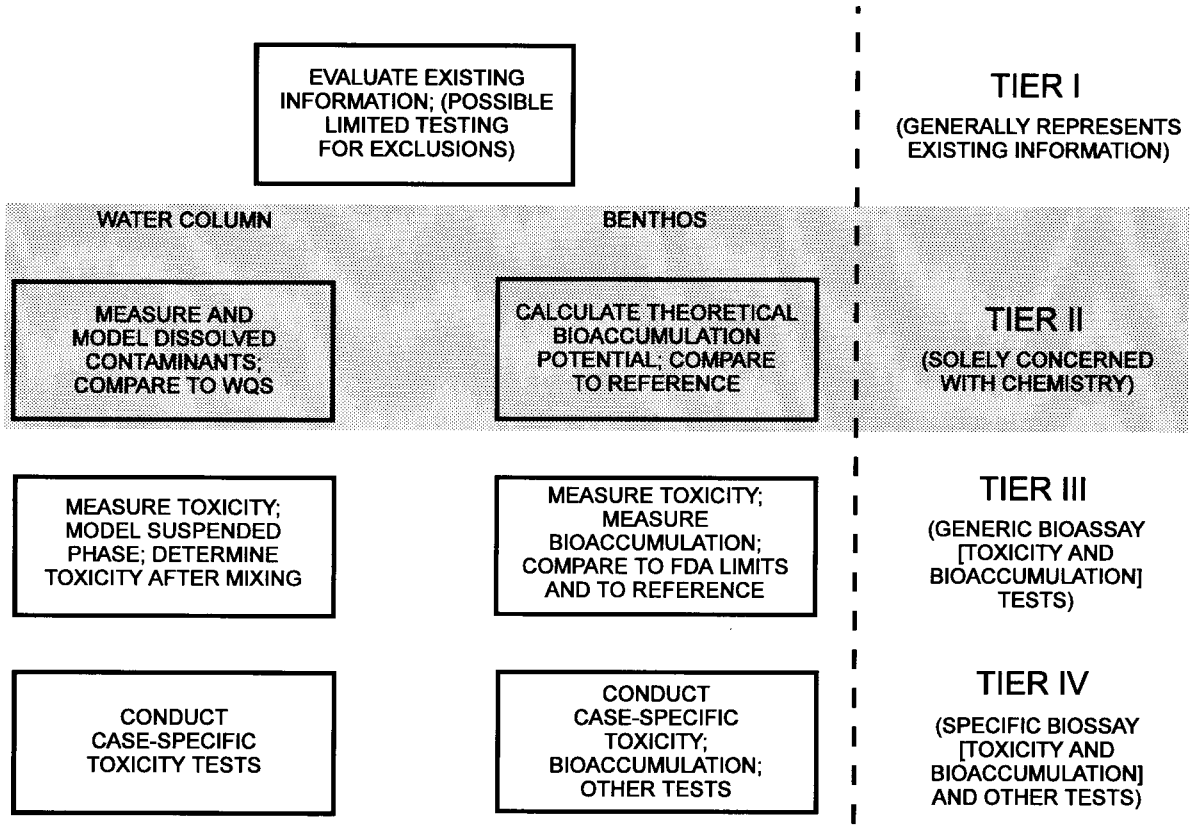
Stability

For chemicals to bioaccumulate, they must be stable, conservative, and resistant to degradation (although some contaminants degrade to other contaminants which do bioaccumulate). Organic compounds with structures that protect them from the catalytic action of enzymes or from nonenzymatic hydrolysis tend to bioaccumulate. Phosphate ester pesticides do not bioaccumulate because they are easily hydrolyzed. Unsubstituted polynuclear aromatic hydrocarbons (PAH) can be broken down by oxidative metabolism and subsequent conjugation with polar molecules. The presence of electron-withdrawing substituents tends to stabilize an organic molecule. Chlorines, for example, are bulky, highly electronegative atoms that tend to protect the nucleus of an organic molecule against chemical attack. Chlorinated organic compounds tend to bioaccumulate to high levels because they are easily taken up by organisms, and, once in the body, they cannot be readily broken down and eliminated.

Stereochemistry

The spatial configuration (i.e., stereochemistry) of a neutral molecule affects its tendency to bioaccumulate. Molecules that are planar tend to be more lipid-soluble (lipophilic) than do globular molecules of similar molecular weight. For neutral organic molecules, planarity can correlate with higher bioaccumulation unless the molecule is easily metabolized by an organism.

4.3 Tier I Conclusions



After consideration of all available information, one of the following conclusions is reached (Figure 3-1):

- Existing information does not provide a sufficient basis for making factual determinations. In this case, further evaluation in higher tiers is appropriate.

- Existing information provides a sufficient basis for making factual determinations. In this case, one of the following decisions is reached (Figure 3-1):

    - The material meets the exclusion criteria.

    - The material does not meet the exclusion criteria but information concerning the potential impact of the material is sufficient to make factual determinations.

5.0 TIER II EVALUATION

Tier II provides useful information through screening tools, but not all possible determinations can be reached at this tier. It consists of evaluation of State water quality standard (WQS) compliance using a numerical mixing model of the disposal site conditions (Figure 3-2 and Appendix C) and an evaluation of the potential for benthic impact using calculations of theoretical bioaccumulation potential (TBP) (Figure 3-3 and Section 10.2).

Tier II is ultimately expected to provide a reliable, rapid screen to determine potential dredged material contaminant effects. The dredged material discharge must meet applicable WQS for all contaminants of concern outside the mixing zone. Water column impact must also be evaluated by toxicity testing in Tier III (Figure 3-2) when there are contaminants of concern for which applicable WQS are not available or where interactive effects are of concern.

When national sediment quality criteria (SQC) are proposed and finalized they are expected to provide a basis for State sediment quality standards (SQS). State SQS will be incorporated into Tier II benthic impact evaluations. The incorporation of these standards into Tier II will be implemented in this testing manual and regional manuals as appropriate.

At present, only the bioaccumulation impact of nonpolar organic compounds in dredged material on benthic organisms can be evaluated in Tier II (Figure 3-3). The approved procedure calculates the TBP for a test organism by factoring the concentration of the nonpolar organic chemical(s), the total organic carbon in the sediment, and the percent lipid concentration in the organism. This calculation predicts the magnitude of bioaccumulation likely to be associated with nonpolar organic contaminants in the dredged material. Additional guidance for identifying potential bioaccumulating contaminants is provided by EPA (1994a).

5.1 Water Column Impact

Program experience (primarily in marine, near coastal and estuarine waters) has shown that in most cases the existing data are sufficient to make water column determinations. However, Tier I evaluation may show that the existing information is insufficient to make a determination. If a WQS determination cannot be made in Tier I, Tier II evaluation is necessary to determine whether the discharge complies with 230.10(b)(1) (Figure 3-2). The discharge of dredged material cannot cause the WQS to be exceeded outside the mixing zone unless the State provides a variance to the standard.

There are two approaches for the Tier II water column evaluation for WQS compliance. One approach is to use the numerical models provided in Appendix C as a screen, assuming that all of the contaminants in the dredged material are released into the water column during the disposal process. The other approach applies the same model with results from chemical analysis of the elutriate test.

5.1.1 Screen Relative To WQS

The assumption that all of the contaminants in the dredged material are completely released into the water column during the discharge operation is conservative because, in virtually all cases, most of the contaminants remain within the dredged material. If the numerical model (Appendix C) predicts that the concentrations of all contaminants of concern after consideration of mixing are less than the available, applicable WQS, the dredged material complies with WQS. If the screen/model, as applied indicates that the WQS is exceeded, the elutriate analysis approach (Section 5.1.2) should be employed.

5.1.2 Elutriate Analysis Relative To WQS

For an elutriate analysis, the numerical mixing model (Appendix C) is run with chemical data obtained from an elutriate test conducted on the dredged material. The standard elutriate analysis is described in Section 10.1.2.1 and the analytical procedures for measuring constituents in the water are provided in Section 9.4.2. The model is, in effect, using data that more accurately represent the contaminant concentrations that will be present in the water column after consideration of mixing. If the numerical model (Appendix C) predicts that the concentration of all contaminants of concern at the edge of the mixing zone is less than the available, applicable WQS, the dredged material complies with WQS. Otherwise, it does not.

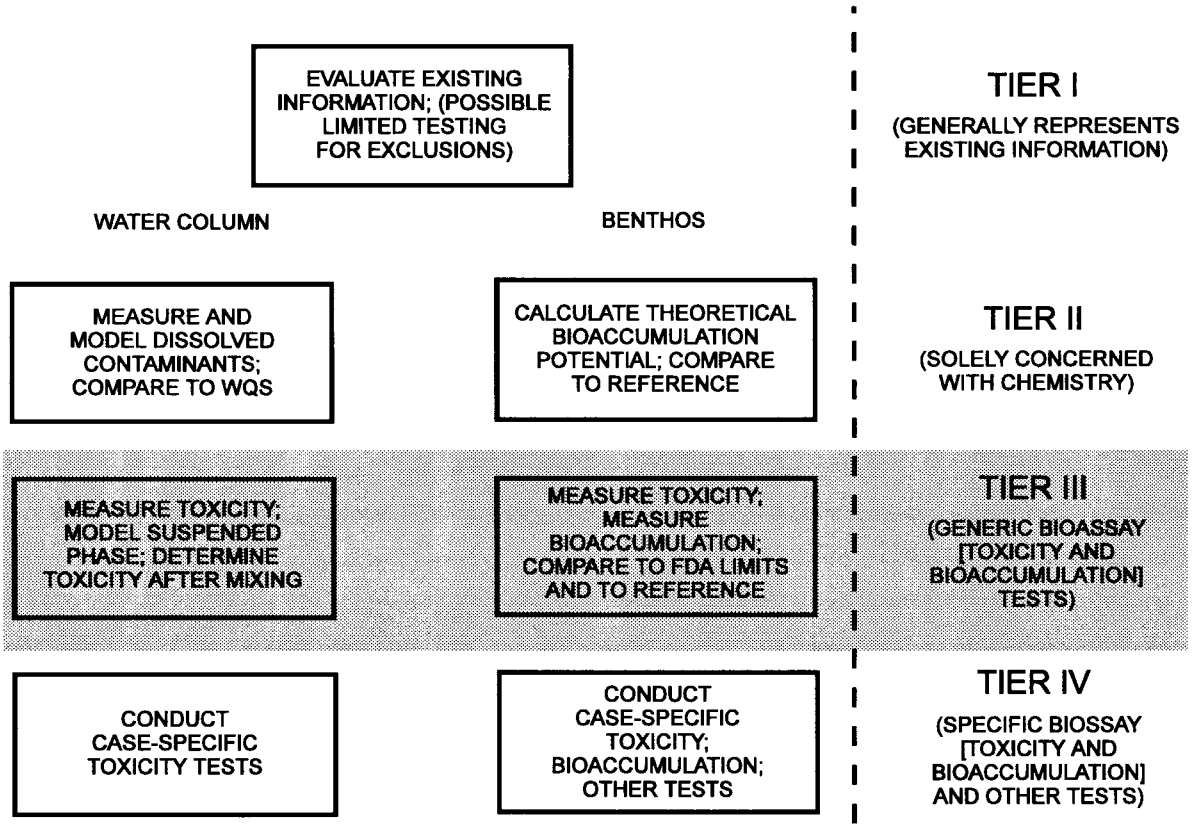
5.2 Benthic Impact

The currently available Tier II procedure for evaluating potential benthic impact consists of evaluating the TBP, calculated according to the guidance in Section 10.2. A comparison is made between the TBP calculated for the nonpolar organic contaminants of concern in dredged material and for the same constituents in the reference sediment. At present, this calculation can be performed for nonpolar organic compounds, but not for polar organic compounds, organometals, or metals. If such constituents are contaminants of concern in a dredged material requiring bioaccumulation evaluation, further evaluation has to take place in Tier III.

Even if the dredged material contains other contaminants of concern than nonpolar organic contaminants, it is still useful to calculate the TBP. The TBP provides an indication of the magnitude of bioaccumulation of nonpolar organics that may be encountered in actual testing (Tiers III and/or IV). Additionally, the calculation may eliminate the need for further evaluation of nonpolar organics and thereby reduce efforts in higher tiers.

5.3 Tier II Conclusions

One of two possible conclusions is reached regarding the potential water column impact of the proposed dredged material:



- The available WQS requirements are met. Further information on water column toxicity must be evaluated in Tier III when there are contaminants of concern for which applicable WQS are not available or where interactive effects are of concern.

- Concentrations of one or more of the dissolved contaminants of concern, after allowance for mixing, exceed available WQS beyond the boundaries of the mixing zone. In this case, the proposed discharge of dredged material does not comply with WQS.

For nonpolar organics, one of the following conclusions is reached based on comparison between the TBP for the dredged material and for the same contaminants in the reference sediment:

- The TBP for the nonpolar organic contaminants of concern in the dredged material does not exceed the TBP for the reference sediment and, therefore, the dredged material is predicted not to result in benthic bioaccumulation of the measured non-polar organic compounds. However, further evaluation of biological effects in Tier III is necessary to furnish information to make determinations under the Guidelines.

- The TBP for the nonpolar organic contaminants of concern in the dredged material exceeds the TBP for the reference sediment. In this case, the information is not sufficient to predict whether the dredged material will result in benthic bioaccumulation of the measured non-polar organic compounds, and further evaluation of bioaccumulation in Tier III is necessary to furnish information to make determinations under the Guidelines.

6.0 TIER III EVALUATION

Tier III testing assesses the impact of contaminants in the dredged material on appropriately sensitive and benchmark organisms to determine if there is the potential for an unacceptable (toxicity or bioaccumulation) impact at the disposal site. Lists of candidate test species (Sections 11 and 12: Tables 11-1 through 12-1) include consideration of: (1) appropriate sensitivity such that testing should not occur with insensitive organisms; (2) allowing appropriate Regional flexibility based on the list provided in this manual or the approved regional implementation manual; (3) providing some benchmark species for comparing (where appropriate) the sensitivity of regional species not widely used for such testing.

The Tier III assessment methods are bioassays (toxicity and bioaccumulation tests) (Figures 3-1 through 3-3). Generic guidance provided in this manual may have to be modified for specific species. Where possible and appropriate, organisms representative of the water column and benthic biota and conditions at the disposal site or the appropriate reference area should be used. Also, exposure routes must be appropriate (e.g., benthic test species must be truly benthic, that is, living on or in the sediment).

Presently, Tier III toxicity tests primarily use lethality as the endpoint. Chronic/sublethal tests for sediments are under development; none are considered to be currently suitable for wide-spread national use and hence are not included in this manual although regional use is allowed (cf. Section 11.2.3). New, appropriate benthic and water column tests, including sediment chronic/sublethal tests, will be included in future revisions of this manual as appropriate.

The recommended procedures for water-column toxicity tests (Figure 3-2) use appropriate sensitive water column organisms (Section 11.1.1, Table 11-1). The assay for benthic impact (Figure 3-3) uses deposited sediment and appropriately sensitive benthic organisms (Section 11.2.1, Table 11-2).

Bioaccumulation also has to be considered to fully evaluate potential benthic impact (Figure 3-3). The results of bioaccumulation tests are used to predict the potential for uptake of dredged-material contaminants by organisms (Kay, 1984).

Tier III information is usually sufficient for making factual determinations. Only in unusual cases is further information on toxicity or bioaccumulation (or both) necessary to make determinations under the Guidelines.

6.1 Water Column Toxicity Tests

Tier III (Figure 3-2) considers the effects on water column organisms, after allowance for mixing, of dissolved contaminants plus those associated with suspended particulates. The toxicity and mixing data results are generated as described in Section 11.1.

After considering the tests and considering mixing, one of the following conclusions is reached:

- If the 100% dredged material elutriate toxicity is not statistically higher than the dilution water (see Section 8.0, Table 8-1), the dredged material is not predicted to be acutely toxic to water column organisms.

- The concentration of dissolved plus suspended contaminants, after allowance for mixing, does not exceed 0.01 of the toxic (LC_{50} or EC_{50}) concentration beyond the boundaries of the mixing zone. Therefore the dredged material is predicted not to be acutely toxic to water column organisms. However, benthic impact has to be considered. If the information warrants, it is acceptable to determine water column effects at Tier III and benthic effects at another tier.

- The concentration of dissolved plus suspended contaminants, after allowance for mixing, exceeds 0.01 of the toxic (LC_{50} or EC_{50}) concentration beyond the boundaries of the mixing zone. Therefore, the dredged material is predicted to be acutely toxic to water column organisms.

6.2 Benthic Toxicity Tests

Evaluation of benthic (i.e., sediment) toxicity tests in Tier III (Figure 3-3) is based on data generated according to the guidance in Section 11.2. Dredged material is predicted to be acutely toxic to benthic organisms when mean test organism mortality:

- is statistically greater than in the reference sediment, and

- exceeds mortality (or other appropriate end point) in the reference sediment by at least 10% (the 10% value should be used unless a different value has been developed for specific test species and end-points for regulatory use, and is technically defensible; e.g.,

a 20% value for lethality can be used for the amphipods *Ampelisca abdita, Rhepoxynius abronius* and *Eohaustorius estuarius* (Swartz et al., 1985; Mearns et al., 1986; SAIC, 1992a,b)).

However, even if there is a certain level of toxicity (e.g., marginal mortalities for a single non-benchmark species), the preponderance of evidence could suggest that the sediment is not acutely toxic to benthic organisms. Acute toxicity testing of contaminants in the dredged material in Tier III will result in one of the following possible conclusions:

- Mortality (or other appropriate endpoint) in the dredged material is not statistically greater than in the reference sediment, or does not exceed mortality (or other appropriate endpoint) in the reference sediment by at least 10%. Therefore, the dredged material is predicted not to be acutely toxic to benthic organisms. However, bioaccumulation of contaminants also has to be considered. If the information warrants, it is acceptable to determine benthic toxicity at Tier III and bioaccumulation at another tier.

- Mortality (or other appropriate endpoint) in the dredged material is statistically greater than in the reference sediment and exceeds mortality (or other appropriate endpoint) in the reference sediment by at least 10%. In this case, the dredged material is predicted to be acutely toxic to benthic organisms.

6.3 Benthic Bioaccumulation

Body burdens of chemicals are of concern for both ecological and human health reasons. The Tier III benthic bioaccumulation tests (Section 12.1) are conducted for a subset of the contaminant of concern list based on the contaminant bioaccumulation properties discussed in Sections 4.2 and 10.2. These tests provide for the determination of bioavailability through 28-day exposure tests. For purposes of comparison with an action or tolerance level such as from Food and Drug Administration (FDA) as described below (or when conducting a Tier IV risk assessment), the duration of a bioaccumulation test should be sufficient for organisms to reach steady-state tissue residues for all compounds. However, the time to reach or approach steady-state varies among different compounds and, to a lesser extent, among species. Test designs that assure that steady-state has been attained require a large number of samples and substantial expense. As a cost-effective compromise, it is recommended that a 28 day exposure be used for the "standard" bedded sediment bioaccumulation test for neutral organics and metals.

Where it is desirable to know the steady-state concentration of neutral organic compounds as, for example, comparison to an FDA action level, fish advisory, or similar numerical values, the following procedure is recommended. The log Kow of the neutral organic compound of concern should be determined from Section 9.5.1 (Table 9-5). This should be compared with the log Kow in Figure 6-1 and will indicate the proportion of steady-state concentration (Css) expected in 28 days. This will allow estimation of the steady-state value from the 28-day laboratory exposure data through the use of a steady-state correction factor. The correction factor is the reciprocal of the decimal fraction indicating the proportion of Css expected in 28 days.

Bioaccumulation of most compounds, if it occurs, will be detectable after the 28-day exposure period, even though steady state may not have been reached. Thus, Tier III bioaccumulation tests provide useful information about the potential for bioaccumulation (i.e., bioavailability), even when steady-state tissue residues are not determined, e.g. when comparing to a reference sediment.

Concentrations of contaminants of concern in tissues of benthic organisms following dredged material exposure are compared to applicable Food and Drug Administration (FDA) Action or Tolerance Levels for Poisonous or Deleterious Substances in Fish and Shellfish for Human Food, when such levels (i.e., limits) have been set for the contaminants. The FDA levels (Table 6-1) are based on human-health as well as economic considerations (21 CFR 109 and 509), but do not indicate the potential for environmental impact on the contaminated organisms or the potential for biomagnification. Because contamination of food in excess of FDA levels is considered a threat to human health, EPA and USACE consider concentrations in excess of such levels in any test species to be predictive of benthic bioaccumulation of contaminants. This guidance applies even though the test species may not be a typical human food item partly because certain contaminants can be transferred through aquatic food webs, but mainly because uptake to FDA levels in relatively short term tests with one species may indicate the potential for accumulation in other species.

Based on tissue comparisons with FDA levels, one of the following conclusions is reached:

- Tissue concentrations of one or more contaminants are not statistically less than the FDA levels. Therefore, the dredged material is predicted to result in benthic bioaccumulation of contaminants.

- Tissue concentrations of all contaminants either are statistically less than FDA levels or there are no FDA levels for the contaminants. In this case, the information is insufficient to reach a conclusion with respect to benthic bioaccumulation of contaminants. The

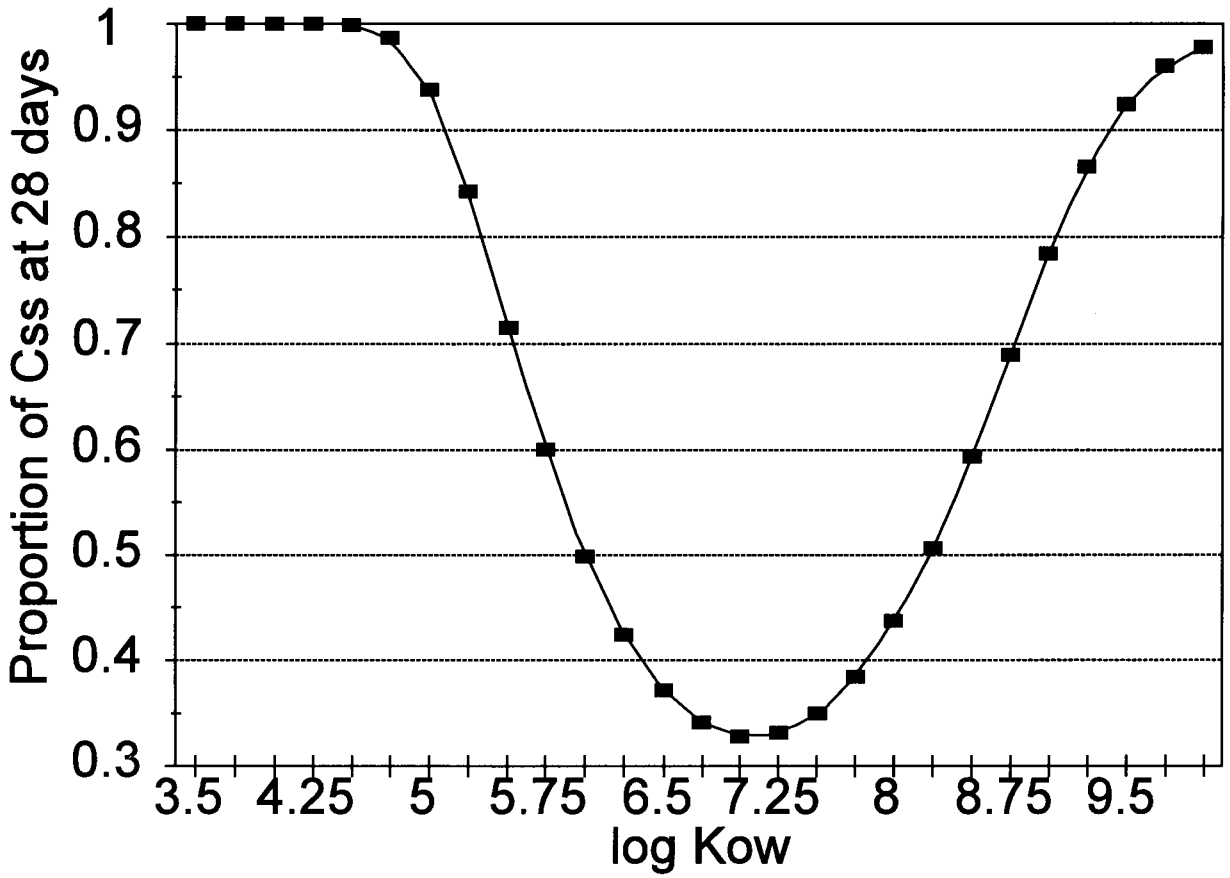

Figure 6-1. Expected proportion of steady-state concentration (Css) of neutral organic compounds reached in 28-day laboratory exposures. The proportion is a function of the log Kow of the compound of interest. Consult Section 9.5.1 (Table 9-5) for appropriate log Kow values. Figure adapted from McFarland (1994).

Table 6-1. Food and Drug Administration (FDA) Action Levels for Poisonous and Deleterious Substances in Fish and Shellfish for Human Food.[a]

Substance	Action Level[b]
Metals	
Methyl Mercury	1.0 ppm
Pesticides	
Chlordane	0.3 ppm
Chlordecone (Kepone)	0.3 ppm
DDT + DDE	5.0 ppm
Dieldrin + Aldrin	0.3 ppm
Heptachlor + Heptachlor Epoxide	0.3 ppm
Mirex	0.1 ppm
Industrial Chemicals	
PCBs[c]	(2.0 ppm)

[a] Action levels are established, revised, and revoked through notices published in the Federal Register. It is the responsibility of the users of the list to keep up to date on any amendments to this list. For further information on current action levels, users may contact the Food and Drug Administration, Center for Food Safety and Applied Nutrition, Industry Programs Branch [HFF-326, 200 C Street, S.W., Washington, DC 10204; (202) 205-5251].

[b] Action levels are reported in wet weight.

[c] There is no FDA action level for PCBs as a tolerance level has now been established (21 CFR part 109.30), which is equal to the previous action level.

dredged material needs to be further evaluated in Tier III as described below for bioaccumulation potential to furnish information to make determinations under the Guidelines.

Tissue contaminant concentrations following exposure to dredged material which are statistically less than FDA levels, or for which there are no such levels, are compared to tissue contaminant concentrations for organisms similarly exposed to reference sediment. One of the following conclusions is reached based on this comparison:

- Tissue concentrations of contaminants of concern in organisms exposed to dredged material do not statistically exceed those of organisms exposed to the reference sediment; therefore, the dredged material is predicted not to result in benthic bioaccumulation of contaminants. However, benthic toxicity effects also have to be considered.

- Tissue concentrations of contaminants of concern in organisms exposed to dredged material statistically exceed those of organisms exposed to the reference material. In this case, the final conclusion regarding benthic bioaccumulation of contaminants would be based upon technical evaluations that emphasize the various factors deemed appropriate in a particular region (see last paragraph in this section). Additional testing (Tier IV) may be required.

One other possibility exists: tissue concentrations are above FDA limits but are not statistically different from the reference (or disposal) site. This situation represents an exceptional case which can only be dealt with at the regional level.

The above comparisons to FDA values address human health concerns, and follow from EPA/USACE (1991). Other approaches which should be considered in addition to the use of FDA values include comparisons to state fish advisories, cancer and non-cancer risk models, existing ambient fish concentration data. State fish advisories exist for the following chemicals for which EPA risk-based screening values are being developed: (carcinogens) chlordane, DDT, dieldrin, hexachlorobenzene, lindane, toxaphene, PAH, PCBs, 2,3,7,8-TCDD; (noncarcinogens) endosulfan, mirex, cadmium, mercury, selenium, endrin. Methods to calculate carcinogenic and non-carcinogenic health risks are summarized in EPA (1989a). "Computerized Risk and Bioaccumulation System", an expert system for PC computers, is available to predict tissue residues in sediment-dwelling shellfish and the associated excess cancer risk (Lee et al., 1990). Note that this program does not calculate risks associated with mobile invertebrates or fishes, and that it should be used only to supplement data derived from other methods.

Reference comparisons are made for the protection of aquatic life as well as human health because bioaccumulation is both undesirable and an indicator of bioavailability (Figure 3-3). It is recognized that residue effects information does not exist to fully interpret bioaccumulation data; the approach followed in this manual is the best presently available.

When the bioaccumulation of contaminants in dredged-material tests statistically exceeds that in reference-material tests, five factors should be assessed. Where available, regional guidance should be consulted regarding the relative importance of these factors:

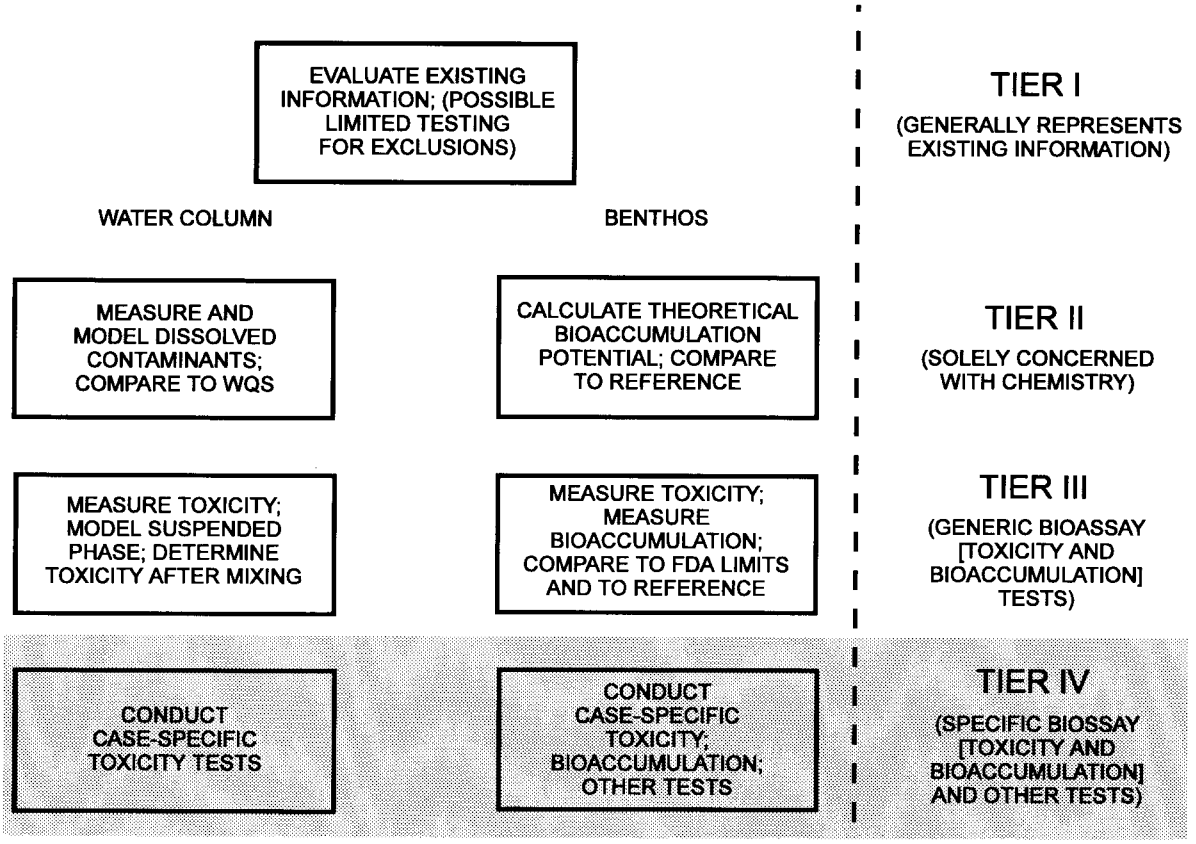
- What is the toxicological importance of the contaminants (e.g., Do they biomagnify? Do they have effects at low concentrations?) whose bioaccumulation from the dredged material statistically exceeds that from the reference material?

- By what magnitude does bioaccumulation from the dredged material exceed bioaccumulation from the reference material?

- What is the propensity for the contaminants with statistically significant bioaccumulation to biomagnify within aquatic food webs (Kay, 1984)? Contaminants which biomagnify appear to be few in number but widespread, and include DDT, PCB, methylmercury and, possibly, dioxins and furans.

- What is the magnitude by which contaminants whose bioaccumulation from the dredged material exceeds that from the reference material also exceeds the concentrations found in comparable species living in the vicinity of the proposed disposal site?

- For how many contaminants is bioaccumulation from the dredged material statistically greater than bioaccumulation from the reference material?



6.4 Tier III Conclusions

The above five factors and perhaps other factors are complexly interrelated; i.e., the importance of each factor depends on its interaction with all other factors. These factors have to be considered in case-specific determinations (if needed) for dredged material assessed for bioaccumulation in the final step of Tier III. After considering these factors, one of the following Tier III conclusions is reached:

- Discharge of the dredged material is predicted not to result in above-reference toxicity or benthic bioaccumulation of contaminants.

- Discharge of the dredged material is predicted to result in above-reference toxicity or bioaccumulation of contaminants.

- Further information is needed to make factual determinations, specifically in Tier IV.

7.0 TIER IV EVALUATION

Tier IV involves case-specific, state-of-the-art testing for toxicity and/or bioaccumulation and is to be used on a case-by-case basis only when lower tiered testing is judged to be insufficient to make complete factual determinations. Insufficient information for a determination may include: inability to reach a clear conclusion based on existing data; statistical differences are inconclusive; evidence is conflicting. Experience to date suggests that Tier IV should only be used in a very few cases. When methods are suitable for wide-spread national use, sediment chronic/sublethal testing will be part of Tier III. Until such time as sediment chronic/sublethal tests are approved for national use in Tier III, they should only be used in Tier IV. However, regional testing manuals may apply appropriate sediment chronic/sublethal tests in Tier III in advance of their inclusion in this national manual provided this is done with a benchmark species (Section 11.2.1) or *in addition to* the testing presently required in Tier III.

Tier IV tests may be conducted for water column evaluations (Figure 3-2) or benthic evaluations (Figure 3-3). In both cases, tests should be carefully selected to address the specific issues relevant to the case in question. Tier IV can further consider human and ecological health concerns, including risk assessment. Case-specific evaluative criteria for Tier IV tests must be:

- agreed upon by EPA and USACE and, where appropriate, the State
- adequate to make factual determinations.

7.1 Toxicity Tests

Tier IV toxicity tests (Figure 3-2) should measure end-points of clear ecological importance, for example survival, growth and reproduction. Differences from Tier III tests may include:

- longer duration of exposure
- different species
- different end-points
- exposure in the disposal site environs.

Toxicity determinations in this tier can involve laboratory or field testing or field assessments of resident benthic communities. Field assessments can be difficult to interpret but can yield valuable information on responses of resident organisms to in-place contaminants at the dredging site as compared to a disposal site or site environs as appropriate.

Toxicity identification evaluation procedures (e.g., Ankley et al., 1992a) can also be used in this tier. Such procedures can be applied to sediments when ammonia or hydrogen sulfide could be responsible for toxicity.

7.2 Benthic Bioaccumulation

Tier IV bioaccumulation tests (Figure 3-3) differ from Tier III tests in that steady-state tissue concentrations of contaminants of concern are always determined. Such determinations can be made by: longer laboratory exposures than used in Tier III, collecting tissue samples from the field (Section 12.2.2), or *in situ* exposures using transplanted organisms.

Tissue concentrations determined in Tier IV are subject to the same comparisons as in Tier III, specifically to FDA action limits, and to comparisons with organisms exposed to reference sediment. Conclusions possible from such comparisons and evaluative factors which should be assessed are detailed in Section 6.3 and can include risk assessments and no effects levels for aquatic life, rather than solely the first two comparisons.

Prediction of the movement of contaminants from sediment into and through pelagic food webs is technically challenging and should only be dealt with if a Tier IV evaluation is necessary. One approach is bioenergetic-based toxicokinetic modeling. These models have been successfully applied to marine (Connolly and Tonelli, 1985) and freshwater (Norstrom et al., 1976) fishes, theoretical food chains (Thomann, 1989), and more recently to sediment organisms (Boese et al., 1990). These models are very data intensive to apply on a chemical and site-specific basis. It is possible to use values determined through QSAR (EPA, 1994a), though the default values may substantially overestimate tissue residues in metabolizable compounds, such as PAH. Another general approach is to bracket likely concentrations of specific contaminants at different trophic levels based on an empirical model derived from a variety of marine food webs (Young, 1988).

PART III - SAMPLING AND ANALYSIS

8.0 SAMPLING

When testing is necessary, samples of dredged material, reference sediment, control sediment, organisms, and water will be needed for physical evaluations, chemical analysis, and for bioassay tests. This section provides general guidance for the development of a sampling plan including collection, handling and storage.

Sampling is the foundation upon which all testing rests but there are so many case-specific factors that influence sampling needs that detailed guidance of National scope is impractical. Some regions of the country have developed specific technical requirements and agency review/approvals of sampling and analysis plans. Regional guidance from local EPA and USACE offices should be sought for developing project-specific sampling plans as for information gathered at Tier I. The type of samples that may be required to complete the evaluations of Tiers II, III, and IV are outlined in Table 8-1. This manual provides general guidance on items of major importance to consider when designing a sampling plan. Additional guidance is provided by EPA (1995).

8.1 Preparation For Sampling

A well-designed sampling plan is essential when evaluating the potential impact of dredged material discharge upon the aquatic environment. Before any sampling is initiated, the sampling plan has to be tailored to meet clearly defined objectives for individual dredging operations. Factors such as the availability and content of historical data, the degree of sediment heterogeneity, the dredging depth, the number and geographical distribution of sample-collection sites, the procedures for collection, preservation, storage, and tracking of samples, and the necessity for adequate quality assurance and quality control (Appendix G; EPA, 1995) must be carefully considered. The magnitude of the dredging operation and its time and budgetary constraints should also be considered.

It is recommended that a written plan for sediment sampling and analyses be prepared and provided to the appropriate Federal and State agencies for coordination prior to sampling, where practicable. The Tier I evaluation would be a logical attachment to the sampling and analysis plan for agency review and comment. This coordination can reduce the chance of having to repeat costly procedures and can assist in keeping projects on schedule. An adequate amount of sediment and water should be collected to conduct planned evaluations and allow for any contingencies. Maximum allowable and recommended sample and organism holding times as well as the exigencies of resampling should be given careful consideration.

Table 8-1. Type of Samples Which May Be Required Following Tier I to Conduct Dredged-Material Evaluation Tests. Actual sampling requirements are project-specific and are determined during the development of the project plan. Sampling from the disposal site may also be conducted as necessary and appropriate, to verify the applicability of exclusion 230.60 (C) (see Sections 4.0 and 9.1.)

[a]May or may not have to be field-collected.

[b]Dilution water for water column toxicity tests. Artificial or clean seawater or clean freshwater may also be used.

[c]Disposal site water is required for WQS comparison. Elutriate samples are prepared with dredging site water.

The importance of sampling is underscored by the fact that any evaluation is only as complete and reliable as the sampling (and sample handling and storage) upon which it is based. Thus, inadequacies or biases in sampling will limit the accuracy and/or the usefulness of the study results.

The primary objective of sediment and water collection is to obtain samples to adequately and accurately characterize the dredging and reference area. Sample size should be large enough to attain the appropriate detection limits but small enough to be conveniently handled and transported within the requirements for all planned analyses. The quality of the information obtained through the testing process is impacted by the following four factors:

- collecting representative samples
- collecting an appropriate number of samples
- using appropriate sampling techniques
- protecting or preserving the samples until they are tested.

Ideally, the importance of each of these three factors will be fully understood and appropriately implemented. In practice, however, this is not always the case. There may be occasions when study needs, time, costs or other resource constraints will limit the amount of information that should or can be gathered. When this is the case, the relative importance of each of these factors has to be carefully considered in light of the specific study purposes.

An important component of any field sampling program is a preproject meeting with all concerned personnel. Personnel involved may include management, field personnel, laboratory personnel, data management/analysis personnel, and representatives of regulatory agencies, the permit applicant, and the dredging company. To assure sampling quality, at least one individual familiar with the study area should be included in the preproject meeting. The purposes of the meeting include:

- defining the objectives of the sampling program
- ensuring communication among participating groups
- ensuring agreement on methods, QA/QC details and contingency plans.

The more explicitly the objectives of a testing program can be stated, the easier it will be to design an appropriate sampling plan. A complete sampling plan will result in a level of detail such that all sampling procedures and locations are clearly defined, sample volumes are clearly established, all logistical concerns are fully addressed, and target analytes are identified to class of compound.

8.2 Components Of A Sampling Plan

The following steps will help to ensure that all essential sampling plan information is provided:

- Review the plan for the proposed dredging operation, including the dimensions of the dredging area, the dredging depth(s), side-slopes, the volume of sediment for disposal, and the type of dredge equipment (e.g., clamshell, hydraulic) for determining composite sampling or delineating representative project segments.
- Evaluate the prior history and the existing database for the area, in particular, information gathered in Tier I. Identify relevant data and the need for additional data. Identify areas of potential environmental concern within the confines of the dredging operation.
- If appropriate, subdivide the dredging area into project segments on the basis of an assessment of level of environmental concern within the dredging area. This may be an iterative process that starts before sampling, using available information, and that is refined after sampling, based on new data.
- Determine the number of samples to be collected and select sampling locations. Choose methods and equipment for positioning vessels at established stations.
- Determine what sampling methods will be used.
- Define procedures for sample handling, preservation, storage, and (if applicable) field or shipboard analysis.
- Identify logistical considerations and safety precautions.

The subsections that follow discuss each of these steps and provide general guidance for their conduct. An essential step, preparation of a quality assurance/quality control (QA/QC) project plan, is discussed in detail in Appendix G and EPA (1995) and must be integral to the project. The QA/QC plan is essential to ensure that there will be sufficient and appropriate data of known and documented quality to make decisions with confidence and to defend those decisions. Properly prepared, a QA/QC plan expedites project coordination.

8.2.1 Review of Dredging Plan

A review of the plan for the dredging operation provides a basis for determining the sampling strategy. The volume of material to be dredged and the method of dredging are two important factors which will help to determine the number of samples required. The number of samples required is generally a judgement which considers the cost, resolution, and the risk of an incorrect decision regarding the volume of material to be dredged. Knowledge of the depth and physical characteristics of the material to be

dredged will help to determine the kind of sampling equipment that is required. The boundaries of the dredging area have to be known to ensure that the number and location of samples are appropriate. Sampling should generally be to the project depth (including overdredging) unless the sediments are known to be vertically homogeneous.

8.2.2 Historical Data

All information relevant to the dredging site should be reviewed. Using pertinent available information to determine project segments and station locations within the dredging area is both cost and technically effective. If a review of historical data identifies possible sources of contamination, skewing the sampling effort toward these areas may be justified for thorough characterization of these areas, but can lead to an incomplete assessment of contamination in the whole area. In areas of unequally distributed contamination, the total sampling effort should be increased to ensure representative, but not necessarily equal, sampling of the entire site. Sediment sampling techniques are detailed in Mudroch and MacKnight (1991). The information gathered for the Tier I evaluation (discussed in Section 4.1) should be reviewed for assistance in designing the sampling plan, in particular the following:

- **Geotechnical and hydrodynamic data**
  The grain size, specific gravity, water or solids content, total organic carbon (TOC) and identification of sediment horizons are helpful in making operational decisions. Areas of high currents and high wave energy tend to have larger grain-sized sediments than do quieter areas. Many contaminants have a greater affinity for clay and silt than for sand. Horizontal and vertical gradients may exist within the sediment. Local groundwater quality and movement should be determined if groundwater is a potential source of contamination.

- **Quality and age of available data**
  The value of the available data should be critically weighed. Existing high-quality data might lower costs by reducing the number of analytes measured or tests required for the proposed dredging operation. Existing data that do not meet all quality assurance/quality control (QA/QC) standards may still be useful if appropriate calibration and documentation are available; they are less useful if older methods with higher detection limits were used. Information from such studies might be helpful in identifying areas of contamination, but not in accurately assessing the degree of contamination.

- **Known distribution of contaminants**
  All evidence regarding contaminants within or near the dredging area, including spill data, may be an important consideration in identifying locations for sampling and/or determining sampling intensity.

- **Dredging history**
  Knowledge of prior dredging may dramatically affect sampling plans. If the area is frequently dredged (every 1-2 years) or if the sediments are subject to frequent mixing by wave action, currents, or ship traffic, the sediments are likely to be relatively homogeneous. Assuming that there is no major contaminant input, the sampling effort may be minimal. However, if there is information regarding possible contamination or heterogeneity is possible, a more extensive sampling effort may be indicated. New excavations of material unaffected by anthropogenic input may require less intensive sampling than maintenance dredging.

8.2.3 Subdivision of Dredging Area

Sediment characteristics are likely to vary substantially within the limits of the area to be dredged as a result of geographical and hydrological features. Areas of low hydrodynamic energy will be characterized by fine sediments that have a greater tendency to accumulate contaminants than do coarser-grained sediments. (However note that contaminants, if present in coarse-grained sediments, may be more bioavailable than if present in fine-grained sediments). Sediments in and downstream of heavily urbanized or industrialized areas are more likely to accumulate contaminants than sediments farther removed from direct contaminant input.

Many dredging operations can be subdivided into project segments (horizontal and/or vertical) which can be treated as separate management units. A project segment is an area expected to have relatively consistent characteristics that differ substantially from the characteristics of adjacent segments. Project segments may be sampled with various intensities and, if warranted by the study objectives and test results, the dredged material from various project segments can be managed differently during dredging and disposal to limit environmental impact. When the sampling plan is developed, project segments can be designated, based on factors including but not limited to: historical data, sediment characteristics, geographical configuration, anticipated method of dredging, depth of cut, sampling- or dredging-equipment limitations, results of pilot studies, and known or suspected contaminant concentrations. Surface sediments might be considered separately from subsurface sediments at the same location if vertical stratification of contamination is expected or encountered. Large dredging operations located

within industrialized areas might require subdivision into several project segments horizontally and into one or more segments vertically. A dredging operation characterized by relatively uniform distribution of sediment type in a nonindustrialized location might be considered as a single project segment. Vertical subdivisions usually are not appropriate in areas of rapid shoaling or in areas of high sediment mixing by ship scour, which are likely to be relatively homogenous vertically. Vertical subdivisions smaller than about 1 m are usually impractical because dredge operators generally cannot reliably control excavation with any finer precision; vertical subdivisions should reflect the actual removal precision to be employed during the dredging operation. If analytical data and test results for two or more project segments prove to be similar, these segments may be treated as one larger segment when considering disposal options. If the analytical and test results demonstrate important differences between project segments, alternative disposal options may be necessary for portions of the total sediment volume.

Any established sampling program should be sufficiently flexible to allow changes based on field observations; however, any deviations from the sampling plan must be documented, along with the rationale for such deviations. Certain characteristics of the sediments, such as color or texture, can be an indication of patchiness. The greater the patchiness, the larger the number of samples that will be required to adequately characterize the area. The project manager can refine a sampling program based on historical data and/or a preliminary sampling survey of the dredging area.

8.2.4 Selection of Sampling Locations and Number of Samples

Generally a single sampling strategy will be adequate for most circumstances. However, in some cases, two sampling strategies may be required. For instance, when sampling involves both uncontaminated and highly contaminated sediments with interfaces between the two, a single sampling strategy may not be sufficient to adequately characterize these sediments, which will probably be treated differently.

The method of dredging, the volume of sediment to be removed, the areal extent of the dredging project, and the horizontal and vertical heterogeneity of the sediment are key to determining station locations and the number of samples to be collected for the total dredging operation and for each project segment. When appropriate to testing objectives, samples may be composited prior to analysis (with attention to the discussion later in this section). The appropriate number of samples and the proper use of compositing should be determined for each operation on a case-by-case basis. Note that the following detailed discussion is not appropriate to all dredging operations. Sampling a number of small, isolated shoals is very different than sampling a large, contiguous open area.

Factors to Consider:

The following factors, many of which follow from information gathered in Tier I, should be among those considered in sampling station and pattern selection:

- objectives of the testing program
- bathymetry
- area of the dredging project
- accessibility
- flows (currents, tides)
- mixing (hydrology)
- sediment heterogeneity
- contaminant source locations
- land use activities
- available resources
- other physical characteristics.

Station Locations:

Station locations within the dredging area should include locations downstream from major point sources and in quiescent areas, such as turning basins, side channels, and inside channel bends, where fine-grained sediments are most likely to settle. Characteristics which help to define the representativeness of station(s) within a segment include:

- The distribution of sediments to be dredged is clearly defined.
- The project segment being sampled is clearly defined.
- The sampling locations are distributed appropriately within each project segment.
- Multiple samples should be collected if sample variability is suspected.
- When sediment variability is unknown, it may be necessary to conduct a preliminary survey of the dredging area to better define the final sampling program.

Sample Replication:

Within a station, samples may be collected for replicate testing. For this manual, laboratory replicates are generally recommended as opposed to field replicates, depending on site-specific issues. The former (subsamples of a composite sample of the replicates) involves pseudo-replication compared to separate samples for each replicate, but is more appropriate for dredged material evaluations where sediments will

be homogenized by the dredging and discharge process. The latter involves true replication but is more appropriate for field investigations of the extent and degree (or not) of homogeneity of sediment toxicity.

Depth Considerations:

Sediment composition can vary vertically as well as horizontally. Samples should be collected over the entire dredging depth (including over-dredging), unless the sediments are known to be vertically homogeneous or there are adequate data to demonstrate that contamination does not extend throughout the depth to be excavated. Separate analyses of defined sediment horizons may be useful to determine the vertical distribution of contamination if warranted by the study objectives. A major consideration of vertical compositing is the anticipated depth of dredging. For example, even though sediments in a 1 m shoal may vary in composition, the material would be mixed as a result of the dredging process.

Sampling Bias:

Ideally, the composition of an area and the composition of the samples obtained from that area will be the same. However, in practice, there often are differences due to bias in the sampling program, including disproportionate intensity of sampling in different parts of the dredging area and equipment limitations.

In some cases, to minimize bias, it may be useful to develop a sampling grid for each project segment. The horizontal dimensions of each project segment may be subdivided into grid cells of equal size, which are numbered sequentially. Cells are then selected for sampling either randomly or in an stratified random manner. It can be important to collect more than the minimum number of samples required, especially in areas suspected of having high or highly variable contamination. In some cases, although additional costs and logistic considerations will apply, extra samples may be archived (for long time periods in the case of physical characterization or chemical analyses and for short time periods in the case of biological tests), should reexamination of particular project segment(s) be warranted.

In other cases, a sampling grid may not be desirable. This is particularly the case where dredging sites are not continuous open areas, but are rather a series of separate humps, bumps, reaches and pockets with varying depths and surface areas. In these latter cases, sample distribution is commonly biased with intent.

Level of Effort:

In some cases, it may be advisable to consider varying the level of sampling effort. Project segments suspected or known to be contaminated may be targeted for an increased level of effort so that the

boundaries and characteristics of the contamination can be identified. A weighting approach can be applied whereby project segments are ranked in increasing order of concern, and level of concern can then be used as a factor when determining the number of samples within each project segment relative to other project segments.

Number of Samples:

In general, the number of samples that should be collected within each project segment is inversely proportional to the amount of known information, and is proportional to the level of confidence that is desired in the results and the suspected level of contamination. No specific guidance can be provided, but the following factors should be considered:

- the greater the number of samples collected, the better the areal and/or vertical definition
- single measurements are inadequate to describe variability
- the means of several measurements at each station within a project segment generally are less variable than individual measurements at each station.

Time and Funding Constraints:

In all cases, the ultimate objective is to obtain sufficient information to evaluate the environmental impact of a dredged material disposal operation. The realities of time and funding constraints have to be recognized, although such do not justify inadequate environmental evaluation. Possible responses to cost constraints have been discussed by Higgins (1988). If the original sampling design does not seem to fit time or funding constraints, several options are available, all of which increase the risk of an incorrect determination:

- Reduce the number of project segments into which the project is divided, but maintain the same total number of samples.
- Maintain (or even increase) the number of stations sampled, and composite multiple samples from within a project segment so that a lower number of analyses are performed per project segment.

Project Segments:

Regardless of the final decision on project segments and the number of sample stations and replicates per project segment, expected or known degree of contamination will be the dominant factor in initially describing the proposed project segments. If variation in potential dredged material impact within a project segment is likely, where possible it may be advisable either to use a stratified random-sampling approach or to redefine project-segment boundaries. Once sampling data are available, it is advisable to reconsider the boundaries of the project segments to be used in the actual dredging in order to maximize homogeneity within segments.

Sample Compositing:

The objective of obtaining an accurate representation and definition of the dredging area and method has to be satisfied when compositing samples. Compositing provides a way to control cost while still analyzing sediments from a large number of stations. Compositing results in a less detailed description of variability within the area sampled than would individual analysis at each station. However if, for example, five analyses can be performed to characterize a project segment, the increased coverage afforded by collecting 15 individual samples and combining sets of three into five composite samples for analysis may justify the increased time and cost of collecting the extra 10 samples. Compositing can also provide the large sample volumes required for some biological tests. Composite samples represent the "average" of the characteristics of the individual samples making up the composite and are generally appropriate for logistic and other reasons; however, composite samples which serve to "dilute" a highly toxic but localized sediment "hot spot" are not recommended. Further, composite samples are not recommended for stations with very different sediment grain size characteristics.

Sample Definition:

When a sediment sample is collected, a decision has to be made as to whether the entire sediment volume is to be considered as the sample or whether the sediment volume represents separate samples. For instance, based on observed stratification, the top 1 m of a core might be considered to be a separate sample from the remainder of the core. After the sediment to be considered as a sample is identified, it should be thoroughly homogenized. Samples may be split before compositing, with a portion of the original sediment archived for possible later analysis, and the remainder combined with parts of other samples. These are then thoroughly homogenized (using clean instruments until color and textural homogeneity are achieved), producing the composite sample.

8.2.5 Sample Collection Methods

Sample collection requires an adequately trained crew, an adequate vessel equipped with navigational and supporting equipment appropriate to the site and the study, and noncontaminating sampling apparatus capable of obtaining representative samples. Divers may also be used in some cases to collect some samples; in such cases divers must be certified and approved diver safety management plans must be in place. To assure sampling quality, at least one individual familiar with the study area should be present during the sampling activities. Sampling effort for a proposed dredging operation is primarily oriented toward collection of sediment samples for physical and chemical characterization and for biological tests. Collection of water samples is also required to evaluate potential water column impact. Collection of organisms near the disposal site might be necessary if there is a need to characterize indigenous populations or to assess concentrations of contaminants in tissues. Organisms for use in toxicity and bioaccumulation tests may also be field-collected.

In general, a hierarchy for sample collection should be established to prevent contamination from the previous sample, especially when using the same sampling apparatus to collect samples for different analyses. Where possible, the known, or expected, least contaminated stations should be sampled first. At a station where water and sediment are to be collected, water samples should be collected prior to sediment samples. The vessel should ideally be positioned downwind or downcurrent of the sampling device. When raising or lowering sampling devices, care should be taken to avoid visible surface slicks and the vessel's exhaust. The deck and sample handling area should be kept clean to help reduce the possibility of contamination.

8.2.5.1 Sediment Sample Collection

Mudroch and MacKnight (1991) provide useful reference information. Higgins and Lee (1987) provide a perspective on sediment collection and analysis as commonly practiced in USACE Districts. ASTM (1994a) and Burton (1991) provide guidelines for collecting sediments for toxicological testing. Guidance provided in these publications may be followed on all points that do not conflict with this manual.

Care should be taken to avoid contamination of sediment samples during collection and handling. A detailed procedure for handling sampling equipment and sample containers should be clearly stated in the sampling plan associated with a specific project. This may be accomplished by using standard operating procedures (SOPs). For example, samples designated for trace metal analysis should not come into contact with metal surfaces (except stainless steel, unless specifically prohibited for a project), and samples designated for organic analysis should not come into contact with plastic surfaces. Samples for

biological tests may be stored in clean polypropylene containers. Subsamples for particular groups of analytes may be removed from areas of the sample not in physical contact with the collecting instrument.

A coring device with appropriate liners is recommended whenever sampling to depth is required. The choice of corer design depends upon factors including the objectives of the sampling program, sediment volumes required for testing, sediment type, water depth, sediment depth, and currents or tides. A gravity corer may be limited to cores of 1-2 m in depth, depending upon sediment grain size, degree of sediment compactness, and velocity of the drop. For penetration greater than 2 m, a vibratory corer or a piston corer is generally preferable. These types of coring devices are generally limited to soft, unconsolidated sediments. A split-spoon core may be used for more compacted sediment. The length of core that can be collected is usually limited to 10 core diameters in sand substrate and 20 core diameters in clay substrate. Longer cores can be obtained, but substantial sample disturbance results from internal friction between the sample and the core liner.

Freefall cores can cause compaction of the vertical structure of sediment samples. Therefore, if the vertical stratification in a core sample is of interest, a piston or vibra corer should be used. Piston corers use both gravity and hydrostatic pressure. As the cutting edge penetrates the sediments, an internal piston remains at the level of the sediment/water interface, preventing sediment compression and overcoming internal friction. A vibra corer is a more complex piece of equipment but is capable of obtaining 3- to 7-m cores in a wide range of sediment types by vibrating a large diameter core barrel through the sediment column with little compaction. If the samples will not be sectioned prior to analysis, compaction is not a problem, and noncontaminating freefall corers are a suitable alternative.

Corers are the samplers of preference in most cases because of the variation in contamination with depth that can occur in sediment deposits. Substantial variation with depth is less likely in shallow channel areas without major direct contaminant inputs, that have frequent ship traffic, and from which sediments are dredged at short intervals. Generally, in these situations, accumulating sediments are resuspended and mixed semicontinuously by ship scour and turbulence, effectively preventing stratification. In such cases, surface grab samples can be representative of the mixed sediment column, and corers should be necessary only if excavation of infrequently disturbed sediments below the mixed layer is planned.

Grab samplers are also appropriate for collecting surficial samples of reference or control sediments. A grab can be Teflon-coated to prevent potential contamination of trace metal samples. The sampling device should at least be rinsed with clean water between samples and possibly also solvent-rinsed.

8.2.5.2 Water Sample Collection

If water samples are necessary, representative samples should be collected with either a noncontaminating pump or a discrete water sampler. When sampling with a pump, the potential for contamination can be minimized by using a peristaltic or a magnetically coupled impeller-design pump. The system should be flushed with the equivalent of 10 times the volume of the collection tubing. Also, any components within several meters of the sample intake should be noncontaminating (i.e., sheathed in polypropylene or epoxy-coated). Potential sample contamination must be avoided, including vessel emissions and other sampling apparatus.

A discrete water sampler should be of the close/open/close type so that only the target water sample comes into contact with internal sampler surfaces. Seals should be Teflon-coated whenever possible. Water sampling devices should be acid-rinsed (1:1 nitric acid) prior to use for collection of trace-metal samples, and solvent-rinsed prior to collection of samples for organic analyses.

8.2.5.3 Organism Collection

Benthic organism collection methods may be species specific and can include, but are not restricted to, bottom trawling, grabs or cores. If organisms are to be maintained alive, they should be transferred immediately to containers with clean, well-oxygenated water, and sediment as appropriate. Care must be taken to prevent organisms from coming into contact with potentially contaminated areas or fuels, oils, natural rubber, trace metals, or other contaminants.

8.2.6 Sample Handling, Preservation, and Storage

Detailed procedures for sample handling, preservation, and storage should be part of the standard operating procedures and protocols developed for each sampling operation. Samples are subject to chemical, biological, and physical changes as soon as they are collected. Sample handling, preservation, and storage techniques have to be designed to minimize any changes in composition of the sample by retarding chemical and/or biological activity and by avoiding contamination. Collection methods, volume requirements, container specifications, preservation techniques, storage conditions and holding times (from the time of sample collection) for sediment, water, and tissue samples are discussed below and summarized in Table 8-2.

8.2.6.1 Sample Handling

Sufficient sample volume must be collected to:

Table 8-2. Summary of Recommended Procedures for Sample Collection, Preservation, and Storage.[a]

Analyses	Collection Method[b]	Amount Required[c]	Container[d]	Preservation Technique	Storage Conditions	Holding times[e]
SEDIMENT						
Chemical/Physical Analyses						
Metals	Grab/corer	100 g	Precleaned polyethylene jar[f]	Dry ice[f] or freezer storage for extended storages; otherwise refrigerate	≤ 4°C	Hg - 28 days Others - 6 months[g]
Organic compounds (e.g., PCBs, pesticides, polycyclic aromatic hydrocarbons)	Grab/corer	250 g	Solvent-rinsed glass jar with Teflon lid[f]	Dry ice[f] or freezer storage for extended storages; otherwise refrigerate	≤ 4°C[f]/dark[g]	14 days[h]
Particle size	Grab/corer	100 g	Whirl-pac bag[f]	Refrigerate	< 4°C	Undetermined
Total Organic Carbon (TOC)	Grab/corer	50 g	Heat treated glass vial with Teflon-lined lid[f]	Dry ice[f] or freezer storage for extended storages; otherwise refrigerate	≤ 4°C[f]	14 days
Total solids/ specific gravity	Grab/corer	50 g	Whirl-pac bag	Refrigerate	< 4°C	Undetermined
Miscellaneous	Grab/corer	≥ 50g	Whirl-pac bag	Refrigerate	< 4°C	Undetermined

Table 8-2 *(continued)*

Analyses	Collection Method[b]	Amount Required[c]	Container[d]	Preservation Technique	Storage Conditions	Holding times[e]
SEDIMENT (continued)						
Sediment from which elutriate is prepared	Grab/corer	Depends on tests being performed	Glass with Teflon-lined lid	Completely fill and refrigerate	4°C/dark/airtight	14 days
Biological Tests						
Dredged material	Grab/corer	12-15 L per sample	Plastic bag or container[i]	Completely fill and refrigerate; sieve	4°C/dark/airtight	14 days[j]
Reference sediment	Grab/corer	45-50 L per test	Plastic bag or container[i]	Completely fill and refrigerate; sieve	4°C/dark/airtight	14 days[j]
Control Sediment	Grab/corer	21-25 L per test	Plastic bag or container[i]	Completely fill and refrigerate; sieve	4°C/dark/airtight	14 days[j]
WATER AND ELUTRIATE						
Chemical/Physical Analyses						
Particulate analysis	Discrete sampler or pump	500 - 2000 mL	Plastic or glass	Lugols solution and refrigerate	4°C	Undetermined
Metals	Discrete sampler or pump	1 L	Acid-rinsed polyethylene or glass jar[k]	pH <2 with HNO_3[k]; refrigerate	4°C 2°C[k]	Hg - 14 days Others - 6 months[l]
Total Kjeldahl nitrogen (TKN)	Discrete sampler or pump	100 - 200 mL	Plastic or glass[l]	H_2SO_4 to pH <2; refrigerate	4°C[l]	24 h[l]
Chemical oxygen demand (COD)	Discrete sampler or pump	200 mL	Plastic or glass[l]	H_2SO_4 to pH <2; refrigerate	4°C[l]	7 days[l]

Table 8-2 *(continued)*

Analyses	Collection Method[b]	Amount Required[c]	Container[d]	Preservation Technique	Storage Conditions	Holding times[e]
WATER AND ELUTRIATE (continued)						
Total organic carbon (TOC)	Discrete sampler or pump	100 mL	Plastic or glass[l]	H_2SO_4 to pH <2; refrigerate	4°C[l]	<48 h[l]
Total inorganic carbon (TIC)	Discrete sampler or pump	100 mL	Plastic or glass[l]	Airtight seal; refrigerate[h]	4°C[l]	6 months[l]
Phenolic compounds	Discrete sampler or pump	1 L	Glass[l]	0.1 - 1.0 g $CuSO_4$; H_2SO_4 to pH <2; refrigerate	4°C[l]	24 h[l]
Soluble reactive phosphates	Discrete sampler or pump	-	Plastic or glass[l]	Filter; refrigerate[h]	4°C[l]	24 h[l]
Extractable organic compounds (e.g., semivolatiles)	Discrete sampler or pump	4 L	Amber glass bottle[k]	pH < 2, 6N HCl; airtight seal; refrigerate	4°C[k]	7 days for extraction; 40 days for extract analysis[k]
Volatile organic compounds	Discrete sampler or pump	80 mL	Glass vial[k]	pH < 2 with 1:1 HCL; refrigerate in airtight, completely filled container[k]	4°C[k]	14 days for sample analysis if preserved[m]
Total phosphorus	Discrete sampler or pump	-	Plastic or glass[i]	H_2SO_4 to pH < 2; refrigerate	4°C[l]	7 days[l]
Total solids	Discrete sampler or pump	200 mL	Plastic or glass[l]	Refrigerate	4°C[l]	7 days[l]

Table 8-2 *(continued)*

Analyses	Collection Method[b]	Amount Required[c]	Container[d]	Preservation Technique	Storage Conditions	Holding times[e]
WATER AND ELUTRIATE (continued)						
Volatile solids	Discrete sampler or pump	200 mL	Plastic or glass[l]	Refrigerate	4°C[l]	7 days[l]
Sulfides	Discrete sampler or pump	-	Plastic or glass[l]	pH > 9 NaOH (ZnAc); refrigerate	4°C[l]	24 h[l]
Biological Tests						
Site water	Grab	Depends on tests being performed	Plastic carboy	Refrigerate	< 4°C	14 days
Dilution water	Grab or makeup	Depends on tests being performed	Plastic carboy	Refrigerate	<4°C	14 days
TISSUE						
Metals	Trawl/Teflon-coated grab	5-10 g	Double Ziploc[f]	Handle with nonmetallic forceps; plastic gloves; dry ice[f]	≤ -20°C[f] or freezer storage	Hg - 28 days Others - 6 months[n]
PCBs and chlorinated pesticides	Trawl/Teflon-coated grab	10-25 g	Hexane-rinsed double aluminum foil and double Ziploc[f]	Handle with hexane-rinsed stainless steel forceps; dry ice[f]	≤ -20°C[f] or freezer storage	14 days[h]
Volatile organic compounds	Trawl/Teflon-coated grab	10-25 g	Heat-cleaned aluminum foil and watertight plastic bag[m]	Covered ice chest[g]	≤ -20°C[h] or freezer storage	14 days[n]

Table 8-2 *(continued)*

Analyses	Collection Method[b]	Amount Required[c]	Container[d]	Preservation Technique	Storage Conditions	Holding times[e]
TISSUE (continued)						
Semivolatile organic compounds (e.g, PAH)	Trawl/Teflon-coated grab	10-25 g	Hexane-rinsed double aluminum foil and double Ziploc[f]	Handle with hexane-rinsed stainless steel forceps; dry ice[f]	≤ -20°C[f] or freezer storage	14 days[h]
Lipids	Trawl/Teflon-coated grab	part of organic analyses	Hexane-rinsed aluminum foil	Handle with hexane-rinsed stainless steel forceps; quick freeze	≤ -20°C or freezer storage	14 days[h]

[a] This table contains only a summary of collection, preservation, and storage procedures for samples. The cited references should be consulted for a more detailed description of these procedures.

[b] Collection method should include appropriate liners.

[c] Amount of sample required by the laboratory to perform the analysis (wet weight or volume provided, as appropriate). Miscellaneous sample size for sediment should be increased if auxiliary analytes that cannot be included as part of the organic or metal analyses are added to the list. The amounts shown are not intended as firm values; more or less tissue may be required depending on the analytes, matrices, detection limits and particular analytical laboratory.

[d] All containers should be certified as clean according to EPA (1990a).

[e] These holding times are for sediment, water, and tissue based on guidance that is sometimes administrative rather than technical in nature. There are no promulgated, scientifically based holding time criteria for sediments, tissues or elutriates. References should be consulted if holding times for sample extracts are desired. Holding times are from the time of sample collection.

[f] NOAA (1989)

[g] Tetra Tech (1986a)

[h] Sample may be held for up to one year if ≤ -20°C.

[i] Polypropylene should be used if phthalate bioaccumulation is of concern.

[j] Two weeks is recommended; sediments must not be held for longer than 8 weeks prior to biological testing.

[k] EPA (1987c); 40 CFR Part 136, Table III

[l] Plumb (1981)

[m] If samples are not preserved to pH<2, then aromatic compounds must be analyzed within 7 days.

[n] Tetra Tech (1986b)

- perform the necessary analyses
- partition the samples, either in the field or as soon as possible after sampling, for respective storage and/or analytical requirements (e.g., freezing for trace metal analysis, refrigeration for bioassays)
- provide sample for replicate or QA analyses, if specified
- archive portions of the sample for possible later analysis.

Sample handling is project and analysis specific as well as being based on what is practical and possible. Generally, samples to be analyzed for trace metals should not come into contact with metals, and samples to be analyzed for organic compounds should not come into contact with plastics. All sample containers should be appropriately cleaned (acid-rinsed for analysis of metals; solvent-rinsed for analysis of organic compounds).

For analysis of volatile compounds, samples should completely fill the storage container, leaving no air-space. These samples should be refrigerated but never frozen or the containers will crack. Samples for other kinds of chemical analysis are sometimes frozen. If the sample is to be frozen, sufficient air space should be allowed for expansion to take place. Container labels have to withstand soaking, drying, and freezing without becoming detached or illegible. The labelling system should be tested prior to use in the field.

Sediment samples for biological testing should have at least the larger living organisms removed from the sediment prior to testing. This may be accomplished by press-sieving the sediments through a 1-mm-mesh screen. Other matter retained on the screen with the organisms, such as shell fragments, gravel, and debris, should be recorded and discarded. Prior to use in bioassays, individual test sediments should be thoroughly homogenized with clean instruments (until color and textural homogeneity is achieved).

8.2.6.2 Sample Preservation

Preservation steps should be taken immediately upon sediment collection. There is no universal preservation or storage technique although storage in the dark at 4°C is generally used for all samples held for any length of time prior to partitioning, and for some samples after partitioning. A technique for one group of analyses may interfere with other analyses. This problem can be overcome by collecting sufficient sample volume to utilize specific preservation or storage techniques for specific analytes or

tests. Preservation, whether by refrigeration, freezing, or addition of chemicals, should be accomplished onboard the collecting vessel whenever possible. If final preservation techniques cannot be implemented in the field, the sample should be temporarily preserved in a manner that retains its integrity.

Onboard refrigeration is generally accomplished with coolers and ice; however, samples should be segregated from melting ice or cooling water. Samples which are to be frozen on board may be stored in an onboard freezer or may simply be placed in a cooler with dry ice or blue ice. Sediment samples for biological analysis should be preserved at 4°C, never frozen or dried. Additional guidance on sample preservation is given in Table 8-2.

8.2.6.3 Sample Storage

The elapsed time between sample collection and analysis should be as short as possible. Sample holding times for chemical evaluations are analysis-specific (Table 8-2). Sediments for bioassay (toxicity and/or bioaccumulation) testing *should* be tested as soon as possible, preferably within 2 weeks of collection. Studies to date suggest that sediment storage time should not exceed 8 weeks (at 4°C, in the dark, excluding air) (Becker and Ginn, 1990; Tatem et al., 1991). Toxicity may change with storage time. Sample storage conditions (e.g., temperature, location of samples) should be documented.

8.2.7 Logistical Considerations and Safety Precautions

A number of frustrations in sample collection and handling can be minimized by carefully thinking through the process and requirements before going to the field (e.g., see EPA, 1995). Contingency plans are essential. Well-trained, qualified, and experienced field crews should be used. Backup equipment and sampling gear, and appropriate repair parts, are advisable. A surplus of sampling containers and field data sheets should be available. Sufficient ice and adequate ice-chest capacity should be provided, and the necessity of replenishing ice before reaching the laboratory should be considered. A vessel with adequate deck space is safer and allows for more efficient work than an overcrowded vessel. Unforeseeable circumstances (e.g., weather delays) are to be expected during field sampling, and time to adequately accomodate the unforeseen has to be included in sampling schedules.

Appropriate safety and health precautions must be observed during field sampling activities. EPA (1984) should be used as a guidance document to prepare a site-specific health and safety plan. The health and safety plan should be prepared as a separate document from the QA project plan. Requirements set forth in the Occupational Safety and Health Administration 29 CFR § 1910.120 (Federal Register, Vol. 54, No. 43) should be met for medical surveillance, personal protection, respirator fit testing (if applicable),

and hazardous waste operations training (if applicable) by all personnel working in contaminated areas or working with contaminated media.

The procedures and practices established in the site-specific health and safety plan must be observed by all individuals participating in the field activities. Safety requirements should also be met by all observers present during field audits and inspections. The plan should include the following information:

- site location and history
- scope of work
- site control
- hazard assessment (chemical and physical hazards)
- levels of protection and required safety equipment
- field monitoring requirements
- decontamination
- training and medical monitoring requirements
- emergency planning and emergency contacts.

Samples must be properly disposed when no longer needed. Ordinary sample-disposal methods are usually acceptable, and special precautions are seldom appropriate. Under Federal law [40 CFR 261.5(a)], where highly contaminated wastes are involved, if the waste generated is less than 100 Kg per month, the generator is conditionally exempt as a small-quantity generator and may accumulate up to 1,000 Kg of waste on the property without being subject to the requirements of Federal hazardous waste regulations. However, State and local regulations may require special handling and disposal of contaminated samples. When samples have to be shipped, 49 CFR 100-177 should be consulted for current Department of Transportation regulations on packing and shipping.

8.2.8 Non-Indigenous Test Species

Over the last few years, there has been a growing awareness of the ecological and economic damage caused by introduced species. Because both east and west coast species are often used in bioaccumulation

tests, there is a real potential of introducing bioaccumulation test species or associated fauna and flora (e.g., pathogens, algae used in transporting the worms). It is the responsibility of the persons conducting the bioaccumulation or toxicity tests to assure that no non-indigenous species are released.

The general procedures to contain non-indigenous species are to collect and then poison all water, sediment, organisms and associated packing materials (e.g., algae, sediment) before disposal. Chlorine bleach can be used as the poison. A double containment system is used to keep any spillage from going down the drain. Guidance on procedures used in toxicity tests can be found in Appendix B of DeWitt et al. (1992a). Flow-through tests can generate large quantities of water, and researchers should plan on having sufficient storage facilities.

9.0 PHYSICAL ANALYSIS OF SEDIMENT AND CHEMICAL ANALYSIS OF SEDIMENT, WATER, AND TISSUE SAMPLES

This section provides guidance on the selection of chemical and physical analyses to aid in the evaluation of dredged material for proposed disposal, and on the methods used to analyze these parameters. QA/QC guidance is provided in Appendix G and EPA (1995).

The methods cited in this section may be used to develop the required chemical information. However, other methods may provide similar results, and the final choice of analytical procedures depends upon the needs of each evaluation. In all cases, proven, state-of-the-art methods should be used.

Any dredged material from estuarine or marine areas contains salt. The salt can interfere with the results obtained from some analytical methods. *Any methods proposed for the analysis of sediment and water from estuarine or marine environments must explicitly address steps taken to control salt interference.*

9.1 Physical Analysis of Sediment

Physical characteristics of the dredged material must be determined to help assess the impact of disposal on the benthic environment and the water column at the disposal site. This is the first step in the overall process of sediment characterization, and also helps to identify appropriate control and reference sediments for biological tests. In addition, physical analyses can be helpful in evaluating the results of analyses and tests conducted later in the characterization process.

The general analyses may include (1) grain size, (2) total solids and (3) specific gravity.

Grain-size analysis defines the frequency distribution of the size ranges of the particles that make up the project sediment (e.g., Plumb, 1981; Folk, 1980). The general size classes of gravel, sand, silt, and clay are the most useful in describing the size distribution of particles in dredged-material samples. Use of the Unified Soil Classification System (USCS) for physical characterization is recommended for the purpose of consistency with USACE engineering evaluations (ASTM, 1992).

Total solids is a gravimetric determination of the organic and inorganic material remaining in a sample after it has been dried at a specified temperature. The total solids values generally are used to convert concentrations of contaminants from a wet weight to a dry weight basis.

The specific gravity of a sample is the ratio of the mass of a given volume of material to an equal volume of distilled water at the same temperature (Plumb, 1981). The specific gravity of a dredged-material sample helps to predict the behavior (i.e., dispersal and settling characteristics) of dredged material after disposal.

Other physical/engineering properties (e.g., Atterburg limits, hydrometer analysis, settling properties, etc.) may be needed to evaluate the quality of any effluent discharged from confined disposal facilities. Guidance in this regard is provided in Appendix B.

9.2 Target Detection Limits

The selection of appropriate target detection limits (TDLs) is vital (e.g., TetraTech, 1986a; EPA, 1986a). TDLs should be lower than the appropriate values against which the data are to be compared for interpretation. Different analytical methods are capable of detecting different concentrations of a chemical in a sample. For example, a highly sensitive technique can detect a much lower chemical concentration than can a screening technique for the same chemical. The accuracy of measurements also differs among analytical techniques. In general, as the sensitivity and accuracy of a technique increases, so does the cost. Recommended TDLs that are judged to be feasible, cost effective, and to meet the requirements for dredged material evaluations are summarized in EPA (1995), along with example analytical methods that are capable of meeting those TDLs. However, any method that can achieve those TDLs is acceptable, provided that the appropriate documentation of the method performance is generated for the project.

The TDL is a performance goal set between the lowest, technically feasible detection limit for routine analytical methods and available regulatory criteria or guidelines for evaluating dredged material. The TDL is, therefore, equal to or greater than the lowest amount of a chemical that can be reliably detected based on the variability of the blank response of routine analytical methods (see EPA [1995] for discussion of method blank response). However, the reliability of a chemical measurement generally increases as the concentration increases. Analytical costs may also be lower at higher detection limits. For these reasons, the TDLs in EPA (1995) have been set at not less than 10 times lower than available regional or international dredged material guidelines for potential biological effects associated with sediment chemical contamination.

All data generated for dredged material evaluation should meet the TDLs in EPA (1995) unless prevented by sample-specific interferences. Any sample-specific interferences must be well documented by the laboratory. If significantly higher or lower TDLs are required to meet rigorously defined data quality

objectives (e.g., for human health risk assessments) for a specific project then, on a project-specific basis, modification to existing analytical procedures may be necessary. Such modifications must be documented in the QA project plan. An experienced analytical chemist should be consulted so the most appropriate method modifications can be assessed, the appropriate coordination with the analytical laboratory can be implemented, and the data quality objectives can be met. A more detailed discussion of method modifications is provided in EPA (1995).

9.3 Chemical Analysis of Sediment

9.3.1 Target Analytes

Chemical analysis provides information about the chemicals present in the dredged material that, if biologically available, could cause toxicity and/or be bioaccumulated. This information is valuable for exposure assessment and for deciding which of the contaminants present in the dredged material to measure in tissue samples.

If the historical review conducted in Tier I (Section 4.1) establishes a reason to believe that sediment contaminants may be present, but fails to produce sufficient information to develop a definitive list of potential contaminants, a list of target analytes has to be compiled. Target analytes should be selected from, but not necessarily limited to, the compounds in Table 9-1 and from the historical review information. The target list should include contaminants that historical information or commercial and/or agricultural applications suggest could be present at a specific dredging site — for example, tributyltin near shipyards, berthing areas, and marinas where these compounds have been applied. Analysis of polynuclear aromatic hydrocarbons (PAH) in dredged material should focus on those PAH compounds that are on the priority pollutant list (Clarke and Gibson, 1987).

All PCB analyses should be made using congener-specific methods. The sum of the concentrations of specific congeners is an appropriate measure of total PCBs (NOAA, 1989).

Sediments should be analyzed for total organic carbon (TOC). This is particularly important if there are hydrophobic organics on the contaminant of concern list developed in Tier I. The TOC content of sediment is a measure of the total amount of oxidizable organic material in a sample and also affects contaminant bioaccumulation by, and effects to, organisms (e.g., Di Toro et al., 1991; DeWitt et al., 1992b).

Table 9-1. Potential Contaminants of Concern Listed According to Structural Compound Class.

Structural Compound Class	Contaminant
Phenols	phenol
	2,4-dimethylphenol
	2-methylphenol
	4-methylphenol
Substituted Phenols	2,4,6-trichlorophenol
	para-chloro-meta-cresol
	2-chlorophenol
	2,4-dichlorophenol
	2-nitrophenol
	4-nitrophenol
	2,4-dinitrophenol
	4,6-dinitro-*o*-cresol
	pentachlorophenol
Organonitrogen Compounds	benzidine
	3,3'-dichlorobenzidine
	2,4-dinitrotoluene
	2,6-dinitrotoluene
	1,2-diphenylhydrazine
	nitrobenzene
	N-nitrosodimethylamine
	N-nitrosodiphenylamine
	N-nitrosodipropylamine
Low Molecular Weight Polynuclear Aromatic Hydrocarbons (PAH)	acenaphthene
	naphthalene
	acenaphthylene
	anthracene
	phenanthrene
	fluorene
	1-methylnapthalene
	2-methylnapthalene
High Molecular Weight Polynuclear Aromatic Hydrocarbons (PAH)	fluoranthene
	benzo*(a)*anthracene
	benzo*(a)*pyrene
	benzo*(b)*fluoranthene
	benzo*(k)*fluoranthene
	chrysene
	benzo*(ghi)*perylene
	dibenzo*(a,h)*anthracene
	ideno(1,2,3-*cd*)pyrene
	pyrene
Chlorinated Aromatic Hydrocarbons	1,2,4-trichlorobenzene
	hexachlorobenzene
	2-chloronaphthalene
	1,2-dichlorobenzene
	1,3-dichlorobenzene
	1,4-dichlorobenzene
Chlorinate Aliphatic Hydrocarbons	hexachlorobutadiene
	hexachloroethane
	hexachlorocyclopentadiene
Halogenated Ethers	bis(2-chloroethyl)ether
	4-chlorophenyl ether
	4-bromophenyl ether
	bis(2-chloroisopropyl) ether
	bis(2-chlorethoxy)methane
Phthalates	bis(2-ethylhexyl)phthalate
	butyl benzyl phthalate
	di-*n*-butyl phthalate
	di-*n*-octyl phthalate
	diethyl phthalate
	dimethyl phthalate
Polychlorinated Biphenyls (PCB) as Aroclors[a]	PCB-1242
	PCB-1254
	PCB-1221
	PCB-1232
	PCB-1248
	PCB-1260
	PCB-1016
Miscellaneous Oxygenated Compounds	TCDD (dioxin)[b]
	PCDF (furan)
	isophorone
Pesticides	aldrin
	dieldrin
	chlordane
	chlorbenside
	dacthal
	DDT[c]
	endosulfan[d]
	endrin
	endrin aldehyde
	heptachlor
	heptachlor epoxide
	α-hexachlorocyclohexane
	β-hexachlorocyclohexane
	δ-hexachlorocyclohexane
	γ-hexachlorocyclohexane
	toxaphene
	mirex
	methoxychlor
	parathion
	malathion
	guthion
	demeton

Table 9-1. *(continued)*

Structural Compound Class	Contaminant
Volatile Halogenated Alkanes	tetrachloromethane
	1,2-dichloroethane
	1,1,1-trichloroethane
	1,1-dichloroethane
	1,1,2-trichloroethane
	1,1,2,2-tetrachloroethane
	chloroethane
	chloroform
	1,2-dichloropropane
	dichloromethane
	chloromethane
	bromomethane
	bromoform
	dichlorobromoethane
	fluorotrichloromethane
	dichlorodifluoromethane
	chlorodibromomethane
Volatile Halogenated Alkenes	1,1-dichlorethylene
	1,2-*trans*-dichlorethylene
	trans-1,3-dichloropropene
	cis-1,3-dichloropropene
	tetrachlorethene
	trichlorethene
	vinyl chloride
Volatile Aromatic Hydrocarbons	benzene
	ethylbenzene
	toluene
Chlorinated Benzenes	1,3-dichlorobenzene
	1,4-dichlorobenzene
	1,2-dichlorobenzene
	1,2,4-trichlorobenzene
	hexachlorobenzene
Volatile Unsaturated Carbonyl Compounds	acrolein
	acrylonitrile
Volatile Ethers	2-chlorethylvinylether
	bis(chloromethyl)ether
Metals	aluminum
	antimony
	arsenic
	beryllium
	butyltins
	cadmium
	chromium (hexavalent)
	cobalt
	copper
	iron
	lead
	manganese
	mercury
	nickel
	selenium
	silver
	thallium
	tin
	zinc
Miscellaneous	ammonia[e]
	asbestos
	benzoic acid
	cyanide
	guaiacols
	methylethyl ketone
	resin acids

[a]It is recommended that PCB analyses use congener-specific methods. The sum of the concentrations of specific congeners is an appropriate measure of total PCBs (see Table 9-3).
[b]Additional dioxin and furan (e.g., TCDF) compounds are listed in Table 9-2.
[c]Includes DDT, DDD, and DDE
[d]Includes ∝-endosulfan, β-endosulfan, and endosulfan sulfate.
[e]Ammonia may not be a contaminant of concern at certain open-water dredged material disposal sites (e.g., dispersive situations and situations with well-oxygenated overlying water).

Sediments in which metals are suspected to be contaminants of concern may also be analyzed for acid volatile sulfide (AVS) (Di Toro et al., 1990; EPA, 1991a). Although acceptable guidance on the interpretation of AVS measurements is not yet available, and AVS measurements are not generally recommended at this time, such measurements can provide information on the bioavailability of metals in anoxic sediments. Presently, AVS studies represent an area of on-going research which may be formally included in the manual if and when decision criteria are determined.

9.3.2 Selection of Analytical Techniques

Once the list of target analytes for sediments has been established, analytical methods have to be determined. The methods will, to some degree, dictate the amount of sediment sample required for each analysis. General sample sizes are provided in Table 8-2, and include possible requirements for more than one analysis for each group of analytes. The amount of sample used in an analysis affects the detection limits attainable by a particular method.

TOC analyses should be based on high-temperature combustion rather than on chemical oxidation. Some classes of organic compounds are not fully degraded by chemical/ultraviolet techniques. The volatile and nonvolatile organic components make up the TOC of a sample. Because inorganic carbon (e.g., carbonates and bicarbonates) can be a significant proportion of the total carbon in some sediment, the sample has to be treated with acid to remove the inorganic carbon prior to TOC analysis. The method of Plumb (1981) recommends HCl as the acid. An alternative choice might be sulfuric acid since it is nonvolatile, is used as the preservative, and does not add to the chloride burden of the sample. Whatever acid is used, it has to be demonstrated on sodium chloride blanks that there is no interference generated from the combined action of acid and salt in the sample. Acceptable methods for TOC analysis are available from EPA (1995).

For many metals analyses in marine/estuarine areas, the concentration of salt may be much greater than the analyte of interest and can cause unacceptable interferences in certain analytical techniques. In such cases, the freshwater approach of acid digestion followed by inductively coupled plasma-atomic emission spectrometry (ICP) or graphite furnace atomic absorption spectroscopy (GFAAS) should be coupled with appropriate techniques for controlling this interference. The Hg method in EPA (1986a; Method 7471) may be used for the analysis of Hg in sediment. Tributyltin may be analyzed by the method of Rice et al. (1987), and selenium and arsenic by the method of EPRI (1986). A total extraction of metal ions is neither necessary nor desirable for dredged material evaluations. The standard aqua regia extraction yields consistent and reproducible results.

The recommended method for analysis of semivolatile and volatile priority pollutants in sediment is described by Tetra Tech (1986a). Analysis for organic compounds should always use capillary-column gas chromatography (GC): gas chromatography/mass spectrometry (GC/MS) techniques for semi-volatile and volatile priority pollutants, and dual column gas chromatography/electron-capture detection (GC/ECD) for pesticides and PCBs (NOAA, 1989). Alternatively, GC/MS using selected ion monitoring can be used for PCB and pesticide analysis. These analytically sound techniques yield accurate data on the concentrations of chemicals in the sediment matrix. The analytical techniques for semivolatile organic compounds generally involve solvent extraction from the sediment matrix and subsequent analysis, after cleanup, using GC or GC/MS. Extensive cleanup is necessitated by the likelihood of (1) biological macromolecules, (2) sulfur from sediments with low or no oxygen, and (3) oil and/or grease in the sediment. The analysis of volatile organic compounds incorporates purge-and-trap techniques with analysis by either GC or GC/MS. If dioxin (i.e., 2,3,7,8, - TCDD) analysis is being performed, the methods of Kuehl et al. (1987), Smith et al. (1984), EPA (1989b; Method 8290), or EPA (1990c; Method 1613) and summary in EPA (1995) should be consulted. EPA Method 1613 is the recommended procedure for measuring the tetra- through octa- chlorinated dibenzo-p-dioxins (PCDDs) and dibenzofurans (PCDFs). This method has been developed for analysis of water, soil, sediment, sludge, and tissue. Table 9-2 shows the 17 compounds determined by Method 1613.

Techniques for analysis of chemical constituents have some inherent limitations for sediment samples. Interferences encountered as part of the sediment matrix, particularly in samples from heavily contaminated areas, may limit the ability of a method to detect or quantify some analytes. The most selective methods using GC/MS techniques are recommended for all nonchlorinated organic compounds because such analysis can often avoid problems due to matrix interferences. Gas chromatography/electron-capture detection (GC/ECD) methods are recommended as the primary analytical tool for all PCB and pesticide analyses because GC/ECD analysis will result in lower detection limits. The analysis and identification of PCBs by GC/ECD methods are based upon relative retention times and peak shapes. Matrix interferences may result in the reporting of false negatives, although congener-specific PCB analysis reduces this concern relative to use of the historical Aroclor® matching procedure.

PCBs have traditionally been quantified with respect to Aroclor® mixtures. This procedure can result in errors in determining concentrations (Brown et al., 1984). For dredged material evaluations, the concentration of total PCBs should be determined by summing the concentrations of specific individual PCB congeners identified in the sample (see Table 9-3). The minimum number of PCB congeners that should be analyzed are listed in the first column of Table 9-3 (i.e., "summation" column) (NOAA, 1989). This summation is considered the most accurate representation of the PCB concentration in samples. Additional PCB congeners are also listed in Table 9-3. McFarland and Clarke (1989) recommend these PCB congeners for analysis based on environmental abundance, persistence, and biological importance.

Table 9-2. PCDD and PCDF Compounds Determined by Method 1613

Native Compound[1]
2,3,7,8-TCDF
2,3,7,8-TCDD
1,2,3,7,8-PeCDF
2,3,4,7,8-PeCDF
1,2,3,7,8-PeCDD
1,2,3,4,7,8-HxCDF
1,2,3,6,7,8-HxCDF
2,3,4,6,7,8-HxCDF
1,2,3,4,7,8-HxCDD
1,2,3,6,7,8-HxCDD
1,2,3,7,8,9-HxCDD
1,2,3,7,8,9-HxCDF
1,2,3,4,6,7,8-HpCDF
1,2,3,4,6,7,8-HpCDD
1,2,3,4,7,8,9-HpCDF
OCDD
OCDF

[1] Polychlorinated dioxins and furans:

TCDD = Tetrachlorodibenzo-p-dioxin
TCDF = Tetrachlorodibenzofuran
PeCDD = Pentachlorodibenzo-p-dioxin
PeCDF = Pentachlorodibenzofuran
HxCDD = Hexachlorodibenzo-p-dioxin
HxCDF = Hexachlorodibenzofuran
HpCDD = Heptachlorodibenzo-p-dioxin
HpCDF = Heptachlorodibenzofuran
OCDD = Octachlorodibenzo-p-dioxin
OCDF = Octachlorodibenzofuran

Table 9-3. Polychlorinated Biphenyl (PCB) Congeners Recommended for Quantitation as Potential Contaminants of Concern.

PCB Congener[a]	Congener Number[b]		
	Summation[c]	Highest Priority[d]	Second Priority[e]
2,4' diCB	8		
2,2',5 triCB	18		18
2,4,4' triCB	28		
3,4,4' triCB			37
2,2',3,5' tetraCB	44		44
2,2',4,5' tetraCB			99
2,2',5,5' tetraCB	52		52
2,3',4,4' tetraCB	66		
2,3',4',5 tetraCB			70
2,4,4',5 tetraCB			74

(continued)

Table 9-3. *(continued)*

PCB Congener[a]	Congener Number[b]		
	Summation[c]	Highest Priority[d]	Second Priority[e]
2,2',3,3',4,4',5,6 octaCB		195	
2,2',3,3',4,5,5',6' octaCB			201
2,2',3,3',4,4',5,5',6 nonaCB		206	
2,2',3,3',4,4',5,5',6,6' decaCB		209	

[a]PCB congeners recommended for quantitation, from dichlorobiphenyl (diCB) through decachlorobiphenyl (decaCB).

[b]Congeners are identified by their International Union of Pure and Applied Chemistry (IUPAC) number, as referenced in Ballschmiter and Zell (1980) and Mullin et al. (1984).

[c]These congeners are summed to determine total PCB concentration following the approach in NOAA (1989).

[d]PCB congeners having highest priority for potential environmental importance based on potential for toxicity, frequency of occurrence in environmental samples, and relative abundance in animal tissues (McFarland and Clarke, 1989).

[e]PCB congeners having second priority for potential environmental importance based on potential for toxicity, frequency of occurrence in environmental samples, and relative abundance in animal tissues (McFarland and Clarke, 1989).

[f]To separate PCBs 126 and 169, it is necessary to initially utilize an enrichment step with an activated carbon column (Smith, 1981).

McFarland et al. (1986) note that the most toxic PCB congeners lie mainly within the tetra-, penta-, and hexa- chlorobiphenyl groups. Sample preparation for PCB congener analysis should follow the techniques described by Tetra Tech (1986a) or EPA (1986a), but with instrumental analysis and quantification using standard capillary GC columns on individual PCB isomers according to the methods reported by NOAA (1989) (see also Dunn et al., 1984; Schwartz et al., 1984; Mullin et al., 1984; Stalling et al., 1987).

Although the methods mentioned above are adequate for detecting and quantifying concentrations of those PCB congeners comprising the majority of total PCBs in environmental samples, they are not appropriate for separating and quantifying PCB congeners which may coelute with other congeners and/or may be present at relatively small concentrations in the total PCB mixture. Included in this latter group of compounds, for example, are PCBs 126 and 169, two of the more toxic nonortho-substituted (coplanar) PCB congeners (Table 9-3). In order to separate these (and other toxic nonortho-substituted congeners), it is necessary to initially utilize an enrichment step with an activated carbon column (Smith, 1981). Various types of carbon columns have been used, ranging from simple gravity columns (e.g., in a Pasteur pipette) to more elaborate (and efficient) columns using high pressure liquid chromatography (HPLC) systems (see Schwartz et al., 1993). The preferred method of separation and quantitation of the enriched PCB mixture has been via high resolution GC-MS with isotope dilution (Kuehl et al., 1991; Ankley et al., 1993; Schwartz et al., 1993). However, recent studies have shown that if the carbon enrichment is done via HPLC, the nonortho-substituted PCB congeners of concern also may be quantifiable via more widely available GC/ECD systems (Schwartz et al., 1993).

The overall toxicity of nonortho-substituted PCBs at a site can be assessed based on a comparison with the toxicity of 2,3,7,8-tetrachloro-dibenzo-p-dioxin (TCDD). A similar procedure can be used for assessing the toxicity of a mixture of dioxins and furans. In this "toxicity equivalency factor" (TEF) approach, potency values of individual congeners (relative to TCDD) and their respective sediment concentrations are used to derive a "summed" 2,3,7,8-TCDD equivalent (TCDD-EQ) (EPA, 1989c; Table 9-4). Ankley et al. (1992b) provide an example of the use of this approach.

TEFs have been derived for human health purposes. For aquatic organisms the relative toxicities of different PCB congeners and dioxins are likely to be quite different. For instance, wildlife or fish TEF for PCBs are not equivalent to those for humans (Walker et al., 1992).

To ensure that contaminants not included in the list of target analytes are not overlooked in the chemical characterization of the dredged material, the analytical results should also be scrutinized by trained personnel. The presence of persistent major unknown analytes should be noted. Methods involving GC/MS techniques for organic compounds are recommended for the identification of any unknown analytes.

Table 9-4. Methodology for Toxicity Equivalency Factors

Because toxicity information on some dioxin and furan species is scarce, a structure-activity relationship has been assumed. The toxicity of each congener is expressed as a fraction of the toxicity of 2,3,7,8 TCDD.

Compound	TEF
2,3,7,8 TCDD	1
other TCDD	0
2,3,7,8-PeCDDs	0.5
other PeCDDs	0
2,3,7,8-HxCDDs	0.1
other HxCDDs	0
2,3,7,8-HpCDDs	0.01
other HpCDDs	0
OCDD	0.001
2,3,7,8-TCDF	0.1
other TCDFs	0
1,2,3,7,8-PeCDF	0.05
2,3,4,7,8-PeCDF	0.5
other PeCDFs	0
2,3,7,8-HxCDFs	0.1
other HxCDFs	0
2,3,7,8-HpCDFs	0.01
other HpCDFs	0
OCDF	0.001

9.4 Chemical Analysis of Water

9.4.1 Analytical Targets

Analysis to determine the potential release of dissolved contaminants from the dredged material (standard elutriate) may be necessary to make a factual determination. Elutriate tests (Section 10.1.2.1) involve mixing dredged material with dredging site water and allowing the mixture to settle. The portion of the dredged material that is considered to have the potential to impact the water column is the supernatant remaining after undisturbed settling and centrifugation. Chemical analysis of the elutriate allows a direct comparison, after allowance for mixing, to applicable water quality standards (WQS). When collecting samples for elutriate testing, consideration should be given to adequate volumes of water and sediment required to prepare samples for analysis including replicates where appropriate. In some instances, when there is poor settling, the elutriate preparation has to be performed successively several times to accumulate enough water for testing.

Historical water quality information from the dredging site (Tier I) should be evaluated along with data obtained from the chemical analysis of sediment samples to select target analytes. Chemical evaluation of the dredged material provides a known list of constituents which might affect the water column. All target analytes identified in the sediment should initially be considered potential targets for water analysis. Nonpriority-pollutant chemical components which are found in measurable concentrations in the sediments should be included as targets if review of the literature indicates that these analytes have the potential to bioaccumulate in animals [i.e., have a high K_{ow} or bioconcentration factor (BCF)] and/or are of toxicological concern.

9.4.2 Analytical Techniques

In contrast to freshwater, there generally are no EPA approved methods for analysis of saline water although widely accepted methods have existed for some time (e.g., Strickland and Parsons, 1972; Grasshoff et al., 1983; Parsons et al., 1984). Application of the freshwater methods to saltwater will frequently result in higher detection limits than are common for freshwater unless care is taken to control the effects of salt on the analytical signal. Modifications or substitute methods (e.g., additional extract concentration steps, larger sample sizes, or concentration of extracts to smaller volumes) might be necessary to properly determine analyte concentration in seawater or to meet the desired target detection limits (TDLs). It is extremely important to ascertain a laboratory's ability to execute methods and attain acceptable detection limits in matrices containing up to 3% sodium chloride.

Once the list of target analytes for water has been established, analytical methods have to be determined. The water volume required for specific analytical methods may vary. A minimum of 1 L of elutriate should be prepared for metals analysis (as little as 100 mL may be analyzed). One liter of elutriate should be analyzed for organic compounds. Sample size should also include the additional volume required for the matrix spike and matrix spike duplicate analyses required as part of the analytical procedure. Samples from the dredging site and, where appropriate, disposal site, should be delivered for organic and metals analysis. Sample size is one of the limiting factors in determining detection limits for water analyses, but TDLs below the WQS must be the goal in all cases. Participating laboratories should routinely report detection limits achieved for a given analyte.

Detailed methods for the analysis of organic and inorganic priority pollutants in water are referenced in 40 CFR 136 and in EPA (1983). Additional approved methods include EPA (1986a,b; 1988a,b,c; 1990b,c); APHA (1989); ASTM (1991b); Tetra Tech (1985). Most of these methods will require modification to achieve low detection limits in saline waters. Analysis of the semivolatile organic priority pollutants involves a solvent extraction of water with an optional sample cleanup procedure and analysis using GC or GC/MS. The volatile priority pollutants are determined by using purge-and-trap techniques and are analyzed by either GC or GC/MS. If dioxin (i.e., 2,3,7,8, - TCDD) analysis is necessary, Kuehl et al. (1987), Smith et al. (1984), EPA (1989b; Method 8290), or EPA (1990c; Method 1613) should be consulted. EPA Method 1613 is the recommended procedure for measuring the tetra- through octa-PCDDs and PCDFs.

A primary requirement for analysis of inorganic and organic priority pollutants is to obtain detection limits which will result in usable, quantitative data that can subsequently be compared against applicable WQS to determine compliance with the water quality certification requirement under Section 401. Existing EPA methods for freshwater analysis need to be adapted to achieve environmentally meaningful detection limits in saline waters because of matrix interferences caused by salt. For example, it is recommended that sample extracts be concentrated to the lowest possible volume prior to instrumental analysis, and that instrumental injection volumes be increased to lower the detection limits. All PCB and pesticide analytes should be analyzed by using GC/ECD, since the GC/ECD methods are more sensitive to these compounds and will lower the detection limits. PCBs should be quantified as specific congeners (Mullin et al., 1984; Stalling et al., 1987) and as total PCBs based on the summation of particular congeners (NOAA, 1989).

Analysis of saline water for metals is subject to matrix interferences from salts, particularly sodium and chloride ions, when the samples are concentrated prior to instrumental analysis. The gold-amalgamation method using cold-vapor atomic absorption spectrophotometry (AAS) analysis is recommended to eliminate saline water matrix interferences for mercury analysis. Methods using solvent extraction and

AAS analysis may be required to reduce saline water matrix interferences for other target metals. Other methods appropriate for metals include: cadmium, copper, lead, iron, zinc, silver (Danielson et al., 1978); arsenic (EPRI, 1986); selenium and antimony (Sturgeon et al., 1985); low levels of mercury (Bloom et al., 1983); and, tributyltin (Rice et al., 1987). Graphite-furnace AAS techniques after extraction are recommended for the analysis of metals, with the exception of mercury.

9.5 Chemical Analysis of Tissues

9.5.1 Target Analytes

Bioaccumulation is evaluated by analyzing tissues of test organisms for contaminants determined to be of concern for a specific dredged material. Sediment contaminant data and available information on the bioaccumulation potential of those analytes have to be interpreted to establish target compounds.

The *n*-octanol/water partition coefficient (K_{ow}) is used to estimate the BCFs of chemicals in organism/water systems (Chiou et al., 1977; Kenaga and Goring, 1980; Veith et al., 1980; Mackay, 1982). The potential for bioaccumulation generally increases as K_{ow} increases, particularly for compounds with log K_{ow} less than approximately 6. Above this value, there is less of a tendency for bioaccumulation potential to increase with increasing K_{ow}. Consequently, the relative potential for bioaccumulation of organic compounds can be estimated from the K_{ow} of the compounds. EPA (1985) recommends that compounds for which the log K_{ow} is greater than 3.5 be considered for further evaluation of bioaccumulation potential. The organic compound classes of priority pollutants with the greatest potential to bioaccumulate are PAHs, PCBs, pesticides, and some phthalate esters. Generally, the volatile organic, phenol, and organonitrogen priority pollutants are not readily bioaccumulated, but exceptions include the chlorinated benzenes and the chlorinated phenols. Table 9-5 provides data for organic priority pollutants based on K_{ow}. Specific target analytes for PCBs and PAHs are discussed in Section 9.3.1. The water content and percent lipids should be routinely determined as part of tissue analyses for organic contaminants.

Table 9-6 ranks the bioaccumulation potential of the inorganic priority pollutants based on calculated BCFs. Dredged material contaminants with BCFs greater than 1,000 (log BCF >3) should be further evaluated for bioaccumulation potential.

Tables 9-5 and 9-6 should be used with caution because they are based on calculated bioconcentration from water. Sediment bioaccumulation tests, in contrast, are concerned with accumulation from a complex medium via all possible routes of uptake. The appropriate use of the tables is to help in selecting

Table 9-5. Octanol/Water Partition Coefficients (K_{ow}) for Organic Compound Priority Pollutants and 301(h) Pesticides[a].

Pollutant	Octanol/Water Partition Coefficient (log K_{ow})	Pollutant	Octanol/Water Partition Coefficient (log K_{ow})
Di-*n*-octyl phthalate	9.2	Acenaphthylene	4.1

contaminants of concern for bioaccumulation analysis by providing a general indication of the relative potential for various chemicals to accumulate in tissues.

The strategy for selecting contaminants for tissue analysis should include three considerations, all of which are related to regulatory concern:

- the target analyte is a contaminant of concern and is present in the sediment as determined by sediment chemical analyses
- the target analyte has a high potential to accumulate and persist in tissues
- the target analyte is of toxicological concern.

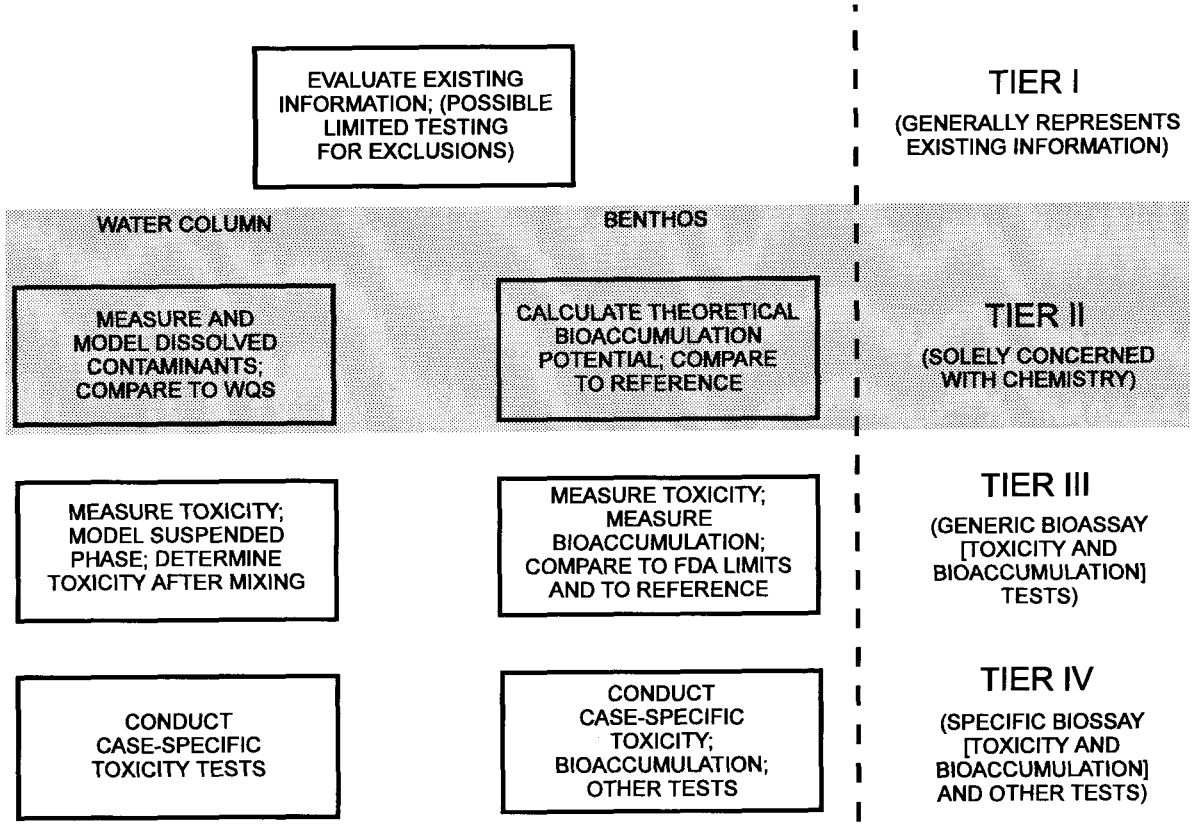
Contaminants with a lower potential to bioaccumulate, but which are present at high concentrations in the sediments, should also be included in the target list because bioavailability can increase with concentration. Conversely, contaminants with a high accumulation potential and of high toxicological concern should be considered as targets, even if they are only present at low concentrations in the sediment. Nonpriority-pollutant contaminants which are found in measurable concentrations in the sediments should be included as targets for tissue analysis if they have the potential to bioaccumulate and persist in tissues, and are of toxicological concern.

9.5.2 Analytical Techniques

At present, formally approved standard methods for the analysis of priority pollutants and other contaminants in tissues are not available. However, studies conducted for EPA and other agencies have developed analytical methods capable of identifying and quantifying most organic and inorganic priority pollutants in tissues. The amount of tissue required for analysis is dependent on the analytical procedure and the tissue moisture content. General guidance, but *not* firm recommendations, for the amount of tissue required, is provided in Table 8-2. The required amounts may vary depending on the analytes, matrices, detection limits, and particular analytical laboratory. Tissue moisture content must be determined for each sample to convert applicable data from a wet-weight to a dry-weight basis, however both wet- and dry-weight data should be reported.

Detection limits depend on the sample size as well as the specific analytical procedure. TDLs should be determined for all analytes according to initial guidance in 40 CFR 136 and more definitive guidance in

EPA (1995; cf. Section 9.2). Detection limits should be specified based on the intended use of the data and specific needs of each evaluation.



Existing methods for priority pollutant tissue analysis involve two separate procedures: one for organic compounds and another for metals. The recommended methods for the analysis of semivolatile organic pollutants are described in NOAA (1989). The procedure involves serial extraction of homogenized tissue samples with methylene chloride, followed by alumina and gel-permeation column cleanup procedures that remove coextracted lipids. An automated gel-permeation procedure described by Sloan et al. (1993) is recommended for rapid, efficient, reproducible sample cleanup. The extract is concentrated and analyzed for semivolatile organic pollutants using GC with capillary fused-silica columns to achieve sufficient analyte resolution. If dioxin (i.e., 2,3,7,8-TCDD) analysis is being performed, the methods of Mehrle et al. (1988), Kuehl et al. (1987), Smith et al. (1984), EPA (1989b; Method 8290), or EPA (1990c; Method 1613) should be consulted. EPA Method 1613 is the recommended procedure for measuring the tetra- through octa-PCDDs and PCDFs.

Chlorinated hydrocarbons (e.g., PCBs and chlorinated pesticides) should be analyzed by GC/ECD. PCBs should be quantitated as specific congeners (Mullin et al., 1984; Stalling et al., 1987) and not by industrial formulations (e.g., aroclors) because the levels of PCBs in tissues result from complex processes, including selective accumulation and metabolism (see the discussion of PCBs in Section 9.3.2). Lower detection limits and positive identification of PCBs and pesticides can be obtained by using chemical ionization mass spectrometry.

The same tissue extract is analyzed for other semivolatile pollutants (e.g., PAHs, phthalate esters, nitrosamines, phenols, etc.) using GC/MS as described by NOAA (1989), Battelle (1985), and Tetra Tech (1986b). These GC/MS methods are similar to EPA Method 8270 for solid wastes and soils (EPA, 1986a). Lowest detection limits are achieved by operating the mass spectrometer in the SIM mode. Decisions to perform analysis of nonchlorinated hydrocarbons and resulting data interpretation should consider that many of these analytes are readily metabolized by most fish and many invertebrates. Analytical methods for analysis of tissue samples for volatile priority pollutants are found in Tetra Tech (1986b).

Tissue lipid content is of importance in the interpretation of bioaccumulation information. A lipid determination should be performed on biota submitted for organic analysis if: (1) food chain models will be used; (2) test organisms could spawn during the test; (3) special circumstances occur (Tier IV), such as those requiring risk assessment. Bligh and Dyer (1959) provide an acceptable method, and the various available methods are evaluated by Randall et al. (1991).

Analysis for priority pollutant metals involves a nitric acid or nitric acid/perchloric acid digestion of the tissue sample and subsequent analysis of the acid extract using AAS or inductively coupled plasma-atomic emission spectrometry (ICP) techniques. Procedures in Tetra Tech (1986b) and EPA (1991c) are generally recommended. NOAA (1989) methods may also be used and are recommended when low detection levels are required. Microwave technology may be used for tissue digestion to reduce contamination and to improve recovery of metals (Nakashima et al., 1988). This methodology is consistent with tissue analyses performed by NOAA (1989), except for the microwave heating steps. Mercury analysis requires the use of cold-vapor AAS methods (EPA, 1991c). The matrix interferences encountered in analysis of metals in tissue may require case-specific techniques for overcoming interference problems. If tributyltin analysis is being performed, the methods of Rice et al. (1987) or Uhler et al. (1989) should be consulted.

10.0 GUIDANCE FOR PERFORMING TIER II EVALUATIONS

10.1 Tier II: Water Column Effects

If a water column determination cannot be made in Tier I, the Tier II water column evaluation must be conducted for comparison with numeric water-quality standards (WQS) (Section 5.1). There are two approaches for the Tier II water column evaluation for WQS compliance. One approach is to use numerical models provided in Appendix C of this manual as a screen, assuming conservatively that all of the contaminants in the dredged material are released into the water column during the disposal process. The other approach applies the same model, using the results from a chemical analysis of an elutriate prepared from the dredged material (Section 10.1.2.1).

10.1.1 Screen Relative To WQS

A screening approach may reduce the evaluation effort for dredged material that will cause only minimal water column impact. In a typical disposal operation, most contaminants remain associated with the dredged material that settles to the bottom and cause limited water column impact during descent. The screen is not a requirement but is intended to reduce the effort required to develop information required for factual determinations.

Appendix C provides guidance on which numerical computer or analytical models should be applied to particular dredged material disposal projects and the information that is necessary to perform the evaluations. Versions of models for use on IBM-compatible microcomputers and example applications are provided on the diskettes in the pocket inside the back cover of this manual. The output of the appropriate model is used to determine if additional testing is needed.

The model need be run only for the contaminant of concern that requires the greatest dilution. If this contaminant is shown to meet the WQS, all of the other contaminants that require less dilution will also meet the WQS. The contaminant requiring the greatest dilution is determined by calculating the dilution that would be required to meet the WQS. To determine the dilution *D,* the following equation is solved for each contaminant of concern in terms of dissolved concentrations:

$$D = [(C_s \times SS/1000) - C_{wq}] / (C_{wq} - C_{ds})$$

where C_s = concentration of the contaminant in the dredged material expressed as micrograms per kilogram (μg/Kg), on a dry weight basis;

SS	=	suspended solids concentration in the dredged material discharge expressed as grams per liter (g/L);
1000	=	conversion factor, g to Kg;
C_{wq}	=	WQS in micrograms per liter (µg/L); and
C_{ds}	=	background concentration of the contaminant at the disposal site in micrograms per liter (µg/L).

Note that if the concentration of the constituent in the dredged material (C_s x SS/1000) is less than C_{wq}, no calculation is necessary since no dilution is required. Note also that, if the ambient disposal-site water concentration (C_{ds}) of a constituent is greater than C_{wq}, water quality at the disposal site cannot be met by dilution. Appendix C provides detailed information for performing the above calculations and identifying the contaminant of concern requiring the greatest dilution.

The concentration of this contaminant is then modeled to determine its maximum concentration in the water column outside the boundary of the mixing zone. If this concentration is below the applicable WQS, no additional testing is necessary to make a determination regarding WQS. If the concentration is higher, additional testing is necessary, as described in Section 10.1.2.

Note that the procedure described above cannot be used to evaluate water column impact. It can be used *only* to determine whether additional testing for potential water-column impact, as described in Section 10.1.2, is necessary.

10.1.2 Elutriate Analysis Relative To WQS

For an elutriate analysis, the numerical mixing model (Appendix C) is run with chemical data obtained from an elutriate test conducted on the dredged material. The standard elutriate analysis is described in Section 10.1.2.1 and the analytical procedures for measuring constituents in the water are provided in Section 9.4.2. The model is, in effect, using data that more accurately represent the contaminant concentrations that will be present in the water column after consideration of mixing. If the numerical model (Appendix C) predicts that the concentration of all contaminants of concern at the edge of the mixing zone is less than the available, applicable WQS, the dredged material complies with WQS. Otherwise, it does not.

10.1.2.1 Standard Elutriate Preparation

The standard elutriate test is used to predict the release of contaminants to the water column resulting from open water disposal. Prior to use, all labware should be thoroughly cleaned as appropriate for the contaminant analysis. At a minimum, labware should be washed with detergent, rinsed with acetone, five times with tap water, placed in a clean 10% HCl acid bath for a minimum of 4 h, rinsed five times with tap water, and then thoroughly flushed with either distilled or deionized water.

The elutriate should be prepared by using water from the dredging site. Enough elutriate should be prepared for the chemical analyses and for the water column toxicity tests in Tier III.

The elutriate is prepared by subsampling approximately 1 L of the dredged material from the well-mixed original sample. The dredged material and unfiltered water are then combined in a sediment-to-water ratio of 1:4 on a volume basis at room temperature (22 ± 2°C). This is best accomplished by volumetric displacement. After the correct ratio is achieved, the mixture is stirred vigorously for 30 min with a mechanical or magnetic stirrer. At 10 min intervals, the mixture is also stirred manually to ensure complete mixing. After the 30 min mixing period, the mixture is allowed to settle for 1 h. The supernatant is then siphoned off without disturbing the settled material, and centrifuged to remove particulates prior to chemical analysis (approximately 2,000 rpm for 30 min, until visually clear). If the elutriate is to be used for toxicity testing, refer to the procedures in Section 11.1.4.

10.1.2.2 Chemical Analysis

Analytical procedures for specific constituents in water are provided in Section 9.4.2.

10.1.2.3 Comparison with WQS (Standard Elutriate Test)

The model need be run only for the contaminant that requires the greatest dilution to make a WQS determination. This contaminant may or may not be the same as that run in the screen (Section 10.1.1). Calculations must therefore be conducted for all of the contaminants detected during analysis of the elutriate to determine which one requires the greatest dilution. The contaminant requiring the greatest dilution is determined by calculating the dilution that would be required to meet the WQS. To determine the dilution D, the following equation is solved for each contaminant of concern in terms of dissolved concentrations:

$$D = (C_e - C_{wq})/(C_{wq} - C_{ds})$$

C_e = concentration of the dissolved contaminant in the standard elutriate in micrograms per liter (µg/L). All other terms are as previously defined in Section 10.1.1.

10.2 Theoretical Bioaccumulation Potential (TBP) of Nonpolar Organic Chemicals

The TBP is an approximation of the equilibrium concentration in tissues if the dredged material in question were the only source of contaminant to the organisms. The TBP calculation in Tier II is applied as a coarse screen to predict the magnitude of bioaccumulation likely to be associated with nonpolar organic contaminants in the dredged material. At present the TBP calculation can be performed only for nonpolar organic chemicals such as PCBs. However, methods for TBP calculations with metals and polar organic compounds are under development and may be added to this manual in the future. For the present, bioaccumulation potential of polar organic compounds, organometals, and metals in dredged material can only be tested (in Tiers III or IV), not calculated. However, it is still useful to calculate the TBP, which provides an indication of the magnitude of bioaccumulation of nonpolar organic compounds that may be encountered in testing at higher tiers. Additionally, if the TBP of the nonpolar organic compounds indicates that these contaminants are not bioavailable, this calculation may eliminate the need for further evaluation of these compounds and thereby reduce efforts in higher tiers.

Nonpolar organic chemicals include all organic compounds that do not dissociate or form ions. This includes the chlorinated hydrocarbon pesticides, many other halogenated hydrocarbons, PCBs, many PAHs including all the priority pollutant PAHs, dioxins and furans. It does not include metals and metal compounds, organic acids or salts, or organometallic complexes such as tributyltin or methyl mercury.

The environmental distribution of nonpolar organic chemicals is controlled largely by their solubility in various media. Therefore, in sediments they tend to occur primarily in association with organic matter (Karickhoff, 1981). In organisms they are found primarily in the body fats or lipids (Konemann and van Leeuwen, 1980; Geyer et al., 1982; Mackay, 1982; Bierman, 1990). Bioaccumulation of nonpolar organic compounds from dredged material can be estimated from the organic carbon content of the material, the lipid content of the organism, and the relative affinities of the chemical for sediment organic carbon and animal lipid content.

The TBP calculation assumes that various lipids in different organisms and organic carbon in different sediments are similar and have similar distributional properties. Other simplifying assumptions are that chemicals are freely exchanged between the sediments and tissues and that compounds behave

conservatively. In reality, compound size and structure may influence accumulation, and portions of organic compounds present on suspended particulates may have kinetic or structural barriers to availability. Another important assumption implicit in the TBP calculations is that there is no metabolic degradation or biotransformation of the chemical. Organic-carbon normalized contaminant concentrations are used such that the sediment-associated chemical can be characterized as totally bioavailable to the organism. Calculations based on these assumptions yield an environmentally conservative TBP value for the dredged material if the dredged material in question is the only source of the contaminant for the organism. However, note that TBP calculations are not valid for sediments with TOC $\leq$ 0.2%.

It is possible to relate the concentration of a chemical in one phase of a two-phase system to the concentration in the second phase when the system is in equilibrium. The TBP calculation focuses on the equilibrium distribution of a chemical between the dredged material or reference sediment and the organism. By normalizing nonpolar organic chemical concentration data for lipid content in organisms, and organic carbon in dredged material or reference sediment, it is possible to estimate the preference of a chemical for either phase. This approach is based on the work of Konemann and van Leeuwen (1980) and Karickhoff (1981).

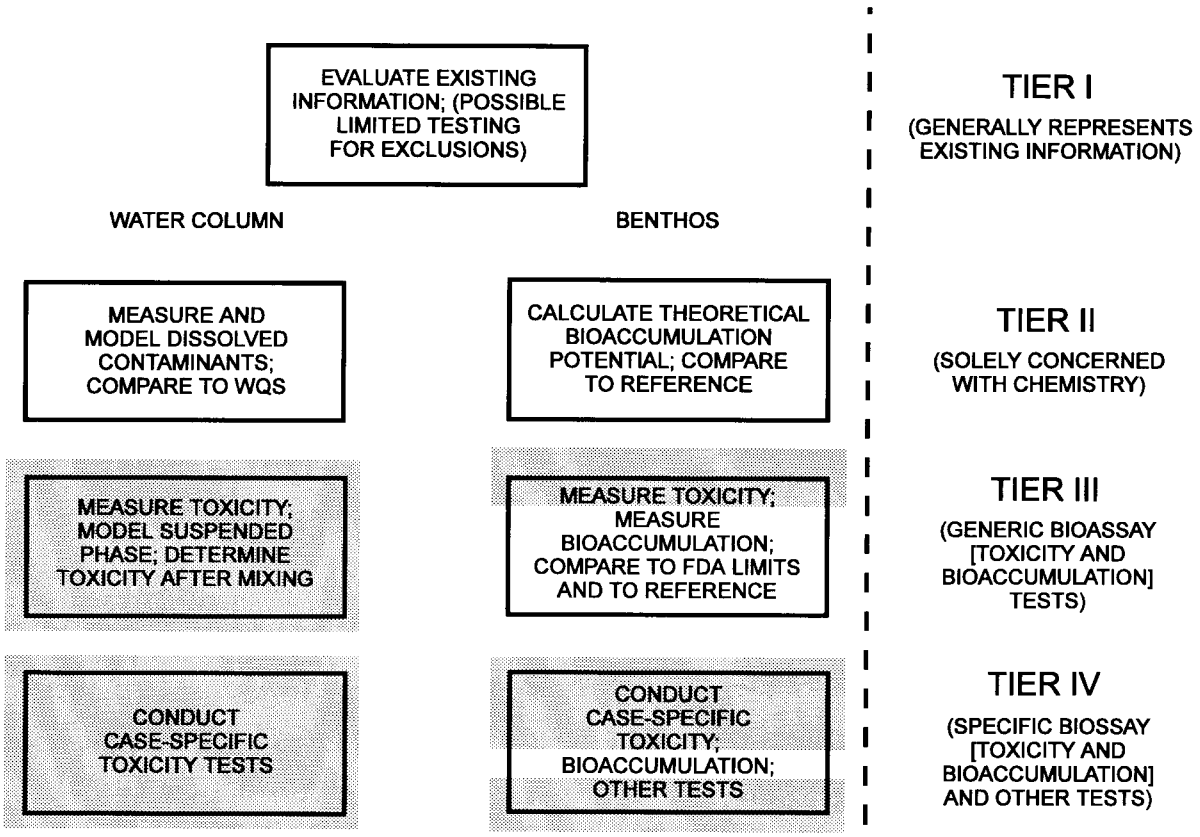
McFarland (1984) took the approach one step farther. He calculated that the equilibrium concentration of nonpolar organic chemicals, which the lipids of an organism could accumulate as a result of exposure to dredged material, would be about 1.7 times the organic carbon-normalized concentration of the chemical in the dredged material. Concentrations are directly proportional to the lipid content of the organism and the contaminant content of the dredged material or reference sediment, and are inversely proportional to the organic carbon content of the dredged or reference material (Lake et al., 1987).

The possible chemical concentration in an organism's lipids [the lipid bioaccumulation potential (LBP)] would theoretically be 1.7 times the concentration of that chemical in the sediment organic carbon. Rubinstein et al. (1987) have shown, based on field studies with PCBs, that a value of 4 for calculating LBP is appropriate. However, note that more precise values for specific chemicals are now available. Current information on such values may be obtained from the ACOE Contaminated Sediment Bulletin Board (BBS: phone number is 601-634-4380; settings are N, 8, 1). LBP represents the potential contaminant concentration in lipid if the sediment is the only source of that contaminant to the organism. It is generally desirable to convert LBP to whole-body bioaccumulation potential for a particular organism of interest. This is done by multiplying LBP by that organism's lipid content, as determined by lipid analysis or from reported data. Soft-bodied invertebrate lipid contents may range from 1 - 2% wet weight (based on data from an oligochaete, midge, and amphipod species [G. Ankley, EPA Duluth and H. Lee, EPA Newport, pers. comm.]).

Theoretical bioaccumulation potential (TBP) can be calculated relative to the biota sediment accumulation factor (BSAF) as

$$TBP = BSAF\ (C_s / \%TOC)\ \%L$$

where TBP is expressed on a whole-body wet-weight basis in the same units of concentration as C_s, and



C_s = concentration of nonpolar organic chemical in the dredged material or reference sediment (any units of concentration may be used);

BSAF = 4 (Ankley et al., 1992c)

%TOC = total organic carbon content of the dredged material or reference sediment expressed as a decimal fraction (i.e., 2% = 0.02); and

%L = organism lipid content expressed as a decimal fraction (i.e., 3% = 0.03) of whole-body wet weight.

This calculation is based on work by McFarland and Clarke (1987).

11.0 GUIDANCE FOR PERFORMING BIOLOGICAL EFFECTS TESTS

Biological effects tests, i.e., toxicity tests, may be necessary if Tier I evaluations conclude that the dredged material contains contaminants which might result in an unacceptable adverse impact to the benthic environment and/or the water column. Toxicity tests with whole sediment are used to determine the potential for effects on benthic (bottom dwelling) organisms; toxicity tests with suspensions/solutions of dredged material are conducted to determine the potential effects on water column organisms.

The objective of water column toxicity tests is to determine the potential impact of dissolved and suspended contaminants on organisms in the water column, after considering mixing. Test organisms should be representative of appropriately sensitive water column species existing in the vicinity of the disposal site.

The objective of benthic toxicity tests is to determine the potential impact of whole sediment on benthic organisms at and beyond the boundaries of the disposal site. The organisms used in testing should be representative of appropriately sensitive infaunal or epifaunal organisms existing in the vicinity of the disposal site. Benthic toxicity tests are intended to determine the potential chemical toxicity of a dredged material as distinct from its physical (e.g., grain-size) effects. Some organisms, particularly marine, are affected by differences in sediment textures or absence of sediments (McFarland, 1981; DeWitt et al., 1988). Control and reference sediments should be selected to minimize any artifactual effects of differences in grain size. If the sediment texture varies considerably between the dredged material and the control or reference sediments, any possible effects of grain size have to be determined and considered when designing the tests and evaluating the test results (e.g., DeWitt et al., 1988).

11.1 Tier III: Water Column Toxicity Tests

Tests to evaluate dredged-material impact on the water column involve exposing test organisms to an elutriate dilution series containing both dissolved and suspended components of the dredged material. The test organisms are added to the exposure chambers and exposed for a prescribed period (usually 96 h though some tests, e.g., bivalve larvae, may be run for shorter periods). The surviving organisms are examined at specified intervals and/or at the end of the test to determine if the test material is producing an effect. An introductory guide to general toxicity testing is presented in Part 8000 of APHA (1989) and in ASTM (1994b). Biological testing aspects of these reference publications may be followed as long as they do not conflict with this manual.

11.1.1 Species Selection

Three species are recommended for use in the water column exposure and should represent different phyla where possible (Table 11-1). The rationale for testing more than a single species is to cover the potential range of differing species sensitivities and to be environmentally protective. Of the species tested, at least one needs to be a sensitive benchmark (starred) species except as provided below; however, this does not preclude the use of more than one benchmark species. Those non-benchmark species listed in Table 11-1 or other species can be used if a summary of test conditions and test acceptability criteria similar to the starred benchmark species are established, and data from reference toxicity tests (see Appendix G.2.10.5.2) are provided on the sensitivity of the species. In order to be technically justfied, species proposed for use regionally and not listed in Table 11-1 would need to meet the species characteristics criteria, provided later in this Section, and proponents need to generate the following supporting information:

- data from toxicity tests using a set of reference chemicals with differing modes of action demonstrating that the proposed species is as sensitive or more sensitive than the species in Table 11-1

- summary of test conditions and test acceptability criteria.

If species proposed for use regionally are tested in conjunction with a benchmark species, the above supporting information is desirable but not needed. However, if the region substututes all species, the above information is needed.

The test organisms may be from healthy laboratory cultures or may be field collected, but not from within the influence of former or active disposal sites or other discharges. Ideally, the test species should be the same or closely related to those species that naturally dominate biological assemblages in the vicinity of the disposal site. Species characteristics to consider when designing water-column tests include, not in order of importance:

- readily available year-round
- tolerate handling and laboratory conditions
- give consistent, reproducible response to toxicants
- related phylogenetically and/or by ecological requirements to species characteristic of the water column of the disposal site area in the season of the proposed disposal
- standardized test protocols are available
- can be readily tested as juveniles or larvae to increase sensitivity
- important ecologically, economically, and/or recreationally
- appropriately sensitive.

Table 11-1. Candidate Toxicity Test Species for Determining Potential Water Column Impact of Dredged Material Disposal. Details of testing procedures are provided in Appendix E.

Crustaceans

Mysid shrimp, *Mysidopsis* sp.* (N)[d]
*Neomysis americana** (N)
*Holmesimysis costata** (N)
Grass shrimp, *Palaemonetes* sp. (N)
Commercial shrimp, *Penaeus* sp. (N)
Cladocerans, *Daphnia magna** (F) [d]
*Daphnia pulex** (F) [d]
*Ceriodaphnia dubia** (F)[d]

Fish

Silversides, *Menidia* sp.* (N) (E)[d]
Sheepshead minnow,
*Cyprinodon variegatus** (N)[d]
Speckled sanddab, *Citharicthys stigmaeus* (N)
Grunion, *Leuresthes tenuis* (N)
Fathead minnow, *Pimephales promelas** (F)[d]
Bluegill sunfish, *Lepomis macrochirus* (F)
Channel catfish, *Ictalurus punctatus* (F)
Rainbow trout, *Oncorhynchus mykiss** (F)

Bivalves

Larvae of
Oyster, *Crassostrea* sp.* (N,E)[a]
Mussel, *Mytilus edulis** (N,E)[a]

Echinoderms

Larvae of
Sea urchins, *Strongylocentrotus* sp.*[bc] (N)
Lytechinus pictus[b] (N)
Sanddollar, *Dendraster* sp.*[bc] (N)

Note: Examples are not presented in order of importance; however, the asterisks indicate sensitive recommended benchmark species. Benchmark species comprise a substantial data base, represent the sensitive range of a variety of ecosystems, and provide comparative data on the relative sensitivity of local test species. Other species may be designated in future as benchmark species by EPA and USACE when the data on their response to contaminants are adequate.

[a] fertilized egg to hinged, D-shaped prodissoconch I larvae. Note that these two species can be used in estuarine waters down to appropriate low levels of salinity (see Appendix E).

[b] fertilized egg to pluteus larvae

[c] sperm fertilization

[d] These species can also be used in sublethal, chronic testing (methods for such testing are available but not detailed in this manual).

For the purpose of this manual, related to the tolerances of the test animals, (F) = Freshwater, salinity ≤ 1 ‰ (N) = Near Coastal, salinity ≥ 25‰ (E) = Estuarine, salinity 1-25‰. It is recognized that the commonly accepted salinity range for estuaries is 1-35‰ and near coastal salinity is usually greater than 30‰ salinity.

In addition to species occurring at the disposal site, other representative commercially available species or sensitive life stages of economically important species may be used. Mysids of the genera *Mysidopsis, Neomysis,* or *Holmesimysis* are highly recommended as test species. Embryo-larval stages of echinoderms, crustaceans, molluscs, or fish are also appropriate organisms. Adult fish and molluscs and large crustaceans must not be used for water column toxicity testing because of their generally greater resistance to contaminants, except as additional test organisms where data on economically important species are necessary to address public or regional concerns.

Regardless of their source, test organisms should be collected and handled as gently as possible. They should be gradually acclimated to the test conditions if test conditions differ from holding conditions. Field collected organisms must be tested within 2 weeks of collection. Animals from established laboratory cultures can be held indefinitely. Further details on methods are provided in ASTM (1994b).

11.1.2 Apparatus

Water column toxicity tests are generally conducted as static exposures in pre-cleaned glass chambers equipped with covers to minimize evaporation. The size of the chambers depends on the size of the test species. Before use, all glassware should be washed with detergent, rinsed five times with tap water, placed in a clean 10% HCl acid bath for a minimum of 4 h, rinsed with acetone, five times with tap water, and then thoroughly flushed with either distilled or deionized water.

Equipment and facilities must provide acceptable lighting requirements and temperature control. An environmental incubator or a water-bath system that allows temperature control within ±1°C is recommended.

11.1.3 Laboratory Conditions

Water column toxicity tests should be conducted under conditions known to be non-stressful to the test organisms. Salinity for marine/estuarine organisms should be stable within ±2‰ and, for all organisms, temperature should be stable within ±2°C throughout the exposure period. Dissolved-oxygen concentration should not be allowed to fall below an absolute minimum of 40% saturation for warm water species and 60% for cold water species. The temperature, salinity (if appropriate), dissolved oxygen, and pH in the test containers should be measured and recorded daily. Measurements of other parameters, for instance ammonia, may also be useful but need not be done daily.

11.1.4 Laboratory Procedures

Elutriate Preparation

Elutriate should be prepared using water collected from the dredging site. Disposal site water, clean seawater or freshwater, or artificial sea/salt mixtures should be used as dilution water for the tests. If sea/salt mixtures are used, they must be prepared in strict accordance with the manufacturer's instructions and allowed to age (with aeration) to ensure that all salts are in solution and pH has stabilized before use in any test. The elutriate is prepared by subsampling approximately 1 L of the homogenized dredged-material sample. The dredged material and unfiltered dredging site water are then combined in a sediment-to-water volumetric ratio of 1:4 at room temperature (22 ± 2°C). The mixture is then stirred vigorously for 30 min with a mechanical or magnetic stirrer. At 10 min intervals, the mixture is also stirred manually to ensure complete mixing. After the 30 min mixing period, the mixture is allowed to settle for 1 h. The liquid plus the material remaining in suspension after the settling period represents the 100% liquid plus suspended particulate phase. The supernatant is then carefully siphoned off, without disturbing the settled material, and immediately used for testing. With some very fine-grained dredged materials, it may be necessary to centrifuge the supernatant until the suspension is clear enough for the organisms to be visible in the testing chamber. Note that 15-40 L of elutriate may need to be prepared to test some species.

Test Design

The number of replicate exposure chambers per treatment should be determined according to the guidance in Appendix E. A minimum of five replicates per treatment and 10 organisms (except zooplankton or larvae) per replicate is generally recommended. Organism loading density must be low enough to avoid overcrowding stress.

At least three concentrations of the dredged-material elutriate should be tested; recommended treatments are 100%, 50%, and 10%. Water from the same source in which the animals were held prior to testing must be included as a control treatment subject to test survival acceptability criteria for controls (Appendix G). To properly evaluate the test results, any toxicity at 100% dilution water should also be determined.

The test organisms should be approximately of equal size and/or age and assigned randomly to the different treatments. Zooplankton and larvae are usually transferred with the aid of a pipette. Air must not be trapped on or under the animals during the transfer process. Larger animals may be transferred in fine-mesh nets. Animals which are dropped or exhibit abnormal behavior should be discarded.

The test chambers should be covered and randomly placed in an incubator or water bath. The test type is static non-renewal; the control and test solutions are not replaced. During the exposure period, aeration should not be supplied (unless necessary to keep dissolved oxygen concentration above 40% saturation

for warm water species or 60% for cold water species), and the test solutions should not be stirred. Some species of crustaceans, particularly larval forms, may require feeding during the test. All food used must be analyzed to ensure that it is acceptably free of contaminants and will support survival, growth or reproduction of test organisms (cf. EPA, 1994b).

Recommended test duration is 48-96 h for zooplankton and some larvae (e.g., oysters) and up to 96 h for other organisms. For bivalve larvae, the ASTM (1994c) procedure should be used. Useful procedures for other organisms are given in ASTM (1994b). For some tests, intermediate time observations may be made of survival but, for other tests, survival is only assessed at the end of the testing period. For intermediate observations, care must be taken to minimize any stress to the test organisms. Only the number of living organisms are counted, not the number of dead. An animal is judged dead if it does not move either after the water is gently swirled or after a sensitive part of its body is gently touched with a probe. At intermediate observations, a pipette or forceps is used to remove dead organisms, molted exoskeletons, and food debris.

If greater than acceptable mean mortality or abnormal development occurs in the control as defined in the procedures for proper conduct of that test, the test must be repeated. Further QA/QC considerations are provided in Appendix G.

11.1.5 Data Presentation and Analysis

Data Presentation

The data for each test species should be presented in separate tables that include the following information:

- the scientific name of the test species
- the number of organisms in each treatment at the start of the test
- the number of organisms alive at each observation period, if applicable
- the number of organisms recovered alive and/or in normal health from each chamber at the end of the test
- additional information including water quality and any behavioral or other abnormalities.

Data Analysis

It is possible that no mortality or other effects will be observed in any of the treatments or that survival or other effects in the dredged material treatments will be equal to or higher than in the control or in the dilution water treatments. In either of these situations, there is no need for statistical analysis and no indication of water column toxicity attributable to the dredged material. However, if survival or other

effects in the dilution water treatment is at least 10% greater than the 100% dredged-material treatment, the data have to be evaluated statistically to determine whether the dredged-material suspension is significantly more toxic than the dilution water. If the 100% dredged-material treatment is not statistically different from the dilution water, the dredged material is predicted not to be acutely toxic to water column organisms. An LC_{50} should not be calculated unless at least 50% of the test organisms die in at least one of the serial dilutions . If there are no mortalities greater than 50%, then the LC_{50} is assumed to be ≥100%. If a statistical difference exists and greater than 50% mortality or other effects occur in all of the treatments, it is not possible to calculate an LC_{50} or EC_{50} value. If the conditions are highly toxic, such that the 10% treatment has greater than 50% mortality, further dilution must be made (new treatments of less than 10% dredged material) to attain a survival of greater than 50% and determine the LC_{50} or EC_{50} by interpolation. Statistical procedures recommended for analyzing the test data are described in detail in Appendix D.

11.1.6 Conclusions

The Tier III water-column effects evaluation involves using a numerical model comparison with the WQS. Descriptions of the models and applications are given in Appendix C, and the models are provided on the diskettes that can be found in the pocket inside the back cover of this manual.

The modeled concentrations of the dredged material (expressed as percentages) are compared to 0.01 of the 48- or 96-h LC_{50} or EC_{50}, depending on the test duration. The maximum allowable concentration outside the mixing zone is 0.01 LC_{50} or EC_{50}. Note that the 0.01 factor is intended for acute mortality data (e.g., relating acute to chronic toxicity) and not for more subtle effects such as abnormalities, growth or reproduction, including EC_{50} data (NAS, 1972). However, in the absence of other alternatives, the 0.01 application factor should be applied to EC_{50} data although it is recognized that these results will be conservative and that derivation of this historic application factor was largely a matter of "best professional judgement" by the NAS (1972). Thus, site-specific review may be required in some cases to determine compliance.

11.2 Tier III: Benthic Toxicity Tests

Toxicity tests with whole sediment are designed to determine whether the dredged material is likely to produce unacceptable adverse effects on benthic organisms. In benthic toxicity tests, the test animals are exposed to the whole sediment and any effects recorded.

11.2.1 Species Selection

Species representing three life history strategies are recommended for use in the whole sediment toxicity tests, one each representing a filter feeder, deposit feeder and a burrowing organism where possible (Table 11-2). The rationale for testing more than a single species is to cover the range of differing species sensitivities and to be environmentally protective. No single species is adequately protective of the broad range of possible chemical contaminants nor of the equally broad range of possible biological responses. Of the species tested, at least one sensitive benchmark (starred) species needs to be be used in all cases except as provided below; however, this does not preclude the use of benchmark species representative of all three required categories. If only two different species are being tested they should, together, cover the following three life history strategies: filter feeder, deposit feeder, burrower. Since amphipods are excellent organisms for short term toxicity, they are recommended as one of the species to be tested. Non-benchmark species listed in Table 11-2 can be used if a summary of test conditions and test acceptability criteria similar to the starred benchmark species are established and data from reference toxicity tests (see Appendix G.2.10.5.2) are provided on the sensitivity of the species. In order be technically justified, species proposed for use regionally and not listed in Table 11-2 need to meet the species characteristics criteria provided later in this section and proponents need to provide the following supporting information:

- data from toxicity tests using a set of reference chemicals with differing modes of action demonstrating that the proposed species is as sensitive or more sensitive than the species in Table 11-2

- summary of test conditions and test acceptability criteria.

If species proposed for use regionally are tested in conjunction with a benchmark species, the above supporting information is desirable but not required. However, if the region substitutes all species, the above information is needed.

Benthic organisms are used to evaluate the potential benthic impact of dredged material disposal. Testing of contaminated sediments (e.g., Word et al., 1989; Gentile et al., 1988; Rogerson et al., 1985) and regulatory program experience since 1977 under the Marine Protection, Research, and Sanctuaries Act and the Clean Water Act have shown that different species have various degrees of sensitivity to the physical and chemical composition of sediments.

To accurately evaluate potential benthic impact, appropriately sensitive toxicity test species should be related as closely as possible, both phylogenetically and ecologically, to benthic organisms in the disposal

Table 11-2. Candidate Acute Toxicity Test Species for Determining Potential Benthic Impact of Dredged-Material Disposal. Details of testing procedures are provided in Appendix E. Additional guidance is provided in ASTM (1994d,e,f,g) and EPA (1994c,d).

Amphipod Crustaceans

*Ampelisca abdita** (N)[a] [d,b]
*Rhepoxynius abronius** (N) [d,b]
Grandidierella japonica (N) [d,b]
Corophium sp. (N) [f,d,b]
*Leptocheirus plumulosus** (E,N)[a] [d,b]
*Eohaustorius estuarius** (E) [d,b]
*Hyalella azteca** (E,F)[a] [d,b]

Polychaetes

Neanthes arenaceodentata (N)[a] [d,b]

Juvenile Bivalves (clams)

Paper pondshell freshwater mussel, *Anodonta imbecillis* (F) [f,b]

Crustaceans other than Amphipods

Mysid shrimp, *Mysidopsis* sp. (N) [f,d]
Neomysis americana (N) [f]
Holmesimysis costata (N) [f]
Commercial shrimp, *Penaeus* sp. (N) [d,b]
Grass shrimp, *Palaemonetes* sp. (N,E)[b] [d]

Insect Larvae

Midges, *Chironomus tentans** (F)[a] [d,b]
*C. riparius** (F)[a] [d,b]
Mayfly, *Hexagenia limbata* (F) [d,b]

Oligochaetes

Pristina leidyi (F) [d,b]
Tubifex tubifex (F)[a] [d,b]
Lumbriculus variegatus (F)[a] [d,b]

Note: Examples are not presented in order of importance; however, the asterisks indicate sensitive recommended benchmark species. Benchmark species comprise a substantial data base, represent the sensitive range of a variety of ecosystems, and provide comparative data on the relative sensitivity of local test species. Other species may be designated in future as benchmark species by EPA and the USACE when the data on their response to contaminants are adequate. Only benthic species should be tested. Although sediment dwellers are preferable, intimate contact with sediment is acceptable. Note that testing with all recommended taxa is not required; however, at least one starred amphipod taxon must be tested.

[f = filter feeder; d = deposit feeder; b = burrower]. Note that *A. abdita*, *L. plumulosus*, *C. tentans*, and *H. limbata* are not direct filter feeders, but are suspension feeders.

[a] These species can also be used in sublethal, chronic testing (methods for such testing are available but not detailed in this manual).

[b] This species can be used in estuarine waters down to appropriate low levels of salinity (see Appendix E).

For the purposes of this manual, related to the tolerances of the test animals, (F) = Freshwater, salinity $\leq$ 1‰ (N) = Near Coastal, salinity $\geq$ 25‰ (E) = Estuarine, salinity 1-25‰. It is recognized that the commonly accepted salinity range for estuaries is 1-35‰ and near coastal water is usually greater than 30‰ salinity.

site area. Commercially important but possibly less sensitive benthic species in the vicinity of the disposal site may also be considered for testing.

Sediment grain size is likely to vary substantially between the dredged material, the reference sediment, and the control sediment. If candidate test species are overly sensitive to the different grain sizes (for instance, excessive mortality in the reference sediments attributable to grain size and not to other factors), either this must be taken into account (e.g., DeWitt et al., 1988) or other, more grain-size tolerant species should be considered for the project.

Final selection of test species for a particular dredged material disposal project should be made in consultation with regional regulatory and scientific personnel. Two phylogenetically and ecologically different species are recommended to account for different sensitivities to contaminants. The following is a list, not necessarily in order of importance, of characteristics to consider for species selection:

- readily available year-round
- preferably ingest sediments
- tolerate grain sizes of dredged material and control and reference sediments equally well or differences should be accounted for
- give consistent, reproducible response to toxicants
- tolerate handling and laboratory conditions
- related phylogenetically and/or by ecological requirements to species characteristic of the benthic environment of the disposal site area in the season of the proposed disposal
- standardized test protocols are available
- important ecologically, economically, and/or recreationally
- appropriately sensitive.

Infaunal amphipods are excellent organisms for short term toxicity tests with whole sediment (Swartz et al., 1979, 1985; Mearns and Word, 1982; Rogerson et al., 1985; Nebeker et al., 1984; Gentile et al., 1988; Scott and Redmond, 1989; Word et al., 1989; Burton, 1991), and are strongly recommended as appropriate test species for acute toxicity bioassays in marine/estuarine/fresh waters. Guidance on available testing procedures (static, 10-d exposures) provided in ASTM (1994d,e) may be followed on all points that do not conflict with this manual. Infaunal amphipods are:

- sensitive
- readily available
- as a group, tolerant of a wide range of grain sizes and laboratory exposure conditions
- ecologically relevant to most dredged material disposal sites.

The identity of all species should be verified by experienced taxonomists, particularly for animals collected in the field. If the toxicity test animals are also to be used in estimating bioaccumulation potential, the factors discussed in Section 12.1.1 for species selection should also be considered.

11.2.2 Laboratory Procedures

General Test Procedures

Acceptable water quality parameters during testing include but are not necessarily restricted to:

- the correct temperature and pH range
- adequate oxygen levels
- proper lighting
- the correct salinity range (near coastal and estuarine organisms)
- the correct hardness range (fresh water organisms)
- the absence of, or insignificant concentrations of, toxicants such as ammonia.

Amphipod and other small organism tests are often, but not always, conducted in 1 L containers under static conditions (Appendix E). Static renewal or even flow-through methods such as those described by Redmond et al. (1989) or Benoit et al. (1993) may be required for certain tests or where static non-renewal conditions would result in unacceptable build-up of, for instance, ammonia and/or sulfides (see second and third paragraphs, Ammonia and Sulfide toxicity, this section).

Before use, all glassware should be washed with detergent, rinsed with acetone, five times with tap water, placed in a clean 10% HCl acid bath for a minimum of 4 h, rinsed five times with tap water, and then thoroughly flushed with either distilled or deionized water. Equipment and facilities must provide acceptable lighting requirements and temperature control. An environmental incubator or a water-bath system that allows temperature control within ± 1°C is recommended.

Dilution water should not be stressful to the test organisms, and should be stable throughout the exposure period. Salinity for marine/estuarine organisms should be stable within ± 2‰ and, for all organisms, temperature should be stable within ± 2°C throughout the exposure period. Dissolved oxygen concentration should not be allowed to fall below an absolute minimum of 40% saturation for warm water species and 60% for cold water species. The flow to the exposure chamber should be directed to achieve good mixing without disturbing the sediment on the bottom of the chamber.

A minimum of five replicate exposure chambers for the dredged material, reference, and control is recommended. The standard test duration is 10 d.

The quantity of sediment needed depends on the size of the exposure chambers. The sediment should be deep enough to meet the biological needs of the test organisms, i.e., allow organisms to burrow in their normal position, etc. Overcrowding of organisms must be avoided.

Prior to use in toxicity tests, sediments must be thoroughly homogenized. Very small amounts of clean diluent water may be added to facilitate mixing. If separation into liquid and solid phases occurs in posthomogenization storage, remixing will be required prior to usage.

The reference and control sediments, as well as the dredged material being tested, may contain live organisms. If necessary, macrobenthic organisms can be removed by press-sieving the sediments through an appropriately sized screen immediately prior to testing. The material remaining on the screen should be noted and discarded.

The experimental procedure described in ASTM (1994d) should be followed for preparing the exposure chambers for amphipod toxicity tests. For larger exposure chambers, sediment should be placed on the bottom of the exposure chamber and covered with clean diluent water; any sediment suspended during placement should be allowed to settle for 24 h before introducing the test organisms. In continuous-flow tests, the flow should be established after most of the suspended sediment has settled, usually 12 to 24 h, but at least 1 h before introducing the test organisms.

During the exposure period, daily records should be kept of obvious mortalities, emergence of infaunal organisms, formation of tubes or burrows, and any other or unusual behavior. Daily records of water quality (e.g., dissolved oxygen, salinity (if appropriate), ammonia, temperature, pH) should be maintained using test containers appropriate for this purpose. In flow-through or static-renewal systems, water quality may be kept within acceptable bounds by increasing the flow rate or frequency of water changes.

After the exposure period, live organisms are removed to clean diluent water, which may include sieving the sediments, and then counted. If greater than acceptable mean mortality occurs in the control, as defined in the procedures for proper conduct of that test, the test must be repeated. Organisms which show any response to gentle probing of sensitive parts or gentle swirling of the water should be considered alive. Sediment dwellers (e.g., amphipods) not recovered at the end of the test have to be considered dead. If organisms from these toxicity tests are to be used in estimating bioaccumulation potential, the survivors are gently and rapidly counted and then treated as described in Section 12.

Ammonia and Sulfide Toxicity

Whether ammonia is or is not a contaminant of concern depends on the disposal site. In order to identify elutriate or solid phase dredged material toxicity due to ammonia, it is essential to make routine measurements of ammonia on appropriate test fractions. These measurements are compared to water-only toxicity data for the same species used in the dredged material test (see Appendix F). The water-only toxicity data generated separately should be generated under conditions (e.g., pH, test length) reasonably similar to those in the test with the dredged material. If ammonia concentrations are too low to have potentially caused the observed toxicity in the dredged material sample, other contaminants are responsible for the toxicity. If ammonia concentrations are high enough to have caused the observed toxicity, toxicity identification evaluation (TIE) procedures should be used to confirm this suspicion. When there is no TIE confirmation that ammonia is responsible for sediment toxicity, it must be assumed that persistent contaminants other than ammonia are causing toxicity. Full details of procedures to identify ammonia as a toxicant in toxicity tests with dredged material are provided in Appendix F.

Whenever chemical evidence of ammonia is present at toxicologically important levels, i.e. ammonia concentrations exceed the species-specific acceptability ranges shown below (or 20 mg/L for freshwater organisms), and ammonia is not a contaminant of concern at the disposal site, the laboratory analyst should set up one or more beakers explicitly for the purpose of measuring interstitial ammonia. Ammonia in the sediment interstitial water should be reduced to below the species-specific level shown below (or to below 20 mg/L for freshwater organisms) before adding the benthic test organisms. Ammonia concentrations in the interstitial water can be reduced by sufficiently aerating the sample at saturation and replacing two volumes of water per day. The analyst should measure interstitial ammonia each day until it reaches a concentration below the appropriate species-specific level (or ≤20 mg/L for freshwater organisms). After placing the test organisms in the sediment, the analyst should ensure that ammonia concentrations remain within an acceptable range by conducting the toxicity test with continuous flow or volume replacement not to exceed two volumes per day. Peer-reviewed papers that deal with ammonia in sediments include: Dewitt et al. (1988), Scott and Redmond (1989), Burton (1991), EPA (1992, 1994c, 1994d), Benoit et al. (1993), Ankley et al. (1991, 1992a, 1992c, 1994).

General Acceptability Ranges for Ammonia in Marine and Estuarine Amphipod Sediment Toxicity Tests.

Parameter	*Rhepoxynius*	*Ampelisca*	*Eohaustorius*	*Leptocheirus*
Ammonia (total mg/L, pH 7.7)	<30	<30	<60	<60
Ammonia (unionized mg/L, pH 7.7)	<0.4	<0.4	<0.8	<0.8

The chemistry and toxicology of sulfides is less well-understood than that of ammonia. However, sulfides are not likely to be a problem in most open-water situations, or in bioassays where adequate oxygen levels are maintained in the overlying water.

11.2.3 Chronic/Sublethal Tests

Chronic/sublethal responses to sediment are presently only available, in addition to the end-point of survival, for a very few toxicity tests, for example: the amphipods *Hyalella azteca*, *Ampelisca abdita* and *Leptocheirus plumulosus;* the midges *Chironomus tentans* and *C. riparius*; the oligochaetes *Tubifex tubifex* and *Lumbriculus variegatus,* and the polychaete *Neanthes arenaceodentata.* [Note: EPA has recently developed chronic sediment toxicity test methods for freshwater organisms (*C. tentans and H. azteca*). EPA and USACE are jointly developing a chronic sediment toxicity test method manual for marine and estuarine organisms (*L. plumulosus*). These documents are currently under review and will be published as standard methods manuals.] Unlike acute toxicity tests, there is presently no consensus as to what level of chronic/sublethal effects (e.g., reduction of growth, reproduction, fecundity, survival of young) is cause for concern. Further, there is also no consensus as to when such effects would preclude disposal or would constitute unacceptable adverse effects requiring some type of management action. Hence, chronic/sublethal tests are not presently part of Tier III in this national manual. However, regional testing manuals may apply appropriate chronic/sublethal tests to sediments in advance of their inclusion in this national manual provided this is done with a benchmark species (e.g., *C. tentans*) or *in addition to* the benchmark testing.

Guidance for conducting the above tests may be found in publications including Nebeker and Miller (1988), Nebeker et al. (1984), Johns and Ginn (1990), Johns et al. (1990), Ingersoll and Nelson (1990), Dillon et al. (1993), Phipps et al. (1993), McGee et al. (1993). Burton (1991) provides a comprehensive review of freshwater sediment toxicity tests. Survival and growth are the endpoints of all of these tests. In addition, some tests also measure reproductive end-points.

Criteria for control acceptability for chronic/sublethal tests are specific to the test and organism. If control criteria are exceeded, the test must be repeated.

11.2.4 Data Presentation and Analysis

Data Presentation

The data for each test species should be presented in separate tables that include the following information:

- scientific name of the test species

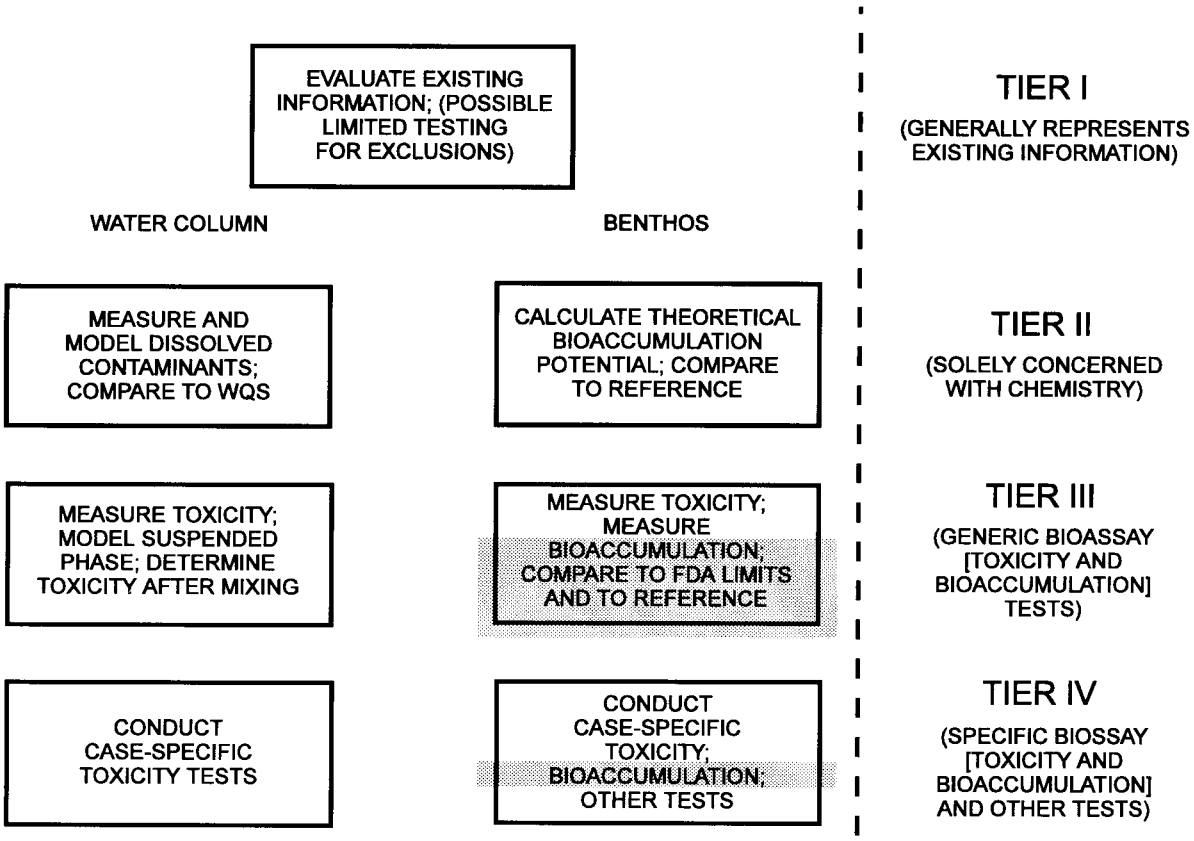
- number of organisms in each treatment at the start of the test
- number of organisms recovered alive and/or in normal health from each chamber at the end of the test (including positive and negative controls)
- information regarding emergence, burrowing, tube building, behavioral abnormalities, growth, reproduction, and any other observations
- water-quality data for each test chamber for each day.

Data Analysis

It is possible that neither mortality nor other effects will be observed in any of the treatments or that survival in the dredged material will be equal to or higher than survival in the reference or control sediments. In either of these situations, there is no need for statistical analysis and no indication of adverse effects due to the dredged material. Similarly, if survival is higher in test sediments than in the control, but lower than in the reference area, and control survival is at acceptable levels (i.e., 90% or greater survival), there is no need for statistical analysis and no indication of benthic toxicity due to the dredged material. However, if survival in the reference sediment is higher than in the dredged material treatments and exceeds the allowable percent difference between the two treatments, the data have to be analyzed statistically to determine whether there is a significant difference between the reference and dredged material. Statistical procedures recommended for analyzing benthic acute toxicity data are described in detail in Appendix D. Local guidance must be developed to interpret chronic/sublethal tests.

11.2.5 Conclusions

Guidance on the use of the results to reach a determination is provided in Section 6.2.



11.3 Tier IV: Chronic/Sublethal Effects Evaluations

At present, it is not appropriate to incorporate sediment chronic/sublethal effects testing in this national manual (see Sections 6.0 and 11.2.3). When standardized chronic effects tests are approved, they will be incorporated in Tier III. Until then, such non-standard tests should be used in Tier IV except where regional testing manuals apply such tests in advance of their inclusion in future revisions of this national manual, provided this is done with a benchmark species or *in addition to* the benchmark testing.

11.4 Tier IV: Case Specific Evaluations

Biological effects tests in Tier IV should be used only in situations that warrant special investigative procedures. They may include chronic/sublethal tests, field studies such as benthic infaunal studies (EPA, 1992), experimental studies such as *in situ* toxicity tests or toxicity identification evaluation (Ankley et

al., 1992a), risk assessments and/or no effects levels for aquatic life. In such cases, test procedures have to be tailored for specific situations, and general guidance cannot be offered. Such studies have to be selected, designed, and evaluated as the need arises, with the assistance of administrative and scientific expertise from EPA and USACE, and other sources as appropriate.

12.0 GUIDANCE FOR PERFORMING BIOACCUMULATION TESTS

Bioaccumulation is defined in relation to disposal activities in the Definitions section at the beginning of this manual.

12.1 Tier III: Determination Of Bioavailability

Bioavailability tests are designed to evaluate the potential of benthic organisms to bioaccumulate contaminants of concern from the proposed dredged material. Lee et al. (1989) and Boese and Lee (1992) discuss bioaccumulation methodology in detail and may be followed on any matter that does not conflict with this manual. Tier III bioavailability tests are based on analysis of tissues of organisms after 28 d of exposure (see Section 6.3). Although time series testing is a component of Tier IV bioaccumulation testing, it may also be appropriate in Tier III, for instance where K_{ow} values are greater than 5.5 (see Section 12.2.1).

12.1.1 Species Selection and Apparatus

The selection of aquatic organisms for use in the determination of bioaccumulation will depend on their inability to metabolize some types of organic compounds, and their ability to survive exposure to the test sediments. Two species should be used in bioaccumulation testing where possible (Table 12-1), unless adequate regional data are available to justify single species testing. Test species should provide adequate biomass for chemical analysis, and preferably ingest sediments and survive in dredged material and control and reference sediments equally well (or where differences can be accounted for). The rationale for testing more than a single species is to cover the range of differing species contaminant accumulation and to be environmentally protective. Of the species tested, at least one must be a benchmark species; however, this does not preclude the use of more than one benchmark species. Non-benchmark species listed in Table 12-1 can achieve benchmark status if a summary of test conditions and test acceptability criteria similar to the starred benchmark species are provided that meet the required species characteristics criteria. To be technically justified, species proposed for use regionally and not listed in Table 12-1 would also need to meet the species characteristics criteria and proponents should provide a summary of test conditions and test acceptability criteria except where species are to be tested *in addition to* the benchmark species. In this latter case, this information is desirable but not needed.

Table 12-1. Candidate Test Species for Determining Potential Bioaccumulation from Whole Sediment Tests. Details of testing procedures are provided in Appendix E; additional guidance is provided in EPA (1994c,d).

Polychaetes

*Neanthes arenaceodentata** (N)
*Nereis virens** (N,E)[a]
Arenicola marina (N)

Oligochaetes

Lumbriculus variegatus (F)*

Insect Larvae

Mayfly, *Hexagenia limbata* or sp. (F)

Bivalves

Macoma clam, *Macoma nasuta**(N,E)[a]
Yoldia clam, *Yoldia limatula* (N)

Crustaceans

Diporeia sp. (F)

Note: Examples are not presented in order of importance; however, the asterisks indicate recommended benchmark species. Other species may be designated in future as benchmark species by EPA and USACE when the data on their response to contaminants are adequate. Only benthic species should be tested. Although sediment ingesters are preferable, intimate contact with sediment is acceptable.

Only tests which do not require feeding of the organisms are included. Feeding is a research issue; for the present, food is not to be added because it provides additional organic carbon and can alter contaminant partitioning during testing.

For the purpose of this manual, related to the tolerances of the test animals, (F) = Freshwater, salinity ≤ 1‰ (N) = Near Coastal, salinity ≥ 25‰ (E) = Estuarine, salinity 1-25‰. It is recognized that the commonly accepted salinity range for estuaries is 1-35‰ and near coastal water is usually greater than 30‰ salinity.

[a] *Macoma nasuta* and *Nereis virens* bioaccumulation tests are in the process of standardization by EPA; it is expected that these will, in future, be the primary benchmark species for near coastal waters. Further, these two species can be used in estuarine waters down to appropriate low levels of salinity (see Appendix E).

Apparatus to be used for testing is described in Section 11.2.2. Additional requirements for voiding gut contents are described in Section 12.1.2. Species characteristics to consider when designing bio-accumulation tests include, not in order of importance:

- readily available year-round
- provide adequate biomass for analysis
- preferably ingest sediments
- preferably high in lipids
- survive in dredged material and control and reference sediments equally well, allowing adequate tissue for analysis
- tolerate handling and laboratory conditions
- related phylogenetically and/or by ecological requirements to species characteristic of the disposal site area in the season of the proposed discharge
- important ecologically, economically, and/or recreationally
- inefficient metabolizers of contaminants, particularly PAH.

Regional scientists and regulatory personnel should be consulted for additional guidance. A minimum amount of tissue is required for analysis, otherwise it will be impossible to quantify the amount of contaminant present (Section 9.5.2). Examples of the amounts of tissue which may be required are provided in Table 8-2. However, the amounts shown are not set amounts; more or less may be required depending on the analytes, matrices, detection limits, and particular analytical laboratory. If the biological needs of the organisms or adequate voiding (e.g., clams) require the presence of sediment, uncontaminated sand should be used (Section 12.1.2). Data in the form of "concentration below detection limits" are not quantitative; definitive concentration measurements are the goal, where such are possible within reasonable method and target detection limits.

12.1.2 Experimental Conditions

Test conditions are similar but not identical to those described in Section 11.2.2 for whole sediment toxicity tests. Overlying water renewal may be required to maintain adequate water quality. Food or additional sediment should not be provided during the test. Control animals should be sampled and archived at both the beginning and the end of testing. If discrepancies are found during data analysis, the archived samples can be analyzed to possibly resolve any problem(s). Due care should be taken not to exceed species-specific biomass loadings (overcrowding; APHA, 1989).

Digestive tracts of the animals should be emptied or removed immediately after termination of the exposure period. Sediment in digestive tracts may contain inert constituents and the contaminants of concern in forms which are not biologically available but which may be incorrectly identified as such during chemical analysis (e.g., see Lobel et al., 1991).

If the animals are large enough to make it practical, the best procedure is to excise the digestive tract. However, test organisms are seldom large enough to allow this, and most organisms have to be allowed to void the material, in separate aquaria in clean, sediment-free water. Some organisms will pass material through the digestive tract only if more material is ingested. These animals have to be purged in aquaria with clean sand. Animals are not fed during the purging period. Fecal material is siphoned from the aquaria twice during the 24-h purging period. To minimize the possibility of loss of contaminants from tissues, purging for longer periods is not recommended. Shells or exoskeletons which generally contain low levels of contaminants are, where possible, removed and not included in the analysis as their weight would give an artificially low indication of bioavailability.

An initial time-zero of each sample is collected for tissue analysis. Tissue contaminant concentrations in control animals must be determined to ensure that background levels are not inordinate. Although procedures for Tier III and IV laboratory bioaccumulation tests have been discussed separately, it may be possible to combine these procedures in practice. This can be done by following the steady state (Tier IV) bioaccumulation procedure which involves sequential time-series analyses, but initially analyzing only the 28 d sample and freezing the other samples. If these data, as part of the Tier III bioavailability evaluation, do not allow a determination to be made, then the remaining time series samples may be analyzed and used in the Tier IV steady-state bioaccumulation evaluation.

12.1.3 Chemical Analysis

Chemical analysis will involve some or all of the contaminants identified in Sections 4.2 and 9.5.1. Analytical procedures are provided in Section 9.5.2.

12.1.4 Data Presentation and Analysis

Data Presentation

Data should be presented in tabular format, listing tissue concentration of each contaminant, by organism and by sediment type (e.g., dredged and reference). Similar information to that detailed in Section 11.2.4

should be provided. Although bioaccumulation species/tests cannot be used to determine toxicity requirements, any mortalities which occur during bioaccumulation testing must be documented.

Data Analysis

Contaminant tissue concentrations in test organisms are statistically compared to the FDA Action Levels (Table 6-1) (refer to Figure 3-3). These tissue concentrations are also statistically compared with reference organism concentrations (Appendix D). In some cases, tissue concentrations in organisms exposed to one or more of the dredged-material samples may be less than or equal to reference organism concentrations. Providing the reference data are appropriate, this result indicates that bioavailability of the contaminants of concern in the dredged material is not greater than in the reference area sediment.

The sample of organisms archived at the initiation of the exposure can be useful in interpreting results. It can add perspective to the magnitude of uptake during the exposure period. In some cases, elevated body burdens may not be due to the dredged material or reference sediment, but may have been already present in the organisms at the start of the test.

12.1.5 Conclusions

Guidance on reaching a determination is provided in Section 6.3.

12.2 Tier IV: Determination Of Steady State Bioaccumulation

Tier IV bioaccumulation evaluation, if necessary, provides for determination, either by laboratory testing (ASTM, 1984) or by collection of field samples, of the steady state concentrations of contaminants in organisms exposed to the dredged material as compared with organisms exposed to the reference site material. Testing options include longer laboratory exposures (not discussed), collection of organisms living in the material to be dredged and at the reference site for body burden determinations (Section 12.2.2) or *in situ* exposures using transplanted organisms, for instance caged mussels (not discussed). Tier IV determinations follow the guidance in Section 7.2.

12.2.1 Laboratory Testing

The necessary species, apparatus and test conditions for laboratory testing are those for Tier III bioaccumulation testing (see Sections 12.1.1 and 12.1.2). Tissue samples taken at different times during

the exposure period provide the basis for determining the rate of uptake and elimination of contaminants. From these rate data, the steady state concentration of contaminants in the tissues can be calculated, even though the steady state might not have been reached during the actual exposure. For the purposes of this test, steady state is defined as the concentration of contaminant that would occur in tissue after constant exposure conditions.

An initial time-zero sample of each species is collected for tissue analysis. Additional tissue samples are collected from each of the five replicate reference and dredged-material exposure chambers at intervals of, for instance, 2, 4, 7, 10, 18, and 28 d. It is critical that enough tissue is available to allow for interval body burden analyses at the specified detection limits.

Complete tissue concentration data should be presented in tabular format. Recommended statistical methods for fitting a curve to determine steady-state tissue concentration are provided in Appendix D. The statistical procedures use an iterative curve-fitting process to determine the key variables ($k_1 C_s$ the uptake rate-constant times the contaminant concentration in the sediment, and k_2 the depuration rate constant). An initial value for C_s has to be supplied. When the sediment concentration of the contaminant of concern is used, the ratio of k_1/k_2 is the sediment bioaccumulation factor (BAF) (Lake et al., 1987; Rubinstein et al., 1987), the ratio of steady-state tissue concentration to sediment concentration.

A determination is made based on the magnitude of bioaccumulation from the dredged material, its comparison with the available FDA levels, steady-state bioaccumulation from the reference sediment, and the body burden of reference organisms. Guidance for making determinations based on these comparisons is provided in Section 7.2 and can include risk assessment and no effects levels for aquatic life.

Guidance on quality assurance/quality control (QA/QC) considerations for bioaccumulation testing are provided in Appendix G.3.17 and EPA (1995).

12.2.2 Field Assessment of Steady State Bioaccumulation

Field sampling programs obviate difficulties related to quantitatively considering field-exposure conditions in the interpretation of test results, since the animals are exposed to the conditions of mixing and sediment transport actually occurring at the disposal site. Difficulties related to the time required to conduct laboratory bioaccumulation studies are also overcome if organisms already living at the disposal site are used for field bioaccumulation studies. This approach is technically valid for predictive purposes only where there is a true historical precedent for the proposed operation being evaluated. That is, a field assessment can be used only where the quality of the sediment to be dredged can be shown not to have deteriorated

or become more contaminated since the last dredging and disposal operation. In addition, disposal has to be proposed for the site at which the dredged material in question has been previously disposed or for a site of similar sediment type supporting a similar biological community. This approach is generally not appropriate for multi-user disposal sites. Knowledge of the contaminant body burden of the organisms living around the proposed disposal site is used in evaluating bioaccumulation results in Tier IV (Section 7.2).

12.2.2.1 Apparatus

Major items required include:

- a vessel capable of operating at the disposal site and equipped to handle benthic sampling devices; navigation equipment has to allow precise positioning
- sampling devices such as a box corer, Smith-MacIntyre, Van Veen, Petersen, Ponar, Ekman or other benthic grab
- stainless steel screens to remove animals from the sediment
- tanks for transporting the animals to the laboratory in collection site water
- laboratory facilities for holding the animals prior to analysis
- chemical and analytical facilities as required for the desired analyses.

12.2.2.2 Species Selection

The species selected for analysis have to be present in sufficient numbers for adequate sample collection at all stations and to provide sufficient tissue for analysis (see Section 12.1.1). The same species must be collected at all stations because bioaccumulation cannot be compared across species lines. If these conditions cannot be met, the field assessment approach cannot be implemented.

If possible, several samples of sufficient size for analysis should be collected at each station to provide a statistical estimate of variability in tissue contaminant content. Collection of more than one sample per station, however, may prove impractical if a composite of many small organisms has to be used or if suitable organisms are not abundant at the disposal site.

To minimize the numbers and collection effort required, it is desirable to select the largest appropriate species. However, highly mobile epifauna (such as crustaceans, certain molluscs, and fish) should not be used, because a relationship cannot be established between their location when collected and their

body burden at the time of collection. Therefore, relatively large, immobile species are the most desirable organisms. However, analyses should not be conducted on single organisms as the objective is to obtain representative data for the entire population of organisms. Any relatively immobile species collectable in sufficient numbers at all stations may be used, but the required collection effort increases sharply as organism size decreases.

As discussed previously, if PAH are contaminants of concern, it is essential that bioaccumulation studies include one or more species with very low ability to metabolize PAH. Bivalve molluscs and oligochaetes are widely accepted as meeting this requirement.

12.2.2.3 Sampling Design and Conduct

Sufficient tissue to obtain definitive body burden data has to be collected using the same species from each of at least three stations within the disposal site boundaries and from an acceptable reference site. It is mandatory that several stations be sampled, rather than collecting all of the animals at one station, in order to provide a measure of the variability that exists in tissue concentrations in the animals in the area. Samples from all stations should be collected on the same day if possible.

12.2.2.4 Basis for Evaluation of Bioaccumulation

Evaluations are made by comparison to contaminant concentrations in field organisms living around, but not affected by, the disposal site, similar to the reference area approach (Section 3.1). In this case, reference data involve at least three stations located in an uncontaminated material sedimentologically similar to that within the disposal site, in a direction perpendicular to (i.e., not in the direction of) the net bottom transport. If the direction of net bottom transport is not known, at least six stations surrounding the disposal site should be established in sediments sedimentologically similar to those within the disposal site.

12.2.2.5 Sample Collection and Handling

Repeated collections should be made at the same location until an adequate tissue volume is obtained. Gently wash the sediment obtained by the sampler through 1-mm mesh stainless-steel screens, and place the retained organisms of the desired species in holding tanks.

Label the samples clearly and return the organisms to the laboratory, being careful to keep them separated and to maintain nonstressful levels of temperature and dissolved oxygen. In the laboratory, maintain them in clean water in separate containers. Do not place any sediment in the containers and do not feed the organisms. Immediately discard any organisms that die. Remove sediment from the digestive tracts of the organisms and, as possible, shells or exoskeletons (Section 12.1.2).

12.2.2.6 Chemical Analysis

Chemical analysis will involve some or all of the contaminants identified in Sections 4.2 and 9.5.1. Analytical procedures are provided in Section 9.5.2.

12.2.2.7 Data Presentation and Analysis

Complete tissue concentration data for all samples should be presented in tabular format as previously described. Since Tier IV testing will generally use non-standard methods and approaches, complete documentation is critical. Recommended statistical methods presented in Appendix D may not include all data analyses necessary for all Tier IV tests.

12.2.2.8 Conclusions

A determination is made based on the magnitude of bioaccumulation in organisms collected within the boundaries of the reference site, compared with bioaccumulation in organisms living within the area to be dredged. Guidance for making a determination based on these comparisons is provided in Section 7.2.

1. Introduction

1.1 General

This evaluation has been prepared to summarize the field activities and analytical results associated with a soil investigation performed at Parcel J, a federally owned parcel along the Fox River in Kaukauna, Wisconsin, managed by the U.S. Army Corps of Engineers (USACE) (Figure 1). The U.S. Army Corps of Engineers (USACE) performed this field investigation to gather data necessary to evaluate soil contaminant concentrations within site soils.

In August 2020, the Wisconsin Department of Natural Resources (WDNR) issued a letter indicating that USACE was responsible for the investigation and remediation of contaminated soil on Parcel J (BRRTS #02-45-548419). Parcel J has previously been investigated by USACE in 2001, 2003, 2004 and 2005 as part of the larger transfer of federal properties associated with the Fox River navigation system to the State of Wisconsin. The Memorandum of Agreement (MOA) between the Department of the Army and the State of Wisconsin (dated September 11, 2000) provides that "Subject to the availability of funds and based on the Environmental Baseline Studies to be completed pursuant to paragraph C.2. of this Article, the Government agrees to complete any necessary remediation action required by the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) and provide the applicable warranties and covenants required by section 120(h) of CERCLA." Due to elevated lead concentrations within the western portion of Parcel J (west of the Kaukauna Power Canal) this portion of the parcel was not transferred with the rest of the Fox River properties (the eastern portion was retained by USACE for operation and maintenance of the adjacent federal dam). USACE will perform this field investigation to gather data necessary to evaluate soil lead concentrations along the western portion of Parcel J.

The field activities describe within this Technical Memorandum are consistent with the elements set forth in the CERCLA (CERCLA; 42 [USC] 9601 et seq.), as amended; the National Contingency Plan (NCP) of March 8, 1990 (40 Code of Federal Regulations [CFR] Part 300).

A Field Sampling Plan (FSP) and Quality Assurance Project Plan (QAPP) were developed and comprise the Sampling and Analysis Plan (SAP) for the SI. The SAP provided a consistent framework of policies, procedures, functional activities and organization that were used during field and laboratory activities related to the acquisition of chemical data. The QAPP outlined the Quality Assurance (QA) program and Quality Control (QC) procedures that were used to verify and maintain the level of performance required to meet the project objectives. An Activity Hazard Analysis (AHA) was prepared for the SI field activities and attached as Appendix A of the SAP (USACE, 2021).

1.2 Site Description

Parcel J is located on the Lower Fox River in the City of Kaukauna, Outagamie County, WI, approximately 40 kilometers (km) [25 miles (mi)] southwest of Green Bay (Figure 1). Parcel J is approximately 2.4 acres, with the parcel bisected into two portions by the Kaukauna Power

Canal. The western portion is a thin strip of land along the south shore of the Fox River on the west side of the Kaukauna Power Canal, approximately 700 feet long and 25 to 50 feet wide (0.6 acres), and the eastern portion is about 1.8 acres between the Fox River and east side of the Kaukauna Power Canal, at the Fox River U.S. Dam Right Abutment. The eastern portion is associated with USACE operation and maintenance of the Dam. A portion of the parcel downstream of the Dam (0.5 acres) was transferred to the State of Wisconsin. The western portion of Parcel J is abutted by several residential apartment complexes and the eastern portion is abutted by a city park.

Previous investigations of the western portion of Parcel J indicate that lead concentrations within shallow soils (0-4 feet) sporadically exceed the residential direct contact screening level of 400 mg/kg, ranging from 15 to 11,000 mg/kg. Shallow soils generally consist of historic fill made up of sand and gravel with silty clay. The fill is underlain by native glacial till (red-brown silty clay) to a depth of 10 to 15 feet, at which contact with bedrock is assumed. Groundwater is present at depths of 7 to >10 feet, although wells probed to a depth of 15 feet produced only limited quantities of water for sample collection due to the low hydraulic conductivity of the overburden soils. Shallow groundwater flow is to the south, moving away from the Fox River. Previous groundwater sampling on the parcel indicated lead was not detectable at a detection limit of 1 µg/L.

Parcel J is designated by the Wisconsin Department of Natural Resources (WDNR) in the Bureau for Remediation and Redevelopment Tracking System (BRRTS) as No.02-45-548419.

1.3 Site History

In 1872, the USACE acquired navigational control of the Fox River waterway, between the cities of Menasha and De Pere, Wisconsin.

By the 1940s, the Fox River, which originally played a major role in regional transportation and commerce, saw a major decline in navigation with the advent of railroads and highways. The Upper Fox River locks (Portage to Lake Winnebago) were abandoned by the USACE in 1962. In 1983, the USACE closed the Lower Fox River to commercial traffic and discontinued operation and maintenance of the locks and placed its property holdings in caretaker status. The USACE continued to own and operate nine federal dams and retain control over four privately-owned dams on the Lower Fox River, however, as part of its flood control responsibilities.

Beginning in the 1980's, an effort began to transfer ownership of the locks from the USACE to the State of Wisconsin with the goal of renovating and reopening the locks for commercial and recreational boating. In preparation for this transfer, a MOA was signed on September 11, 2000 (USACE 2015) by the Wisconsin Governor, the Secretary of the WDNR, and the Assistant Secretary of the Army for Civil Works. In the MOA (Paragraph B of Article I), the federal government agreed to "complete any necessary remediation action required by the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) and to provide the applicable warranties and covenants required by Section 120(h) of CERCLA."

In 2001, the FRNSA was created to manage the Fox River Locks following this transfer of ownership of the system from the USACE to the State of Wisconsin DOA. As specified in Chapter 237, Wisconsin Statutes, the FRNSA's primary mission is to repair, rehabilitate, operate and maintain the locks system.

On September 17, 2004, the USACE began transferring the ownership of the 17 locks, 38 ha (94 ac) of land bordering the Lower Fox River, three harbors, and an assortment of related buildings along the Lower Fox River to the Wisconsin DOA. The western portion of Parcel J was not included in this transfer due to the presence of lead contamination in soil.

The area west of the Kaukauna Power Canal was historically used as a rail service/maintenance yard, including carpentry, machine, blacksmith, tin, and repair shops, supply warehouses, engine and coal rooms, and a roundhouse for locomotive maintenance, by the Chicago and Northwestern Railway from the late 1800s through the 1980s, until being redeveloped as residential apartment complexes (Partner 2018). The western portion of Parcel J is located along the northern periphery of the historic rail service/maintenance yard, with historic development in the form of buildings and tracks occurring to the south.

A Phase 1 Environmental Site Assessment (ESA) and Environmental Baseline Survey of the Fox River properties was conducted in 2000 (Barr 2000). A review of this assessment does not indicate that products containing emerging contaminants, including PFAS, were produced, used, handled or stored at the site. Previous investigations indicate that historic fill along the western portion of the parcel is sporadically impacted by elevated concentrations of lead. USACE has not had any discernable historic use of this portion of the property.

1.3.1 Previous Investigations and Remedial Activities

The eastern portion of Parcel J was investigated in 2001, after a Phase I Environmental Site Assessment (ESA) indicated potential recognized environmental conditions (RECs) including historic surface disturbances and historic industrial use by the Kaukauna Water Power Company (Barr 2000). Three temporary groundwater wells were installed and sampled for volatile organic compounds (VOCs) (Kc-1-01, Kc-2-01, and Kc-3-01) and three soil borings were collected for analyses of soil polychlorinated biphenyls (PCBs) and metals (Kd-1-01, Kd-2-01, Kd-3-01) (Altech 2001). Soil metal concentrations were below screening criteria (lead concentrations ranged from 39 to 291 mg/kg) and PCBs were not detectable in soil. VOCs were not detected in groundwater except for low level detections of toluene and ethyl benzene, which were below screening criteria. Soils generally consisted of reddish brown moderately hard and moderately plastic silty clay (glacial till) with minor percentages of sand and gravel, with increased sand and gravel occasionally in the upper 2 to 3 feet. Fill material was occasionally encountered, consisting of dark brown to black sandy clay, with cinders, wood fragments, gravel, and concrete fragments intermixed with portions of native clay soil. Groundwater was encountered at depths of 9 to 10 feet; however, the wells were extremely slow to recharge, indicating the clayey soils to be of low permeability.

The western portion of Parcel J was initially investigated in 2003 to address the potential impact of past adjacent industrial use (Altech 2006). Soil was sampled and analyzed for metals and VOCs from three locations at depth intervals of between 0 and 2 feet below ground surface.

Lead was identified as the contaminant of concern for the property as lead concentrations ranged from 61 to 320 mg/kg, greater than the then non-industrial direct contact screening criteria of 250 mg/kg. Further sampling occurred in 2004, in which 17 locations were sampled to a maximum depth of 4 feet. Soil borings were screened at 0.5 to 1.0 foot intervals with an XRF to profile lead concentrations. XRF lead concentrations ranged from < 30 mg/kg to 4,000 mg/kg, with the highest concentrations occurring within the 0-2-foot depth interval. The bottom depth interval of each soil boring was submitted for laboratory analysis of lead. Laboratory determined lead concentrations ranged from 18 to 11,000 mg/kg at depths of 0.5 to 4 feet below ground surface. To further characterize soil lead concentrations across the soil profile, ten soil borings were collected in 2005 to depths of 8.5 to 10 feet below ground surface. Soil was sampled and analyzed for lead at depth intervals of 0-2 feet, 4-6 feet, and 7-9 feet. Soil lead concentrations in the 0-2 feet interval ranged from 15 to 2,100 mg/kg, compared to a range of 3.3 to 79 mg/kg across the deeper intervals. Samples for toxic characteristic leaching procedure (TCLP) and synthetic precipitation leaching procedure (SPLP) testing were collected from the two locations with the highest lead concentrations (440 mg/kg and 2,100 mg/kg). TCLP results ranged from 0.85 to 1.1 mg/L, below the hazardous waste threshold of 5.0 mg/L. The SPLP results ranged from 27 to 330 µg/L, above the WDNR groundwater preventive action limit and enforcement standard for lead of 1.5 µg/L and 15 µg/L, respectively. Three temporary groundwater wells were also installed to depths of 15 feet, however only one well produced enough groundwater to be sampled, again indicating very slow recharge rates from the predominantly clay soils. Lead was not detectable in the groundwater sample at a reporting limit of 1 µg/L, less than the preventative action limit of 1.5 µg/L. Across the sampling events, elevated lead levels have been limited to the upper 4 feet of soil, within the shallow fill/sand-based soil layers, with reduced lead concentrations within the deeper, native clay-based soil layers. Depth to groundwater ranged from 7 to greater than 10 feet. Across the three sampling events, 50 samples were collected across 30 locations, with lead concentrations greater than the residential direct contact screening criteria in 10 of the 50 total samples, and at 10 of the 30 locations. Most of the elevated results within the western portion of Parcel J are located across the eastern half toward the Power Canal.

Three adjacent properties associated with the historic rail service/maintenance yard have recently been the subject of environmental investigations: Fox Shores apartments (BRRTS #02-45-582746), Ghost Town Fitness (BRRTS #02-45-5479110), and the Roundhouse Manor apartments (BRRTS #07-45-559282) (Figure 2). These properties housed most of the buildings and rail spurs associated with the rail yard and are down gradient of Parcel J.

The Fox Shores apartment complex immediately south of the western portion of Parcel J has been subject to various remedial investigations from 2018 to 2020, including sampling of 27 soil borings to depths of between 1.5 and 10 feet, and 5 groundwater wells (Stantec 2020). Soil samples generally consisted of silty clay, with some sand and gravel layers and fill layers within the upper 4 feet. Samples were collected primarily from the 0-2 and 2-4 feet intervals for laboratory analysis of polycyclic aromatic hydrocarbons (PAHs), VOCs, and RCRA metals. Groundwater was sampled in the fall and the spring for PAHs, VOCs and RCRA metals. Groundwater was generally encountered at 4 to 6 feet below ground surface, and the wells were able to be purged dry, again owing to the low hydraulic conductivity of the mainly clay soils. Groundwater flow was toward the south, moving away from the Fox River and Parcel J. Across

two rounds of groundwater sampling, arsenic was above the preventive action limit of 1 µg/L in 3 of the 5 wells, with concentrations ranging from 1.3 to 17 µg/L in those wells, with one instance of being above the enforcement standard of 10 µg/L. Arsenic is a naturally occurring constituent in soil and groundwater and is sometimes found at high levels (>10 µg/L) in groundwater in Outagamie County (WDNR 2021). Concentrations of benzo(a)pyrene (0.36 µg/L), benzo(b)fluoranthene (0.29 µg/L), and chrysene (1.5 µg/L) were detected above the groundwater enforcement standard of 0.2 µg/L across three separate wells, however, were believed to be associated with suspended solids within the sample, rather than mobile dissolved results. VOCs were not detected at levels above groundwater screening criteria. Based on these results it was concluded that groundwater impacts were minimal, with site soil contaminants not significantly impacting groundwater quality. The soil sampling results indicated the widespread presence of historic urban fill consisting of clay with sand/gravel present at depths of up to 3 feet, underlain by native silty clay soil. Within the shallow soil samples (0-4 feet), arsenic, lead, and various PAHs were occasionally detected above residential direct contact screening criteria. Arsenic was detected above the background threshold value of 8 mg/kg in 12 of 27 samples, with a maximum concentration of 240 mg/kg and lead was detected above the residential direct contact criteria of 400 mg/kg in 7 out of 27 samples with a maximum concentration of 97,000 mg/kg. Benzo(a)anthracene, benzo(a)pyrene, benzo(b)flouranthene, dibenzo(a,h)anthrathene and indeno(1,2,3-cd)pyrene were the PAHs detected above residential direct contact criteria, with benzo(a)pyrene most often exceeding criteria, with 21 out of 31 results above the criteria of 0.115 mg/kg. When compared to typical urban background soil concentrations, 5 out of 31 results exceeded 95% Upper Confidence Limits for PAHs in Milwaukee undisturbed soils (Siemering and Thiboldeaux 2021). These conditions were associated with apparent petroleum impacted soils sporadically located between the apartment buildings north of Bicentennial Court and along landscaped areas adjacent to Bicentennial Court and Fox Shores Drive. VOCs were not detected above screening criteria.

The property immediately southeast of the Fox Shores apartment complex, Ghost Town Fitness Center, was subject to soil and groundwater sampling and analysis in 2006. A soil boring and groundwater well were installed to evaluate potential environmental impacts associated with the historic use as a rail service/maintenance yard (Terracon 2006). Specifically, this area historically consisted of the machine shop, blacksmith, and locomotive roundhouse. Soil and groundwater were analyzed for diesel range organics, VOCs, and RCRA metals. Groundwater was encountered at 4 feet below ground surface. Soil concentrations did not exceed screening criteria, however there were minor exceedances of the groundwater preventive action limit for arsenic (3 µg/L compared to 1 µg/L) and selenium (14.7 µg/L compared to 10 µg/L). Based on these results the site was granted a PAL exemption and closure in 2006.

The property immediately east of Ghost Town Fitness Center, the Roundhouse Manor apartments, was investigated in 2012 to address potential environmental impacts associated with the historic use of the site, including housing the railroad roundhouse, turn table, sand house, water tank, coal shed, hoist and coal dump, and rail spurs. Four soil borings were collected to depths of 10 to 16.5 feet, with two borings converted to temporary monitoring wells. Groundwater was present at 10.5 to 12.5 feet below ground surface. Soil and groundwater were sampled and analyzed for total petroleum hydrocarbons – diesel range organics (TPH-DRO), metals, VOCs, and PAHs. Low levels of arsenic (5.6 mg/kg to 11.4 mg/kg), lead (105 mg/kg to

133 mg/kg), and TPH-DRO (151 mg/kg to 170 mg/kg) were detected in soil samples above screening criteria and PAHs benzo(a)anthracene, benzo(a)pyrene, and phenanthracene were detected above the preventive action limit in groundwater. To further evaluate groundwater conditions, groundwater was resampled from a more robustly developed monitoring well, with no exceedances determined. Based on these results, the site was granted a no further action required determination.

Based on the previous investigations of the western portion of Parcel J, lead concentrations within shallow soils (0-4 feet) sporadically exceed the residential direct contact screening level of 400 mg/kg. Shallow soils generally consist of historic fill made up of sand and gravel with silty clay. The fill is underlain by native glacial till (red-brown silty clay), which is of low hydraulic conductivity, limiting groundwater flow and infiltration. Groundwater is present at depths of greater than 7 feet and flows to the south, moving away from the Fox River and Parcel J. Previous groundwater sampling on the parcel and on adjacent, downgradient properties, confirm limited impacts to groundwater from soil contaminants. Contaminant conditions are assumed to be associated with the historic development of the adjacent area to the south as a rail service/maintenance yard.

2. Project Scope and Objectives

The objective of the field work and analysis described in this section is to define contaminant concentrations in fill and soils along the western portion of Parcel J. Based on the previous investigations on Parcel J and adjacent parcels, RCRA metals and PAHs in surficial soils require further evaluation.

2.1 Definition of the Problem

Soil sampling and analysis is needed to determine the extent that soils may need to be remediated along the western portion of Parcel J due to lead and/or PAH contamination (Figure 2). The USACE proposed this field investigation to determine the horizontal and vertical extent of contaminant impacted soil along the western portion of Parcel J.

2.2 Project Objectives

The following Data Quality Objectives (DQOs) were established for the SAP following the USEPA DQO process. The SAP DQOs were established using available previous site investigation data to evaluate potential remedial activities associated with the handling and/or removal of impacted material.

The objectives for the field investigation were:

- Determine whether soil contaminant concentrations along the western portion of Parcel J represent a risk to human health.
- Determine the horizontal and vertical extent, and volume of contaminated soil that may have to be remediated.

2.3 Project Action Levels

The western portion of Parcel J is undeveloped and USACE has no active use of the area. However, this portion of the parcel is adjacent to several residential apartment complexes. As such, apartment residents may come into contact with site soil if they enter the parcel. To evaluate the potential risk to apartment residents from direct contact with parcel soils, the USEPA Regional Screening Level (RSL) and Regional Removal Management level (RML) for lead in residential soil of 400 mg/kg will be used as a screening criterion (USEPA 2021a,b). This represents the USEPA screening level for lead in soil for residential land use (USEPA 1994).

PAH data will be reviewed based on USEPA residential direct contact RSLs (target cancer risk [TR]=1E-06; target hazard quotient [THQ]=0.1), regional urban background concentrations for Milwaukee, WI (Siemering and Thiboldeaux 2021), and USEPA residential direct contact RMLs (TR=1E-04; THQ=1) (USEPA 2021b).

RCRA metals data will be reviewed based on USEPA residential direct contact RSLs (TR=1E-06; THQ=0.1), Wisconsin background threshold values, and USEPA residential direct contact RMLs (TR=1E-04; THQ=1).

The RSLs are chemical specific concentrations in soil that indicate when further evaluation may be necessary under CERCLA and the RMLs are chemical specific concentrations in soil that may be used to support the decision to undertake a CERCLA removal action.

3. Field Activities

3.1 General

This section describes the field activities that were performed on May 25, 2021.

The scope of the field work and analysis included the following activities:

- Excavation of 15 test pits.
- Field classification and profiling of soil layers.
- Collection of soil samples for laboratory analysis.

3.2 Mobilization/Demobilization

The health and safety procedures outlined in the AHA were followed during performance of all on-site activities. The field investigation activities were completed in modified level D personal protective equipment (PPE).

3.3 Test Pit Excavation

Fifteen test pits were excavated along the parcel at the approximate locations shown on Figure 3. Test pits were excavated utilizing a Wacker Neuson EZ 28 Mini Excavator equipped with a 2 ft-

wide bucket. The test pits were excavated until native material or refusal was encountered, which was generally at depths of 1 – 4 feet below ground surface. Upon completion, all test pits were backfilled and compacted in one-foot lifts with the excavated spoils materials.

Samples were collected across one-foot intervals following procedures identified in the FSP (USACE, 2021). The fill and soil units encountered were documented on Test Pit logs which are provided in Appendix A.

All soil and sediment samples were shipped under chain-of-custody (COC) control to ALS Environmental Laboratory of Middletown, PA. Soil samples were analyzed for RCRA metals by EPA 6010C and PAHs (16 priority pollutants) by EPA 8270D. Three samples were analyzed for total polychlorinated biphenyls (PCBs) as aroclors by EPA 8082A. Samples with lead results greater than 400 mg/kg were also subjected to Toxicity Characteristic Leaching Procedure (TCLP) testing for metals (EPA 1311).

3.4 Equipment Decontamination

To assure that no outside contamination was introduced into the samples/data, thereby invalidating the samples/data, all non-dedicated/non-disposable equipment used during the SI was decontaminated as per the FSP (USACE, 2021).

3.5 Field Variances

Several conditions in the field made it necessary to implement modifications to excavation and sampling as presented in the FSP. Test pit locations JTP-1, JTP-8, JTP-10, JTP-12, and JTP-14 were offset slightly to avoid either a utility line or trees.

4. Sub Surface Conditions and Site Geology

Geologic conditions at the site are characterized by unconsolidated deposits overlaying consolidated/competent bedrock. The unconsolidated deposits generally consist of dark brown loam/fill ranging from 1 to 3 feet thick overlying native reddish brown clayey till. The bedrock at the site is of the Sinnipee Group which consists of tan, gray of buff dolomite with some limestone and shale (Brown, 2005). The Sinnipee Group includes Galena, Decorah and Platteville Formations. Previous soil borings indicate that depth to bedrock is greater than 10 feet below ground surface along the parcel (Altech 2006). Groundwater was not encountered in any test pit. Previous temporary monitoring wells and borings along the Parcel J indicate groundwater may be present at depths of greater than 7 feet below ground surface (Altech 2006).

5. Site Investigation Results

The USACE received data reports from ALS Environmental Laboratory and these reports were reviewed by a USACE chemist. The USACE review verified compliance with requested testing, completeness of the analytical report, and confirm the receipt of all requested deliverables. In addition, the data was verified to identify method, batch, or individual sample results which may have limitations or be unacceptable.

Table 1 presents the soil analytical results for lead, arsenic, barium, cadmium, chromium, mercury, selenium, and silver. Lead concentrations were greater than the USEPA residential screening level of 400 mg/kg on a sporadic basis across the site at locations JTP-1 (1-3 feet), JTP-2 (0-1 feet), JTP-3 (0-1 foot), JTP-9 (0-1 foot), JTP-14 (0-2 feet), and JTP-15 (1-3 feet), ranging up to 1,660 mg/kg. Lead concentrations within the top foot of soil greater than 400 mg/kg were limited to locations JTP-2 (1,660 mg/kg), JTP-3 (861 mg/kg), JTP-9 (721 mg/kg), and JTP-14 (767 mg/kg) representing 4 out of 15 locations. Lead concentrations within the top foot of soil ranged from 11 mg/kg to 1,660 mg/kg, with an average concentration of 365 mg/kg and a median concentration of 188 mg/kg. Generally, lead concentrations were highest in the surficial fill layer to depths of 1-3 feet, and decreased sharply to background levels within the underlying native reddish brown clay till. Within the underlying reddish brown soils, lead concentrations ranged from 3 mg/kg to 208 mg/kg, with an average concentration of 32 mg/kg and a median concentration of 12 mg/kg. Soil concentrations of arsenic, barium, cadmium, chromium, mercury, selenium, and silver were generally below residential direct contact RSLs or background threshold values, with the exception of low-level exceedances of arsenic and mercury collocated with elevated lead concentrations. Arsenic concentrations were greater than the background threshold value of 8 mg/kg at locations JTP-1 (1-3 feet), JTP-2 (0-1 foot), JTP-3 (0-2 feet), JTP-9 (0-1 foot), JTP-11 (0-1 foot), JTP-14 (0-2 feet), and JTP-15 (1-3 feet), ranging up to 31 mg/kg. Arsenic concentrations within the top foot of soil greater than 8 mg/kg were limited to sample locations JTP-2 (31 mg/kg), JTP-3 (27 mg/kg), JTP-9 (9 mg/kg), JTP-11 (13 mg/kg), and JTP-14 (15 mg/kg), representing 5 out of 15 samples. Arsenic concentrations within the top foot of soil ranged from 3 to 31 mg/kg, with an average concentration of 10 mg/kg and a median concentration of 6 mg/kg. Similar to lead, arsenic concentrations were lower within the underlying reddish brown soils, ranging from 2 mg/kg to 8 mg/kg, with an average and median concentration of 4 mg/kg. Mercury concentrations were only greater than the residential direct contact RSL of 1.1 mg/kg at location JTP-15, at a depth interval of 1-3 feet below ground surface. These concentrations were 2.8 mg/kg and 4.8 mg/kg, which would represent Hazard Quotients (HQ) of less than 1.

Table 2 presents the soil analytical results for PAHs. Most results were not inconsistent with typical urban background concentrations, with the exception of locations JTP-2 (0-1), JTP-4 (0-1), and JTP-6 (0-3). At these locations, concentrations of benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-c,d)pyrene exceeded USEPA residential RSLs and 95% upper confidence limits for background concentrations in Milwaukee, WI (Siemering and Thiboldeaux 2021). The concentration of benzo(a)pyrene at location JTP-4 (0-1 foot) of 11,800 µg/kg exceeded the USEPA residential RML of 11,000 µg/kg, although this result was not replicated within the field duplicate sample, which was 5,000 µg/kg. Within the top foot of soil, benzo(a)pyrene concentrations greater than the undisturbed Milwaukee soils UCL of 2,060 µg/kg were limited to locations JTP-2 (3,020 µg/kg), JTP-4 (11,800 µg/kg; 5,000 µg/kg duplicate), and JTP-6 (2,420 µg/kg). Benzo(a)pyrene concentrations within the top foot of soil ranged from 30 µg/kg to 11,800 µg/kg, with an average concentration of 1,486 µg/kg and a median concentration of 468 µg/kg. Similar to lead, in most instances PAH concentrations decrease substantially within the underlying native reddish brown clayey till, to non-detectable levels. An exception was location JTP-6, where PAH concentrations within the reddish brown clay at the interface with the fill layer were similar to concentrations within the surficial fill.

Figure 4 displays the soil lead and benzo(a)pyrene concentrations for each test pit location. Generally, soil concentrations above screening criteria are present sporadically throughout the parcel within historic surficial fill to depths of 1 to 3 feet below ground surface with decreasing concentrations within the underlying native reddish brown clayey till. These conditions are consistent with results from previous investigations on the parcel and adjacent parcels.

Table 3 presents the soil analytical results for PCBs. PCBs were not detectable in the sampled soils.

Table 4 presents the TCLP testing results for metals. All sample results were less than regulatory thresholds for the toxicity characteristic.

6. Conclusions

This soil investigation indicates that in most instances site soils meet residential screening criteria, however there are discrete areas of elevated contaminant concentrations. Currently the parcel has vegetated ground cover and is fenced, limiting contact with site soil if not disturbed. These conditions should continue to be maintained. Soils with lead concentrations greater than the USEPA screening level for residential land use of 400 mg/kg are present at locations JTP-1, JTP-2, JTP-3, JTP-9, JTP-14, and JTP-15 at depths of 1 to 3 feet below ground surface. These lead concentrations are associated with historic surficial fill and decrease sharply to background levels within the underlying native reddish brown clayey till. PAH concentrations exceed USEPA residential RSLs and typical urban background levels at locations JTP-2, JTP-4, and JTP-6 at depths of 1 to 3 feet below ground surface, with benzo(a)pyrene exceeding the USEPA residential RML at location JTP-4 within the 0-1 foot interval. Similar to lead, concentrations of PAHs are generally highest within the surficial historic fill layer at depths of 1-3 feet below ground surface and decrease to background levels within the underlying native reddish brown clayey till. Generally, soil concentrations of lead and PAHs exceed screening criteria sporadically throughout the parcel within the surficial historic fill layer to depths of 1 to 3 feet below ground surface. These results indicate that a removal action under CERCLA may be warranted to provide a long-term remedy and allow the property to be transferred. Based on an estimated surface area of 23,678 square feet across the parcel, and an average fill depth of 20 inches, 1,460 bank cubic yards of historic fill may be estimated across the parcel. Adding another foot across the parcel to address uncertainty in the estimate would add 876 bank cubic yards, for 2,336 bank cubic yards.

OFFICE OF
SOLID WASTE AND EMERGENCY RESPONSE

MEMORANDUM

SUBJECT: Transmittal of Guidance on Conducting Non-Time-Critical Removal Actions Under CERCLA (Publication 9360.0-32)

FROM: Henry L. Longest II, Director
Office of Emergency and Remedial Response

TO: Director, Waste Management Division
Regions I, IV, V, VII, VIII
Director, Emergency and Remedial Response Division
Region II
Director, Hazardous Waste Management Division
Regions III, VI, IX
Director, Hazardous Waste Division
Region X
Director, Environmental Services Division
Regions I, VI, VII
Superfund Branch Chiefs, Regions I-X
Regional Counsels, Regions I-X

PURPOSE

The purpose of this memorandum is to transmit new guidance on the appropriate use of non-time-critical removal authority under Superfund and the development of Engineering Evaluation/ Cost Analysis (EE/CA) reports and EE/CA Approval Memorandums. This guidance supersedes the March 30, 1988, outline from Timothy Fields, Jr. to the Superfund Branch Chiefs on the EE/CA process.

BACKGROUND

The National Oil and Hazardous Substances Pollution Contingency Plan (NCP) allows non-time-critical removal actions to be taken when there is a planning period of at least six months before on-site activities need to be initiated, and the lead agency determines that a removal action is appropriate (see 55 FR 8666, March 8, 1990). The most recent guidance on this subject was issued on March 30, 1988, when a draft outline of a EE/CA document was distributed for Regional review.

Printed on Recycled Paper

Despite clear authority to perform non-time-critical removal actions, few have been conducted. In order to encourage increased use of this type of response, we have developed this guidance to provide the Regional offices, as well as States and potentially responsible parties (PRPs), with the necessary information to conduct effective non-time-critical removal actions.

IMPLEMENTATION

Based on comments we have received while preparing this guidance, we expect that Regional offices will vary in implementing this guidance. A range of program staff may be called upon to conduct non-time-critical removal actions in the various Regions. We expect that the readers of this document will differ in their experience and training. Therefore, the guidance contains features that will be beneficial to readers coming from all perspectives, from EPA On-Scene Coordinators and Remedial Project Managers to State agency staff to members of the public. For example, the document contains thirteen bibliographic sections that identify sources of more detailed information, and numerous exhibits and diagrams. Readers who are unfamilar with the material presented in the guidance can therefore easily come up to speed with some additional reading, while readers already familiar with the process can simply focus on the significant material presented in the text.

So that the Regions may make maximum use of the information presented here, the guidance has been written to allow as much flexibility as possible, giving Regional managers the latitude to use information from various sources, make site-specific decisions, and take initiative on resolving problems. We have established a process called streamlined risk evaluation as an intermediate form of risk assessment unique to non-time-critical removal actions. There is also a side-by-side comparison of the EE/CA and remedial investigation/feasibility study (RI/FS) processes, to point out similarities and distinctions.

The information in this publication will assist Regional offices in accelerating selected responses in accordance with the Superfund Accelerated Cleanup Model (SACM). Bound copies of the guidance will be shipped directly to the Regional offices in eight to twelve weeks for distribution to Regional staff.

If you have any questions on this guidance, please contact Deborah Y. Dietrich at 703-603-8760.

CHAPTER 1

INTRODUCTION AND OVERVIEW

The purpose of this guidance is to provide information on the procedures and activities the U.S. Environmental Protection Agency (EPA) uses in conducting non-time-critical removal actions under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) and the National Oil and Hazardous Substances Pollution Contingency Plan (NCP). On-Scene Coordinators (OSCs) and Remedial Project Managers (RPMs) should use this guidance to ensure that non-time-critical removal actions are conducted in accordance with applicable laws, regulations, and EPA policy.

This guidance focuses primarily on those aspects of the removal process that are unique to non-time-critical removal actions. Introductory material presented in this chapter provides a context for how non-time-critical removal actions fit within the overall Superfund program.

Chapter 1 contains seven sections, as follows:

- Section 1.1 describes non-time-critical removal actions in relation to the Superfund Accelerated Cleanup Model (SACM).
- Section 1.2 provides an overview of the removal process.
- Section 1.3 highlights the roles and responsibilities of Federal, State, and private entities in conducting non-time-critical removal actions.
- Section 1.4 outlines the resources available to OSCs/RPMs in conducting non-time-critical removal actions.
- Section 1.5 describes enforcement and cost recovery activities.
- Section 1.6 highlights public involvement and administrative record requirements for non-time-critical removal actions.
- Section 1.7 describes Action Memorandum requirements for non-time-critical removal actions.

Chapter 2 provides guidance for conducting an Engineering Evaluation/Cost Analysis (EE/CA), which analyzes removal action alternatives for a site. Chapter 2 supersedes the outline for conducting an EE/CA dated March 30, 1988. An EE/CA, required under section 300.415(b)(4)(i) of the NCP for all non-time-critical removal actions, provides a vehicle for public involvement and evaluates and recommends the appropriate response.

Chapter 2 describes the following EE/CA activities:

- Section 2.1 provides information on when non-time-critical removal actions may be appropriate and on the EE/CA development process.

- Section 2.2 describes the purpose and content of the EE/CA Approval Memorandum.
- Section 2.3 explains that the Executive Summary should provide a general overview of the EE/CA.
- Section 2.4 highlights the types of information that should be gathered to characterize the site, determine the source, nature, and extent of contamination, and assess risks posed by the site.
- Section 2.5 outlines how to identify removal action objectives for the non-time-critical removal action.
- Section 2.6 describes the process for identifying and analyzing removal action alternatives.
- Section 2.7 describes how to compare removal action alternatives for effectiveness, implementability, and cost.
- Section 2.8 describes how to determine the recommended removal action alternative.

Details on conducting removal actions are found in a variety of laws, regulations, and guidance documents. Additional references that may be consulted for further information are presented at the conclusion of each section of this chapter, with a list of references presented in Appendix A of this guidance. Appendix B presents a key word index of major terms used in this guidance. Appendix C presents a comparison of the EE/CA process and the remedial investigation/feasibility study (RI/FS) process. Appendix D presents a model Notice of Decision Not to Use Special Notice Procedures.

1.1 THE SACM APPROACH

SACM is now being implemented to make Superfund cleanups more timely and efficient. The non-time-critical removal action represents a primary SACM tool for accomplishing early actions, and can be applied to a broad array of response actions. Specifically, SACM involves:

- A continuous process for assessing site-specific conditions and the need for action
- Cross-program coordination of response planning
- Prompt risk reduction through early action
- Appropriate cleanup of long-term environmental problems
- Early public notification and participation
- Early initiation of enforcement activities.

SACM should be considered for all Superfund activities, so long as implementation is consistent with requirements of the NCP and CERCLA. Overall Superfund program priorities remain the same: address the worst problems first, aggressively pursue enforcement, and involve the public during all stages of the work. The goals of SACM are being accomplished by focusing on the front end of the cleanup process and better integrating all Superfund program components.

1.1 THE SACM APPROACH (CONTINUED)

SACM encourages EPA Regions to explore new ways to use removal authorities under the NCP to achieve prompt risk reduction. An integrated removal and remedial site management strategy under SACM will most likely involve the increased use of non-time-critical removal authority to achieve prompt risk reduction at Superfund sites. Regional Decision Teams (RDTs), a SACM concept introduced in OSWER Publication 9203.1-05I, Volume I, Number 5, "SACM Regional Decisions—Interim Guidance" (December 1992), PB93-96266, are anticipated to emphasize early actions such as non-time-critical removal actions without jeopardizing the Superfund program's commitment to enforcement first. Decisions will be made to ensure that an early action will be consistent with any long-term action that may eventually be required. In the context of non-time-critical removal actions, this means that opportunities for treatment and permanence should be fully evaluated in the EE/CA, where appropriate (see Chapter 2).

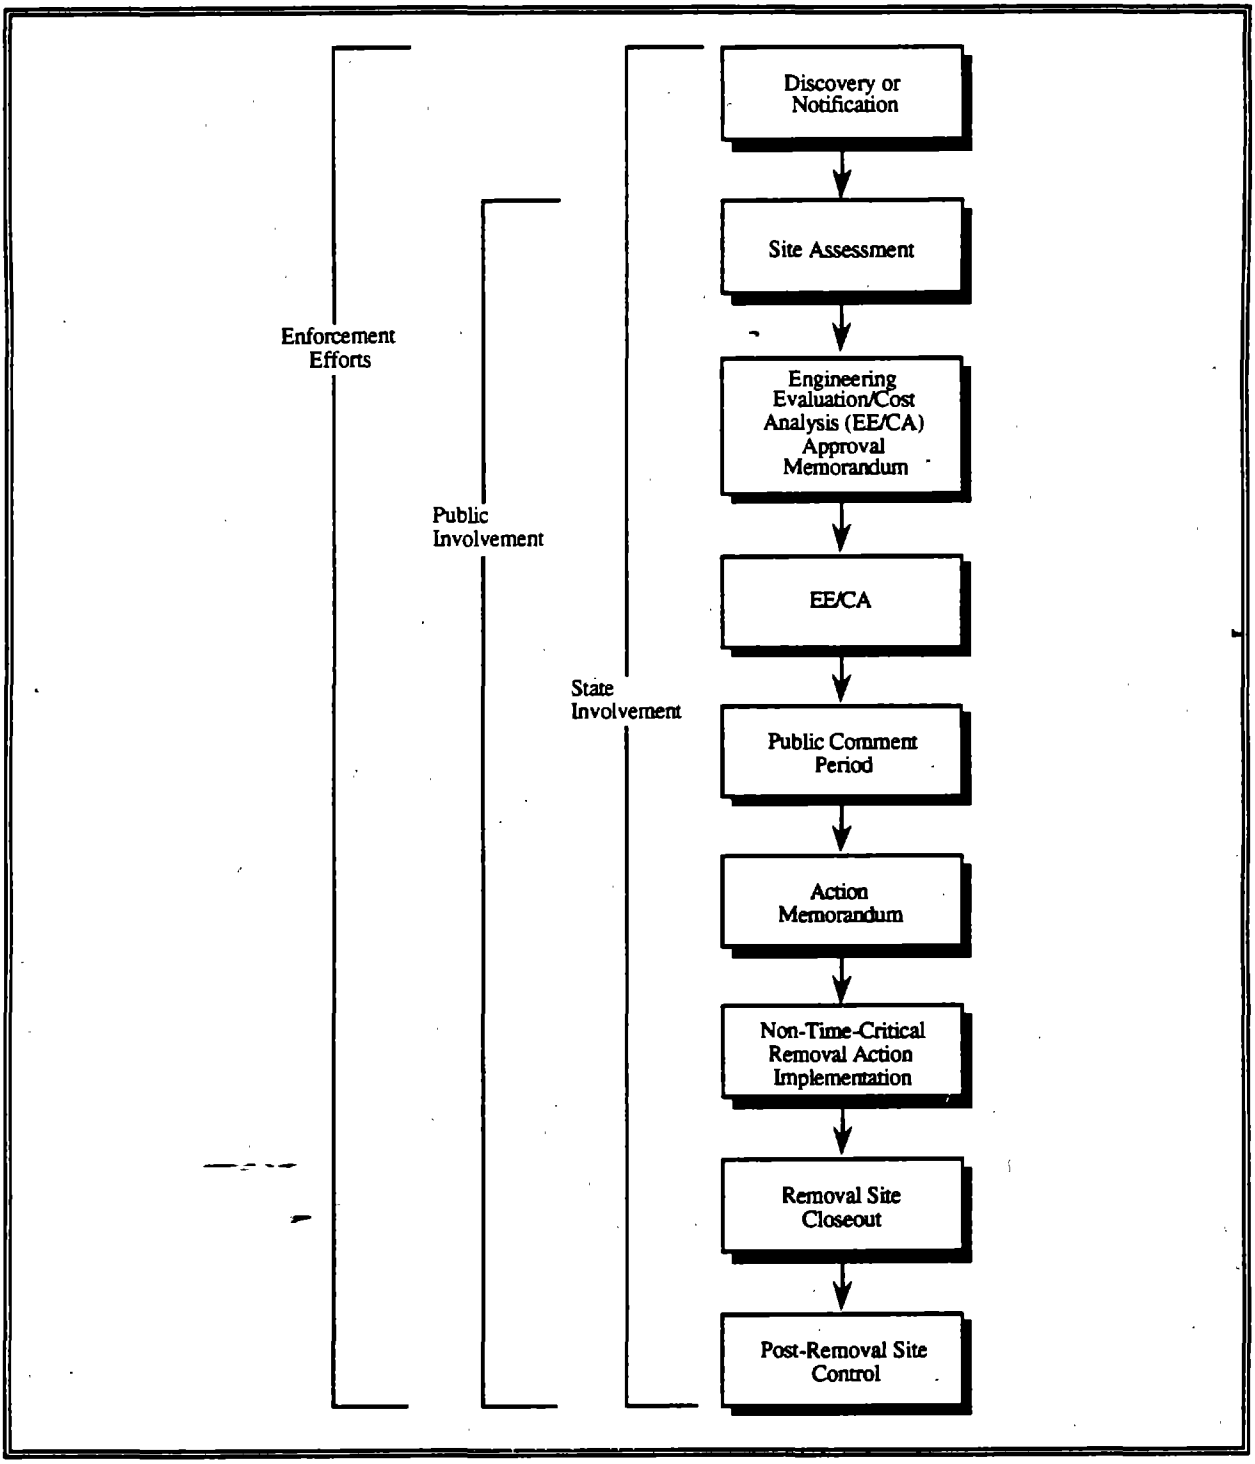
1.2 OVERVIEW OF THE REMOVAL ACTION PROCESS

CERCLA and the NCP define removal actions to include "the cleanup or removal of released hazardous substances from the environment, such actions as may necessarily be taken in the event of the threat of release of hazardous substances into the environment, such actions as may be necessary to monitor, assess, and evaluate the release or threat of release of hazardous substances, the disposal of removed material, or the taking of such other actions as may be necessary to prevent, minimize, or mitigate damage to the public health or welfare or to the environment, which may otherwise result from a release or threat of release." EPA has categorized removal actions in three ways: emergency, time-critical, and non-time-critical, based on the type of situation, the urgency and threat of the release or potential release, and the subsequent time frame in which the action must be initiated. Emergency and time-critical removal actions respond to releases requiring action within 6 months; non-time-critical removal actions respond to releases requiring action that can start later than 6 months after the determination that a response is

necessary. Each response is unique and may require more expedited response based on the threatened population, contaminants of concern, and other factors. The following are potential removal actions identified in section 300.415(b)(2)(i)-(viii) of the NCP:



- Prevention or abatement of actual or potential exposure to nearby human populations, animals, or the food chain from hazardous substances, pollutants, or contaminants
- Prevention or abatement of actual or potential contamination of drinking water supplies or sensitive ecosystems
- Stabilization or elimination of hazardous substances in drums, barrels, tanks, or other bulk storage containers that may pose a threat of release
- Treatment or elimination of high levels of hazardous substances, pollutants, or contaminants in soils largely at or near the surface that may migrate
- Minimization or elimination of the effects of weather conditions that may cause hazardous substances, pollutants, or contaminants to migrate or to be released
- Elimination of threat of fire or explosion
- Determination of availability of other appropriate Federal or State response mechanisms to respond to the release
- Mitigation or abatement of other situations or factors that may pose threats to public health, welfare, or the environment.

OSCs/RPMs must always consider section 300.415 in determining the appropriateness of taking any removal action. Section 300.415(d)(1)-(9) of the NCP provides a partial list of removal actions that may be taken to address specific situations. Exhibit 1, on the following page, illustrates the non-time-critical removal action process.

The following steps are for non-time-critical removal actions:

- Section 300.410 of the NCP outlines the process for conducting a **removal site evaluation**, which includes a removal preliminary assessment (PA) and, if warranted, a removal site inspection (SI). The OSC/RPM performs the removal PA, based on readily available information, to identify the source and nature of the release or threatened release and to assess the threat to public health, the magnitude of the threat, and the factors necessary to determine the need for a removal action. The removal PA also determines if more information is needed to characterize the release, such as off-site or on-site inspection of conditions and sampling. If more information is necessary, the OSC/RPM performs a removal SI. Data gathered during the removal site evaluation help OSCs/RPMs determine the need for response, if any, and the urgency of the response. For non-time-critical removal actions, OSCs/RPMs further characterize the release and propose the removal action as a result of the EE/CA process, as discussed in Chapter 2. The subsequent selection of the appropriate response is made in the Action Memorandum.

EXHIBIT 1
Non-Time-Critical Removal Action Process*

* Additional removal actions or remedial actions may occur at any time, depending on the exigencies of the site conditions.

1.2 OVERVIEW OF THE REMOVAL ACTION PROCESS (CONTINUED)

- In general, the **EE/CA Approval Memorandum** is prepared by the OSC/RPM once the removal site evaluation has been completed and the need for a non-time-critical removal action has been determined. This memorandum serves three important functions. First, the memorandum is used to secure management approval and funding to conduct the EE/CA. Second, it documents that the situation meets the NCP criteria for initiating a removal action and that the proposed action is non-time-critical. Third, it provides detailed information pertaining to the site background; threats to public health, welfare, or the environment posed by the site (e.g., expected changes in the situation if no action is taken or if the action is delayed); enforcement activities related to the site; and projected costs.

- An **EE/CA** must be completed for all non-time-critical removal actions as required by section 300.415(b)(4)(i) of the NCP. The goals of the EE/CA are to identify the objectives of the removal action and to analyze the various alternatives that may be used to satisfy these objectives for cost, effectiveness, and implementability. While an EE/CA is similar to the RI/FS conducted for remedial actions, it is less comprehensive. The Action Memorandum summarizes the EE/CA. EE/CAs are considered CERCLA section 104(b)(1) studies. Therefore, EE/CA costs are not counted toward the $2 million statutory limit on removal actions.

- A public notice describing the EE/CA (see Chapter 2) and announcing a **public comment period** must be published in a major local newspaper. The public notice may be combined with notice of the availability of the administrative record file, pursuant to the administrative record requirement in section 300.820 of the NCP. The EE/CA is part of the administrative record file and is subject to the public comment and comment response requirements for the administrative record.

1.3 ROLES AND RESPONSIBILITIES

Because of the urgency of emergency and time-critical removal actions, EPA OSCs/RPMs or U.S. Coast Guard OSCs generally retain the lead for conducting or overseeing these actions. For non-time-critical removal actions, it may be appropriate for the State to take the lead in conducting the removal action or taking enforcement actions. Regardless of who takes the lead, the OSC/RPM is responsible for determining whether technical assistance is needed from another agency and arranging for that assistance.

In carrying out a non-time-critical removal action, the OSC/RPM directs or reviews the work of other agencies, PRPs, and contractors to ensure compliance with CERCLA and the NCP; reviews all decision documents, enforcement orders, and workplans; oversees all expenditures of EPA funds; and ensures that all staff working on the response know site operating and safety procedures. The following section briefly describes the types of responsibilities specific to non-time-critical removal actions.

Regional Decision Team

The RDT convenes to consider response options at the point when assessment information is adequate to support decision-making. The RDT, a new concept under SACM, ensures effective coordination, communication, and integration of Superfund program authority, expertise, resources, and tools. For non-time-critical removal actions, the RDT should assist in assessing the

opportunity for response and in initiating the preparation of the EE/CA Approval Memorandum, the EE/CA, and the Action Memorandum. The RDT assists in determining whether proposed actions are time-critical or non-time-critical or whether the site requires remedial action. RDT involvement in emergency removal action and the more time-critical removal action decision-making may be limited based on the time available before initiating action. Also, RDT involvement in removal assessments and decision-making may vary from Region to Region.

State Involvement

Pursuant to 40 CFR Subpart O, section 35.6200, when a planning period of more than 6 months is available, States, political subdivisions, and Indian Tribes may apply for a removal Cooperative Agreement (CA) to lead a non-time-critical removal action. When a State does not participate in conducting and/or financially supporting a Fund-lead non-time-critical removal action, the RDT should first determine the urgency of the situation, and then, depending on the outcome of the urgency assessment, determine whether the non-time-critical removal action should proceed despite lack of State involvement. Headquarters will remain involved under SACM for approving consistency exemptions from the $2 million removal limit at sites not on the National Priorities List (NPL).

Potentially Responsible Party (PRP) Involvement

One of EPA's primary objectives for any Superfund action is to have the parties responsible for the release of hazardous substances be accountable for the response. CERCLA authorizes EPA to negotiate settlements, issue orders to compel response, or sue PRPs to repay response costs when the Fund has been used to finance removal actions. Because non-time-critical removal actions permit a planning period of at least 6 months, there is time for enforcement planning before the start of on-site activity. As with other removals, the OSC/RPM should work with Regional technical enforcement staff to identify PRPs, initiate actions to obtain PRP response, and conduct negotiations to enter into settlement agreements (see section 1.5).

Responsibility for Post-Removal Site Control (PRSC)

In some cases, PRSC activities will be necessary to ensure the continuing effectiveness of a completed non-time-critical removal action. Examples of these activities are relighting gas flares, replacing filters, and collecting leachate. Superfund program policy for completing removal actions states that protracted and costly long-term PRSC is more appropriately conducted by the affected State or local government or PRPs. If the OSC/RPM believes that PRSC may be necessary, the OSC/RPM should obtain a commitment from the State or local government or PRP to perform and fund necessary PRSC actions prior to initiating a response. Such commitments could be part of a settlement document with a PRP or take the form of a letter agreement or Memorandum of Understanding (MOU) with State or local governments. If the OSC/RPM is unable to obtain such an agreement, removal options that involve continuing PRSC should be avoided where other options are feasible.

1.3 ROLES AND RESPONSIBILITIES (CONTINUED)

7. OSWER Publication 9360.3-06, "Superfund Removal Procedures—Removal Enforcement Guidance for On-Scene Coordinators" (April 1992), PB92-963409.

1.4 RESOURCES

A number of resources can provide technical assistance to the lead agency carrying out a non-time-critical removal action. These include national, Regional, and specialized response teams; contractors; other Federal agencies; and State and local governments. Section 300.145 of the NCP describes special teams and other assistance available to OSCs/RPMs.

In addition, Superfund's Long-Term Contracting Strategy (LTCS) (OSWER Publication 9242.6-07, "Approval of Long-Term Contracting Strategy for Superfund [Superfund Management Review: Recommendations E.2]" [August 1990]), PB90-273822/CCE, provides OSCs/RPMs with mechanisms for greater flexibility in selecting contract support and improves oversight and cost management by giving the Regions full responsibility for contracts management. This strategy provides a road map to Superfund contractor support. The LTCS anticipated many of the underlying principles of SACM. For example, the increase in early action responses will be aided by the newly created Emergency and Rapid Response Services (ERRS) contracts. The LTCS also combines site assessment and removal technical assistance functions under single Superfund Technical Assessment and Response Team (START) contracts. The LTCS envisions that the Agency's non-time-critical removal actions will be performed using Response Action Contracts (RACs). Available contracting vehicles and capacities will affect the strategy for conducting both early and long-term actions under SACM. The process of developing these and other new contracts has begun and will continue over the next several years, consistent with the phase-in of SACM.

Currently, a variety of contractor resources is available to OSCs/RPMs. OSWER Publication 9200.5-402A, "Contracting and Subcontracting Guide to the Superfund Program" (May 1992), EPA/540/G-91/012, PR-923, lists available contractor firms in each Region and individuals to contact for information on available contracts.

1.5 ENFORCEMENT AND COST RECOVERY

PRP Search and Identification

EPA expects much of the early site assessment activities to be Fund-lead. However, changes to PRP-lead can occur during site assessment, prior to the EE/CA, or prior to initiating the non-time-critical removal action. The increased pace of response under SACM's integrated assessment process may require that the enforcement team work faster and devote more resources to PRP search and identification early in the process. This may lead to changes in PRP search methodology and, therefore, require less time to complete the PRP search than the current process.

Notice Letters

For time-critical and emergency removal actions, the time available to conduct enforcement activities will be limited, and notice letters will typically be issued simply to notify the PRP of its potential liability ~~or to~~ encourage informal negotiations. However, in many instances, formal negotiations may be more appropriate for non-time-critical removal actions. Regions may use CERCLA section 122(e) special notice letters for non-time-critical removal actions whenever practicable unless use of such procedures would interfere with the Agency's ability to implement a response in an expeditious manner. When deciding the appropriateness of using CERCLA section 122(e) special notice procedures, OSCs should consider whether viable PRPs have been identified, and whether identified PRPs are expected to respond favorably to the invitation to negotiate.

Issuance of the CERCLA section 122(e) special notice letter triggers a 60- to 120-day moratorium on on-site response activities under CERCLA section 104(a), including conducting the RI/FS. However, this does not mean that all activity related to the non-time-critical removal falls under the moratorium. Pursuant to section 122(e)(2)(A), the Agency may commence any

additional studies or investigations authorized under section 104(b) during the negotiation period. Since EE/CAs are considered CERCLA section 104(b) studies, preparation of the EE/CA may continue during the moratorium. Under this moratorium, if the PRP does not provide EPA with a good faith offer, the moratorium ends after 60 days.

Whenever EPA decides to forego use of CERCLA section 122(e) special notice procedures, CERCLA section 122(a) requires EPA to notify the PRP in writing of the reasons why formal negotiations are inappropriate. OSCs issuing such notice should refer to Appendix D, which presents a model Notice of Decision Not to Use Special Notice Procedures.

PRP Negotiation

Preparing certain documents before negotiations ensures that EPA will enter negotiations with a well-defined plan for PRP or agency response. One of the goals of negotiations is to develop an Administrative Order on Consent (AOC). The AOC may contain a workplan as an attachment. The AOC also might require the PRP to draft a detailed workplan as a first deliverable. AOCs should contain reimbursement provisions for past costs and oversight costs, where appropriate. If the initial removal assessment indicates that a non-time-critical removal action should be taken, the Region could negotiate an order with the PRPs for the EE/CA and include the eventual non-time-critical removal action in the order under CERCLA section 106 authority.

For non-time-critical removal actions, sufficient time is usually available to negotiate consent agreements with the PRP. However, if the PRP does not respond to notice letters or refuses to sign an AOC, EPA has the authority to proceed with a Fund-lead response or under CERCLA section 106, where an imminent and substantial endangerment exists, to issue a Unilateral Administrative Order (UAO) requiring a PRP to perform the removal action.

It is generally anticipated that by using SACM's phased PRP search approach, as described in OSWER Publication 9203.1-05I, Volume I, Number 3, "Enforcement Under SACM—Interim Guidance" (December 1992), PB93-963264, there will be sufficient time before initiating non-time-critical removal actions to allow those actions to be PRP-lead. For example, if the RDT decides, based on the early results of a PRP search, to initiate a Fund-lead EE/CA to support a non-time-critical removal action, the Region can continue PRP search activities during the EE/CA. After completing the EE/CA, the RDT can decide, based on supplemental PRP data, to seek PRP participation in conducting the non-time-critical removal action.

Cost Recovery

The statute of limitations for cost recovery for removal actions is 3 years from the completion of the removal action, unless a consistency exemption to the statutory limits under CERCLA section 104(c)(1)(C) has been approved. (In these circumstances, the statute of limitations is 6 years from the date of the last exemption.) A consistency exemption may be sought if the continued response action under CERCLA removal authorities is appropriate and consistent with the remedial action to be taken (see OSWER Publication 9360.0-12A, "Final Guidance on Implementation of the 'Consistency' Exemption to the Statutory Limits on Removal Actions" [June 12, 1989], PB90-274465/CCE). EPA's past costs should be sought in negotiations with PRPs, when appropriate. A decision not to pursue cost recovery must be documented in a Removal Action Cost Recovery Close-Out Memorandum prepared in consultation with the Office of Regional Counsel (ORC).

1.6 PUBLIC INVOLVEMENT AND THE ADMINISTRATIVE RECORD

As with all CERCLA actions, early and frequent involvement of the public, including involvement above and beyond the requirements, is crucial to expedited cleanups under SACM.

1.6 PUBLIC INVOLVEMENT AND THE ADMINISTRATIVE RECORD (CONTINUED)

Public involvement activities in Superfund promote communication between members of the public, including PRPs, and the lead government agency responsible for removal or remedial actions. Public involvement activities should be tailored to the needs of the community as well as to the technical action schedule.

Section 113(k)(2) of CERCLA provides for involving communities affected by response decisions at Superfund sites. Public involvement in the Superfund program, as a whole, consists of public outreach activities conducted throughout the planning and implementation of Superfund removal and remedial responses.

Since removal actions generally proceed quickly, there is less time to plan or conduct public participation activities than during remedial responses. Sections 300.415(m) and 300.820 of the NCP specify two forms of public participation for all removal actions:

- Community relations activities--designed to integrate the information needs of the community into the communications approach or community relations plan for the site.

- Administrative record activities—designed to chronicle the basis for the response selection and serve as a vehicle for public participation in the removal action.

Community Relations Requirements

The NCP and CERCLA outline a variety of community relations requirements to promote communication. The following are requirements for non-time-critical removal actions:

- Designate Community Relations Spokesperson. This person shall inform the community of actions taken, respond to inquiries, and provide information concerning the release.

- Conduct Community Interviews. Before completing the EE/CA, the lead agency must conduct community interviews to gather background information for the Community Relations Plan (CRP). The purpose of these interviews is to solicit information about community concerns, information needs, and how or when citizens would like to be involved in the removal action.

- Prepare CRP. Pursuant to sections 300.415(m)(4), 300.415(m)(4)(i), and 300.415(m)(3)(ii) of the NCP, a CRP must be prepared before the EE/CA is completed. The CRP is a site-specific document that relates the community relations techniques and approaches deemed appropriate and relevant to the site.

- Establish Information Repository. The information repository must be established no later than the signing of the EE/CA Approval Memorandum (see Chapter 2). The repository is a project file or collection of materials relating to the specific Superfund site and to the Superfund program in general. The administrative record file is included in the repository.

- Provide Public Notice of Availability of EE/CA. A public notice describing the Agency's preferred alternative and EE/CA results (see Chapter 2) and announcing

its availability for review and comment must be published in a major local newspaper. The EE/CA is part of the administrative record file.

Administrative Record Requirements

The administrative record file, a subset of the site file, is the body of documents EPA uses to form the basis for the selection of a response. It should not be confused with the administrative record, which is not complete until a response action has been selected. The administrative record file, as provided in section 300.820 of the NCP, may include site-specific data and comments, documents which were considered or relied on to select the removal action, guidance documents, technical references, and documents that reflect the views of the public, including PRPs, concerning the selection of a removal action. A strong administrative record helps ensure cost recovery, helps uphold EPA's remedy selection, and helps limit litigation-related information gathering discovery. For non-time-critical removal actions, the EE/CA Approval Memorandum, the EE/CA, and the Action Memorandum are critical components of the administrative record file. The administrative record closes once the decision document, in the case of a non-time-critical removal action the Action Memorandum, is signed. The record will reopen if the Action Memorandum is amended. The required administrative record activities for non-time-critical removal actions are:

- Establish the Administrative Record File. The administrative record file must be established no later than the signing of the EE/CA Approval Memorandum. The OSC/RPM, as the lead for on-site activity, is responsible for compiling and maintaining the administrative record in accordance with the NCP. The administrative record file must be made available for public inspection and copying when the EE/CA is made available for public comment at a central location at or near the site.

- Publish Notice of Availability of the Administrative Record File. A public notice must be published when the EE/CA is placed in the administrative record file and is available for comment. Additionally, if the notice also is used to announce a public comment period on the EE/CA, then it must state that upon timely receipt of a request (defined in the NCP preamble as generally within 2 weeks after the public comment period starts, but it may be considered valid if received within the 30-day period), the comment period will be extended a minimum of 15 additional days.

- Hold Public Comment Period. For non-time-critical removal actions, the NCP requires a 30-day public comment period on the EE/CA and any supporting documentation (including fact sheets or other documents summarizing the alternatives under consideration) at the time the EE/CA is made available for public comment.

- Develop Written Response to Significant Comments. After the public comment period is over, the OSC/RPM is required to prepare a written response to significant comments received during the comment period. The response to comments should be included in the administrative record file.

1.7 ACTION MEMORANDUM

An Action Memorandum provides a concise, written record of the decision to select an appropriate removal action. Exhibit 2, on the following page, provides an outline of the information that should be included in the Action Memorandum. As the primary decision document, it substantiates the need for a removal action, identifies the proposed action, and explains the rationale for the removal action selection. In this respect, the Action Memorandum for removal actions parallels the function of the Record of Decision (ROD), which documents the final action plan for a remedial response; however, the Action Memorandum is not as elaborate as the ROD. An Action Memorandum may also reserve the appropriate funding needed for the proposed removal action.

Action Memoranda follow a standard format. Specific topics must be addressed in the Action Memorandum to demonstrate that the release meets statutory and NCP requirements for a removal action. For non-time-critical removal actions, an EE/CA summary or the EE/CA Executive Summary, the EE/CA Approval Memorandum or a summary thereof, and a summary of the written comments on the EE/CA for alternative actions considered for non-time critical removal actions should be part of the "Proposed Actions and Estimated Costs" section of the Action Memorandum. In addition, a copy of the EE/CA, or the Executive Summary, and the Agency's response to significant public comments on the EE/CA should be attachments to the Action Memorandum and become part of the administrative record file.

1.8 ON-SCENE COORDINATOR REPORTS

As currently stated in section 300.165 of the NCP, within 1 year after completion of removal activities involving a major release, or when requested by the Regional Response Team (RRT), the OSC/RPM must submit to the RRT a complete report on the removal operation and the actions taken. A copy of the report must also be sent to the Secretary of the National Response Team (NRT). The report shall record the situation as it developed, the actions taken, the resources committed, and the problems encountered.

There is an established format for OSC reports set out in section 300.165 of the NCP. The report must contain the following:

- Summary of Events—a chronological narrative of all events, including:
  - Location of the hazardous substance
  - Cause of the discharge or release
  - Initial situation
  - Efforts to obtain response by responsible parties
  - Organization of the response, including State participation
  - Resources committed
  - Content and time of notice to natural resources trustees
  - Federal or State trustee damage assessment activities and efforts to replace or restore damaged natural resources
  - Details of any threat abatement action taken
  - Treatment/disposal/alternative technology approaches pursued and followed
  - Public information/community relations activities.
- Effectiveness of removal actions taken by:
  - Responsible party(ies)
  - State and local entities
  - Federal agencies and special teams
  - Contractors, private groups, and volunteers (if applicable).
- Difficulties encountered—a list of items that affected the response, with particular attention to issues of intergovernmental coordination.

1.8 ON-SCENE COORDINATOR REPORTS (CONTINUED)

- Recommendations, including:
  - Means to prevent a recurrence of the discharge or release
  - Improvement of response actions
  - Recommended changes in the NCP, regional contingency plan, area contingency plan, OSC contingency plan or other local emergency response plans.

CHAPTER 2

CONDUCTING THE ENGINEERING EVALUATION/COST ANALYSIS (EE/CA)

2.1 OVERVIEW

In 1987, the Emergency Response Division began development of the first draft guidance on Engineering Evaluations/Cost Analyses (EE/CAs) for non-time-critical removal actions. Because issuance of a final EE/CA guidance was delayed pending the outcome of issues related to the NCP revisions, in 1988 a draft outline was distributed to assist the Regions in preparing EE/CAs. This chapter replaces the 1988 memo to help the Regions in fulfilling the goals of the EE/CA, which are to:

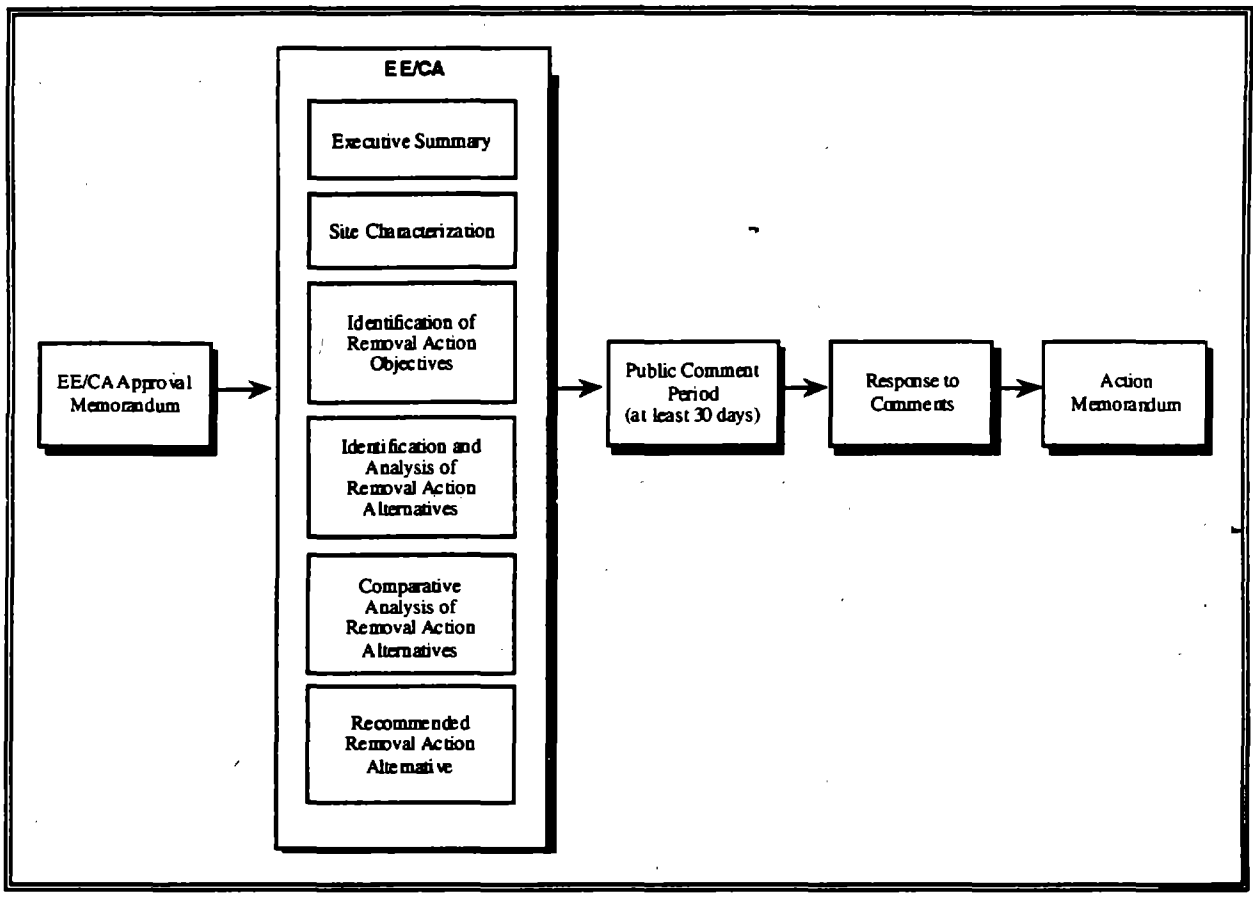
- Satisfy environmental review requirements for removal actions
- Satisfy administrative record requirements for improved documentation of removal action selection
- Provide a framework for evaluating and selecting alternative technologies.

Non-time-critical removal actions will be the appropriate response for a variety of sites and will range in scope from small-scale, low-cost actions to complicated multi-media response actions requiring exemptions from the statutory time and/or dollar limits. Non-time-critical removal actions may be interim or final actions; they may be the first and only action at a site, or one of a series of planned response actions. The scope of the non-time-critical removal action will determine the detail of the EE/CA. The EE/CA is a flexible document tailored to the scope, goals, and objectives of the non-time-critical removal action. It should contain only those data necessary to support the selection of a response alternative, and rely upon existing documentation whenever possible.

The range of site characteristics affecting the non-time-critical removal action forms a continuum. At one end are sites where the non-time-critical removal action is the first and only action expected at a site and where no other data are available. In this case, the EE/CA should provide definitive information on the source, nature, and extent of contamination, and risks presented by the site. At the other end of the continuum are sites where the non-time-critical removal action is one of a series of response actions, where a completed RI is or will be available, and where the nature and extent of contamination and the risk presented by the site have been or will be determined. In this case, the EE/CA would be similar to a focused FS, concentrating on the analysis of perhaps two or three appropriate alternatives and providing reference to existing information on the nature and extent of contamination and risks.

Many non-time-critical removal actions may occur at sites with characteristics that fall within these extremes. OSCs/RPMs should tailor the EE/CA to match the specific goals and objectives of the non-time-critical removal action planned for a given site. The goals of the removal should be based on the relevant factor(s) listed in sections 300.415(b)(2)(i)-(viii) of the NCP. The relevant factors should be cited in the EE/CA Approval Memorandum as justification for conducting the EE/CA. The scope of the action takes into account two major considerations: the physical portion of the site to be addressed and whether the action represents a final or interim step toward addressing a particular exposure pathway.

2.1 OVERVIEW (CONTINUED)



Specific objectives are then developed for the site. Removal action objectives generally consist of environmental medium-specific goals for protecting human health and the environment. The objectives should be as specific as possible, but not so specific that the range of alternatives that can be developed is unduly limited. Removal action objectives should identify, for example, the contaminants of concern and exposure route(s) and receptor(s).

The scope of the non-time-critical removal action (e.g., an interim action conducted during an ongoing remedial effort) and the specific objectives determine the information to be collected during the EE/CA. Accordingly, qualitative risk information that identifies pathways of concern and concentrations of contaminants above standards could have been documented at the site during the RI, and may be referred to in the EE/CA; a separate risk assessment is not necessary to support the non-time-critical removal action. Data to characterize the nature and extent of contamination should be limited to those needed to support the specific objectives of the non-time-critical removal action, supplementing existing data (e.g., the existing RI/FS) to the extent appropriate. Finally, an initial screening of alternatives generally will not be necessary; only a few viable alternatives relevant to the EE/CA objectives should be identified and analyzed.

As noted in Chapter 1, an EE/CA must be completed for all non-time-critical removal actions under CERCLA as required by section 300.415(b)(4)(i) of the NCP. The goals of the EE/CA are to identify the objectives of the removal action and to analyze the effectiveness, implementability, and cost of various alternatives that may satisfy these objectives. Thus, an EE/CA serves an analogous function, but is more streamlined than the RI/FS conducted for remedial actions. Soliciting and responding to public comments on the administrative record, including the EE/CA, is required by section 300.820(a) of the NCP. (See Appendix C for a side-by-side comparison of the EE/CA process and the RI/FS process.)

The results of the EE/CA, along with EPA's response decision, are summarized in the Action Memorandum. The costs of performing an EE/CA, which is considered a CERCLA section 104(b)(1) study, are not counted toward the $2 million statutory limit on removal actions. Exhibit 3, on the following page, depicts the process for developing an EE/CA.

EXHIBIT 3
EE/CA Development Process

This chapter provides guidance on the components of the EE/CA Approval Memorandum, as shown in Exhibit 4, on the following page, and the EE/CA, as shown in Exhibit 5. The chapter discusses and provides checklists for each section of the EE/CA; however, each section can be modified to satisfy special requirements of the removal action or to justify the selection of a specific alternative.

   §300.415(b)(4)(i), EE/CA Requirement

2.1 OVERVIEW (CONTINUED)

EXHIBIT 4
EE/CA Approval Memorandum

- ❑ Subject
- ❑ Background
- ❑ Threat to Public Health, Welfare, or the Environment (Includes Expected Change If No Action Taken)
- ❑ Imminent and Substantial Endangerment If Present
- ❑ Enforcement Actions
- ❑ Proposed Project/Oversight and Cost
- ❑ Approval/Disapproval

2.2 EE/CA APPROVAL MEMORANDUM

In general, the EE/CA Approval Memorandum is prepared once the need for a non-time-critical removal action has been determined; a removal site evaluation may have been completed, or if the site is on the NPL, information may also be available from other sources. The EE/CA Approval Memorandum is not a part of the EE/CA, but is part of the administrative record for the site.

The EE/CA Approval Memorandum serves important functions. First, it secures management approval and funding approval to conduct the EE/CA or, for PRP-lead actions, to provide oversight of EE/CAs. If the action is PRP-lead, provisions for oversight funding will be contained in an administrative order and should be included in an Approval Memorandum. Second, the memorandum documents that the situation meets the NCP criteria for initiating a removal action and that the required action is non-time-critical. Third, it provides a finding of an actual or threatened release from the site and, if present, a finding of an imminent and substantial endangerment, or refers to a document establishing such a determination. The Approval Memorandum also provides general information pertaining to the site background; threats to public health, welfare, or the environment posed by the site (including expected changes in the site situation if no action is taken or if the action is delayed); enforcement activities related to the site; and estimated EE/CA costs.

The EE/CA Approval Memorandum should indicate a current or potential threat to public health, welfare, or the environment. The memorandum should focus on providing sufficient information that such a threat or potential threat could exist, while the EE/CA will provide the information for EPA to determine that such a threat or potential threat actually exists. The preliminary identification of exposures is based on information obtained from the PA or SI and possibly other previous investigations. The OSC/RPM should develop a conceptual site model as a starting point for this analysis. The model identifies potential releases, potential areas of contamination, chemicals of concern, possible routes of exposure, possible routes of contaminant transport, and potential exposure pathways.

This potential for exposure indicates the likelihood of meeting the NCP criteria for taking a removal action, which in turn justifies the need for conducting the EE/CA. For example, risk consideration can identify the possibility of exposure of nearby populations, animals, or the food chain to hazardous substances, pollutants, or contaminants. Similarly, this preliminary risk

2.2 EE/CA APPROVAL MEMORANDUM (CONTINUED)

information may also indicate the possibility of contamination of drinking water or sensitive environments or other situations or factors that may pose threats to public health, welfare, or the environment.

The Regional Administrator (or authorized designee) evaluates the EE/CA Approval Memorandum and provides authorization. Funds expended to prepare an EE/CA Approval Memorandum are CERCLA 104(b)(1) monies and are not counted toward the $2 million statutory limit for removal actions.

  - ❑ Effectiveness
  - ❑ Implementability
  - ❑ Cost
- ❑ Comparative Analysis of Removal Action Alternatives
- ❑ Recommended Removal Action Alternative

2.3 EE/CA EXECUTIVE SUMMARY

The EE/CA Executive Summary provides a general overview of the contents of the EE/CA. It should contain a brief discussion of the site and the current or potential threat posed by site

2.3 EE/CA EXECUTIVE SUMMARY (CONTINUED)

conditions. The Executive Summary should also identify the scope and objectives of the removal action, as well as the removal action alternatives. Finally, this section of the EE/CA should provide information on the recommended removal action alternative.

The Executive Summary is intended to make the contents of the EE/CA more accessible to review by the public, and is analogous in this respect to the Proposed Plan used in the remedial process. This summary can then be used in the Action Memorandum, which should include a description of the EE/CA.

2.4 SITE CHARACTERIZATION

The EE/CA should summarize available data on the physical, demographic, and other characteristics of the site and surrounding areas. These data may be available from a removal site evaluation, from previous investigations, or from other EPA activities at the site (e.g., work in preparation for NPL listing). Documents providing information for the EE/CA should be placed in the administrative record for the site. Whatever the source, the data on the site must provide background engineering information for analysis of removal alternatives. Because of the CERCLA preference for treatment over containment or land disposal, it is important that alternatives that employ treatment and that yield permanent solutions be fully evaluated for non-time-critical removal actions and early remedial actions. Furthermore, potential differences between early action and long-term action data quality objectives and risk assessment goals should be reconciled as early as possible. Therefore, EPA should coordinate activities of the OSC/RPM with those of the site assessment manager, risk assessor, and enforcement/legal staff to ensure appropriate data are collected to characterize the site.

Information about the site may be readily available from many sources, including:

- Scoring packages for NPL sites
- Removal site evaluations
- Remedial PA/SI reports
- EE/CA Approval Memoranda
- RI/FSs
- RODs
- State and local government reports
- The Agency for Toxic Substances and Disease Registry (ATSDR) or State public health agencies
- State Historic Preservation Officer
- Environmental Impact Statements (EISs)
- CERCLA section 104(e) information requests
- Newspaper articles
- Resource Conservation and Recovery Act (RCRA) enforcement actions
- Published engineering evaluations and technical reference documents
- Documents from other Federal agencies, such as U.S. Geological Survey (USGS) maps and Federal Emergency Management Agency evacuation reports
- Company records
- Employee interviews
- EPCRA—Toxic Release Inventory data.

2.4 SITE CHARACTERIZATION (CONTINUED)

Site Description and Background

The site description includes current and historical information. This information may help identify hazardous substances, pollutants, or contaminants of concern, or areas of the site requiring additional sampling. In gathering this information, OSCs/RPMs should review State, local, and Federal permit files, construction records, and local deed records for information on previous owners to determine materials produced, stored, or disposed of at the site. CERCLA section 104(e) information requests should also be considered. In addition, interviews should be conducted, as necessary, with neighbors of the site or past employees who can describe past operational practices or identify other past employees. The site background may include historical and aerial photographs. The EE/CA should document these data to convey a clear understanding of the nature of the site.

The site description section of the EE/CA should include the following types of information where available and as appropriate to the site-specific conditions and the scope of the removal action:

- Site location
  - Street address and crossroads
  - USGS topographic map quadrangle
  - Latitude/longitude
- Type of facility and operational status
  - Materials manufactured, stored, or disposed on-site
  - Estimated quantities of contaminants and potential hazards
  - Years of operation
  - Present/prior site use
  - Regulatory history, including previous responses, investigations, and litigation by State, local, and Federal agencies
- Structures/topography
  - Facility size/dimensions
  - Boundary descriptions
  - Land cover/vegetation/stresses to topography
  - Utilities/transportation features
  - Buildings
  - Surface water bodies/conveyances
  - Drainage channels/pathways
  - Historically/archaeologically significant features
  - Sewer lines/manholes
  - Stormwater drainage pipes
  - Open ditches/canals
  - Power lines/pipelines
- Geology/soil information
  - Depth to aquifer
  - Soil types (surface and vadose zones)
  - Local geological formulations
  - Surface water hydrology and hydrogeology

2.4 SITE CHARACTERIZATION (CONTINUED)

- Surrounding land use and populations
  - Residential, industrial, or commercial land use
  - Possible pathways of exposure
  - Identification of sensitive populations
  - Estimate of population densities within potentially affected radius
  - Description of drinking water sources
  - National Historic Preservation Act considerations

- Sensitive ecosystems
  - Wetlands, wildlife breeding areas
  - Wild and scenic rivers
  - Connection to the human food chain or food chains of other organisms
  - Sensitive and/or endangered species
  - Coastal zones

- Meteorology
  - Rainfall/snowfall
  - Temperature ranges
  - Wind conditions

Previous Removal Actions

The site characterization section of the EE/CA should also describe any previous removal actions at the site. Exhibit 6, on the following page, shows useful information that may be obtained from a previous removal action and its applicability to the current EE/CA. Previous information, if relevant, may be organized as follows:

- The scope and objectives of the previous removal action
- The amount of time spent on the previous removal action
- The amount of money spent on the previous removal action
- The nature and extent of hazardous substances, pollutants, or contaminants treated or controlled during the previous removal action
- The technologies used and/or treatment levels used for the previous removal action.

Like all documents that serve as the basis for Superfund decisions, EE/CAs are subject to public review and must be part of the administrative record. Although confidential and enforcement-sensitive documents are typically not relied upon in selecting response actions, when they are relied upon they should be contained in a separate confidential portion of both the EE/CA and the administrative record. Confidential information includes the following:

- Trade secrets, commercial or financial information
- State secrets
- Confidential informant files
- Privacy Act privileged information, attorney-client privileged information, and attorney work product privileged information
- Information exempted by other statutes.

Enforcement-sensitive information that generally should not be placed in the administrative record file includes:

- Financial status of PRPs
- Record of previous negotiations with PRPs and the results
- Investigatory files relating to law enforcement
- Additional information on enforcement history, strategy, discussion, and recommendations.

EXHIBIT 6
Information From Previous Removal Actions Applicable To Current EE/CA

Information From Previous Removals	Applicability To Current EE/CA
Nature and Extent of Contaminants	This information may allow the OSC/RPM to narrow the scope of evaluation to certain areas of the site or to specific analyses.
Treatability of Compounds	Previous use of a technology may affect the decision to use the same technology again.
Equipment/Utilities at Site	If the previous removal action resulted in supplies and equipment being left at the site or provision of specific utilities (e.g., electrical power, sewer line), this information may affect the choice of treatment/control options employed.
Site-Specific Conditions	Lessons learned from a previous removal action are valuable to the current EE/CA. Specific examples could include seasonal weather patterns affecting technology applications or site access limitations because of vehicle transportation routes.

Source, Nature, and Extent of Contamination

To the extent possible, site characterization data should be gathered during the removal site evaluation to support the EE/CA, unless such data were gathered in prior investigations. Existing information may be useful in determining the location(s) of contamination at a particular site. This information may include:

- Location(s) of the hazardous substance(s), pollutant(s), or contaminant(s)
- Quantity, volume, size, or magnitude of the contamination
- Physical and chemical attribute(s) of the hazardous substance(s), pollutant(s), or contaminant(s)
- Target(s) potentially affected by the site.

2.4 SITE CHARACTERIZATION (CONTINUED)

The source of the contamination for a removal action is often well defined. However, if the source, nature, and extent of contamination cannot be readily identified, the OSC/RPM should survey the area. Contamination sources and locations can often be determined by:

- Using nonanalytical methods, including geophysical surveys, which may indicate the presence of buried objects, such as drums
- Examining aerial photographs (especially those taken over a period of time), which may indicate land areas or drainage patterns that have been disturbed
- Reviewing past operations and information from the Toxic Release Inventory and interviewing past or current employees, which may help determine the source of contamination.

If contamination is found in a containment vessel (e.g., under- or above-ground storage tanks, drums, lagoons), the integrity of the vessels should be determined. The integrity may have an impact on the selection of the removal action.

Analytical Data

The analytical data section presents quantifiable data collected for the EE/CA. This section begins with existing data and expands as additional data are collected. When sufficient data are collected, significant findings should be presented in a narrative discussion. The actual data can be presented in tables, either within the section or in an appendix, or incorporated by reference to the document containing the data.

Sampling should typically be performed in accordance with accepted EPA and Contract Laboratory Program (CLP) protocols. Where feasible, sampling should be coordinated through the integrated assessment approach of SACM. Where a SACM approach is used, appropriate data quality objectives should be used for decisions in support of remedial and removal actions. If the site is not already on the NPL, sample collection and analysis should generally ensure that data generated will also support assessment of whether NPL listing and remedial action are appropriate.

Analytical data from studies conducted by EPA or other groups (e.g., State or local health or environmental authorities or PRPs) are useful in characterizing the site. Reviewing any soil, water, or waste analyses will help OSCs/RPMs determine the precision, accuracy, representativeness, completeness, and comparability of previous sampling. These parameters can be evaluated by examining the results of routine quality control procedures, such as replicate samples and/or analyses, replicate spiked samples and/or analyses, field blanks, method blanks, and analysis of standard reference materials.

To reflect SACM's integrated assessment approach, future guidance will further address data collection and analysis to support removal actions, early remedial actions, and long-term actions. The Environmental Response Team (ERT) is currently developing integrated guidance on air, waste, and water sampling, and ecological assessment. All data used to justify a non-time-critical action should be supported by quality control data. Furthermore, these data should be

evaluated based on quality assurance documentation. Following this quality assurance and control process, data can be compared to existing health- or risk-based standards to determine the nature of the threat to public health, welfare, or the environment.

Streamlined Risk Evaluation

The streamlined risk evaluation is a new type of evaluation, intermediate in scope between the limited risk evaluation undertaken for emergency removal actions and the conventional baseline assessment normally conducted for remedial actions. This streamlined risk evaluation can help justify taking a removal action and identify what current or potential exposures should be prevented. The risk evaluation uses sampling data from the site to identify the chemicals of concern, provides an estimate of how and to what extent people might be exposed to these chemicals, and provides an assessment of the health effects associated with these chemicals. A streamlined risk evaluation projects the potential risk of health problems occurring if no cleanup action is taken at a site. Therefore, the results of the streamlined risk evaluation help EPA decide whether to take a cleanup action at the site, what exposures need to be addressed by the action, and in some cases define appropriate cleanup levels.

In planning a non-time-critical removal action, OSCs/RPMs should consult with the Regional risk assessors on potential action and cleanup levels. The risk evaluation at the site should remain the responsibility of EPA. Since removal and remedial action cleanup levels may differ, all early action decisions should consider the possible long-term action and corresponding cleanup levels. The OSC/RPM should ensure that all risk assessment activities are consistent with any future remedial action remaining to be taken (or potential for listing, if the site is not on the NPL) to achieve consistent risk goals. OSCs/RPMs should refer to OSWER Publication 9285.7-01B, "Risk Assessment Guidance for Superfund, Volume 1: Human Health Evaluation Manual, Part A, Interim Final" (December 1989), EPA/540/1-89/002, PB90-155581, for guidance on conducting risk evaluations.

For the EE/CA, the streamlined risk evaluation should focus on the specific problem that the removal action is intended to address. For example, if the non-time-critical removal action is to install a ground water containment system, the risk evaluation should address risk due to consumption and use of ground water. If the action is intended to address a particular source of contamination, the risk evaluation should address the risks related only to that source of contamination.

To assist in focusing the risk evaluation on specific site problems, OSCs/RPMs should rely on the conceptual site model and data developed during site characterization. A risk evaluation that identifies only contaminants of concern in the affected media, contaminant concentrations, and the toxicity associated with the chemical can be sufficient to justify taking an action. In some situations, exposure pathways can be identified as an obvious threat to human health or the environment by comparing EE/CA contaminant concentrations to standards that are potential chemical-specific applicable or relevant and appropriate requirements (ARARs) for the action. These may include non-zero Maximum Contaminant Level Goals (MCLGs) and Maximum Contaminant Levels (MCLs) for ground water or leachate, or State air quality standards for contaminants that may volatilize or be entrained by the wind. When potential ARARs for chemicals of concern do not exist for a specific contaminant, risk-based chemical concentrations should be used.

2.4 SITE CHARACTERIZATION (CONTINUED)

Where standards for one or more contaminants in a given medium are clearly exceeded, a removal action is generally warranted, and further quantitative assessment that considers all chemicals, their potential additive effects, or additivity of multiple exposure pathways, are generally not necessary. In cases where standards are not clearly exceeded, or where the available information is deficient or of questionable quality, a more thorough risk assessment may be advisable before deciding whether to take a removal action.

In most, if not all, PRP-and State-lead actions with no RI/FS or other site evaluation and little likelihood of future EPA remedial action, a conventional risk assessment will be necessary to evaluate all potential pathways. If more substantial information or data are needed regarding risks posed at a site (e.g., due to insufficient data quality from prior site work), OSCs/RPMs should not hesitate to request supplementary risk information before any type of response action is selected, being careful to justify any additional work that may be required. However, only in the case where the non-time-critical action will be the only Fund-lead action expected at the site should OSCs/RPMs consider performing a risk assessment that addresses all potential exposure pathways.

2.5 IDENTIFICATION OF REMOVAL ACTION SCOPE, GOALS, AND OBJECTIVES

Identifying the scope, goals, and objectives for a removal action is a critical step in the EE/CA and in the conduct of non-time-critical removal actions. At any release, regardless of whether the site is on the NPL, where the lead agency determines there is a threat to public health, welfare, or the environment, a removal action may be taken to abate, prevent, minimize, stabilize, mitigate, or eliminate the release or threat of release.

The following example illustrates this process at an NPL site with an ongoing RI/FS, and where an opportunity exists to conduct a non-time-critical removal action. The non-time-critical removal action will minimize migration of contaminated ground water and contaminants from subsurface soil but is considered an interim action because it is expected that the remedial action will ultimately address the area of concern.

In this example, the goal of the non-time-critical removal action is to minimize migration of contaminated ground water and to begin to reduce contaminants in the soil that are the source of ground water contamination. This goal corresponds to section 300.415(b)(2)(iv) of the NCP, which identifies "high levels of hazardous substances, pollutants, or contaminants in soils largely at or near the surface, that may migrate" as a factor to be considered in determining the appropriateness of a removal action.

Five specific objectives are then developed for the site:

- Minimize migration of contaminated ground water through installation of a containment system
- Initiate removal of volatile organic compounds from contaminated soils through in-situ treatment
- Dewater areas necessary to treat effectively the decontaminated soils
- Install and operate appropriate treatment systems for ground water and vapor generated by containment, dewatering, and soil treatment that will prevent unacceptable discharges or emissions.
- Dispose of waste streams from the removal action.

These objectives should be achieved by meeting specified cleanup levels while working within the statutory limits and attaining ARARs to the extent practicable. Exhibit 7 provides a checklist of factors to consider in developing EE/CA objectives.

Statutory Limits on Removal Actions

Because the EE/CA is a public document and readers may not be aware of the statutory limits on removal actions, the objectives section of the EE/CA should briefly explain the $2 million and 12-month statutory limits for Fund-financed removal actions pursuant to section 104(c)(1) of CERCLA. If the need for an exemption is determined early in the action, the details should be described in the EE/CA as well as in the Action Memorandum requesting the exemption.

2.5 IDENTIFICATION OF REMOVAL ACTION SCOPE, GOALS, AND OBJECTIVES (CONTINUED)

Determination of Removal Scope

The EE/CA should help define the scope of the removal action. The scope of the action could be, for example, total site cleanup, site stabilization, or surface cleanup of hazardous substances. It is critical that removal actions at non-NPL sites consider the potential for future listing to ensure the goals of the removal are consistent with any potential long-term remediation. When a non-time-critical removal action will be the only or last action taken to clean up a potential NPL site, the EE/CA should provide adequate documentation that activities performed at the site are sufficient to meet completion requirements.

Specific objectives vary with the type of removal. If cleanup levels are necessary as part of a specific objective, OSCs/RPMs employ several methods to determine these levels. Examples of current practice include applying an appropriate Federal or State ARAR, consulting a Regional risk assessor, or requesting support from ATSDR or ERT.

Specific objectives that clearly define the scope of the removal action are particularly important when the site poses multiple hazards and the response actions will be conducted in phases. OSCs/RPMs should always consider how the removal action would best contribute to the efficient performance of any remedial action to be taken, as required under CERCLA section 104(a)(2). OSWER Publication 9360.0-13, "Guidance on Implementation of the 'Contribute to Remedial Performance' Provision" (April 6, 1987), provides additional guidance on implementing CERCLA section 104(a)(2). For example, if EPA or the State plans to begin a long-term remedial action at the site in 2 years, the removal action should be designed to ensure that the site is stabilized until remedial action begins. The threats that meet the NCP removal criteria should be fully addressed, if possible, given the statutory limits on removal actions.

Determination of Removal Schedule

The general schedule for removal activities, including both the start and completion time for the non-time-critical removal action, should be part of the EE/CA. (A time-critical or emergency removal action may occur at any point from the planning phase to the completion of a non-time-critical removal action.) Although EE/CAs are only required when a planning period of at least 6 months is available, the nature of the threat may still dictate that action be initiated within 12 months or some other specific time period. The start date may also be influenced by weather, PRP negotiations, or Regional resources. For example, Regions should consult with Headquarters prior to taking any early action requiring funding beyond the Region's allowance. Also, weather can affect the schedule if the removal is to be implemented before winter. The time available before the removal action can be a significant factor in evaluating alternative technologies, since implementing technologies can necessitate considerable lead time.

The completion time should also be estimated for the removal action, considering the nature of the threat. It may be necessary to achieve beneficial results within a certain time frame to ensure adequate protection of public health and the environment. The time needed to sample treated wastes or other media prior to disposal should be factored into the schedule. Another important factor influencing the removal schedule is the statutory limit on Fund-financed removal actions. For Fund-lead sites not expected to qualify for either the emergency or consistency exemptions, the OSC/RPM should select a removal action alternative that can be implemented within the statutory limits. For Fund-lead sites expected to qualify for an exemption, the objective should be to select a

2.5 IDENTIFICATION OF REMOVAL ACTION SCOPE, GOALS, AND OBJECTIVES (CONTINUED)

removal action alternative that can be implemented within a reasonable time limit. Factors such as weather and the availability of Regional resources may also affect the completion time.

The flexibility in the removal schedule can vary greatly from site to site. Some sites may require a strict schedule, while others allow wider latitude in start and completion times. For a PRP-lead site the 1-year statutory restriction on removal actions is not applicable. In such cases, it may be advisable to establish a removal schedule in an administrative order. The schedule established for a site can be an important decision criterion to evaluate removal action alternatives based on their implementation times.

For More Information:

1. CERCLA:
   §104(a)(2), Removal Action
   §104(c)(1), Statutory Limits
2. NCP §300.415(b)(2)(i)-(viii), Appropriateness Factors
3. OSWER Publication 9360.0-13, "Guidance on Implementation of the 'Contribute to Remedial Performance' Provision" (April 6, 1987).

2.6 IDENTIFICATION AND ANALYSIS OF REMOVAL ACTION ALTERNATIVES

Based on the analysis of the nature and extent of contamination and on the cleanup objectives developed in the previous section, the OSC/RPM should identify and assess a limited number of alternatives appropriate for addressing the removal action objectives. If the information a Region typically uses to evaluate action alternatives is not sufficient, or if data quality is suspect, OSCs/RPMs should collect any additional technical information needed. If EPA is conducting oversight activities at the site, PRPs or State agencies may provide the information.

Treatment Technologies

Whenever practicable, the alternatives selection process should consider the CERCLA preference for treatment over conventional containment or land disposal approaches to address the principal threat at a site. Although CERCLA section 121(b) appears to apply only to remedial actions, the overall strategy scheme leads to the conclusion that this preference is also an appropriate goal for removal actions. Removal actions, however, cannot conform entirely to requirements for remedial actions because of site related time constraints and statutory limits on remedial actions. To identify alternatives, the OSC/RPM can draw from EPA experience with the particular technologies and contaminants involved, as well as technical advice from ERT, Office of Research and Development's (ORD)-START, the Technology Innovation Office (TIO), the Superfund Innovative Technology Evaluation program, EPA laboratories and task forces, technology vendors, and other sources.

2.6 IDENTIFICATION AND ANALYSIS OF REMOVAL ACTION ALTERNATIVES (CONTINUED)

While treatability studies often need not be performed for proven technologies, in many cases a study is necessary to assure the attainment of treatment objectives. An EE/CA often allows time to plan and conduct a treatability study.

OSCs/RPMs should refer to OSWER Publication 9380.0-17, "Furthering the Use of Innovative Treatment Technologies in OSWER Programs" (August 1991), EPA/540/2-90/004, PB91-921366, for further guidance on assessing treatment options.

Based on the available information, only the most qualified technologies that apply to the media or source of contamination should be discussed in the EE/CA. The use of presumptive remedy guidance can in many cases provide an immediate focus to the discussion and selection of alternatives, speeding the process by limiting the universe of effective alternatives for the non-time-critical removal action. Presumptive remedies involve the use of remedial technologies that have been selected in the past at similar sites or for similar contaminants. By evaluating technologies that have been consistently selected at similar sites, a presumption can be developed that a particular remedy or set of remedies is appropriate for a specific site type. EPA is developing several presumptive remedies for a variety of response situations. Currently, information is available for wood treater sites in OSWER Publications 9355.0-46FS and 9355.0-46, "Technology Selection Guide for Wood Treater Sites" (May 1993), PB93-963505. This information was previously cited as OSWER Publications 9360.0-46FS and 9360.0-46. OSWER guidance is under development for solvent and municipal landfill sites.

A limited number of alternatives, including any identified presumptive remedies, should be selected for detailed analysis. Each of the alternatives should be described with enough detail so that the entire treatment process can be understood. For example, if one of the alternatives is incineration, information on whether the incineration will occur on-site or off-site should be provided, as well as the volume of waste to be treated, the disposition of the treatment residuals, and any ARARs that would affect significantly the action, such as the land disposal restrictions. The technical implementability of this set of potentially applicable alternatives can then be evaluated based on readily available information from the site characterization phase. Specific technologies may not be applicable to the treatment of wastes in the concentration and form found at the site, and so may be disregarded. The OSC/RPM, however, must avoid even the appearance that a technology has been pre-selected. All selected technologies should be fully considered.

Treatment Technology Information Sources

Appendix D from OSWER Publication 9355.3-01, "Guidance for Conducting Remedial Investigations and Feasibility Studies (RI/FS) Under CERCLA" (October 1988), EPA/540/G-89/004, PB89-184626, provides a bibliography on various treatment technologies. In addition, EPA's Risk Reduction Engineering Laboratory is responsible for planning, implementing, and managing technology research, development, and demonstration programs. OSWER Publication 9380.3-03, "Inventory of Treatability Study Vendors" (March 1990), EPA/540/2-90/003a, PB91-228395, helps link the researcher and the user community.

Three additional databases can assist OSCs/RPMs in evaluating the effectiveness and availability of various treatment technologies. The Alternative Treatment Technology Information Center (ATTIC) is an on-line computer database that may be accessed with a personal computer and modem by calling 301-670-3808. ATTIC is a comprehensive, automated system that

integrates hazardous waste data into a centralized, searchable resource. Data about hazardous waste treatment technologies are found in many forms in this system, including:

- Literature search databases
- Expert lists
- Treatability databases
- Fate and transport databases
- Cost models
- Case histories
- Expert systems.

The central ATTIC database contains more than 1,400 technical documents collected in a key-word-searchable format. ORD Publication EPA/600/M-91/049, "Alternative Treatment Technology Information Center–ATTIC Brochure" (August 1991) provides additional information.

Another database operated by TIO is the Technology Vendor Information System for Innovative Treatment Technologies (VISITT). This database facilitates communication between technology vendors and government and private cleanup personnel and describes the capabilities and experience vendors have with innovative technologies. The database is useful in developing engineering studies and designs. The VISITT Hotline at 1-800-245-4505 can provide OSCs/RPMs with additional user information.

The Cleanup Information Bulletin Board (CLU-IN) provides electronic message capabilities, directories, on-line bulletins, and other cross-database files on innovative technologies. Special interest groups exist within the system specifically for OSCs/RPMs. CLU-IN can be accessed with a computer, modem line, and telecommunications software by calling 301-589-8366.

Defined alternatives are evaluated against the short- and long-term aspects of three broad criteria: effectiveness, implementability, and cost. Subcriteria to be evaluated under each of the criteria are identified in Exhibit 7 on the following page.

Effectiveness

The effectiveness of an alternative refers to its ability to meet the objective within the scope of the removal action. This section of the EE/CA should evaluate each alternative against the scope of the removal action and against each specific objective for final disposition of the wastes and the level of cleanup desired. These objectives should be discussed in terms of protectiveness of public health and the environment.

Overall Protection of Public Health and the Environment

How well each alternative protects public health and the environment should be discussed in a consistent manner. This discussion draws on assessments conducted under other evaluation criteria, including long-term effectiveness and permanence, short-term effectiveness, and compliance with ARARs.

EXHIBIT 7
Objectives/Criteria To Be Used In Comparative Analysis of Alternatives

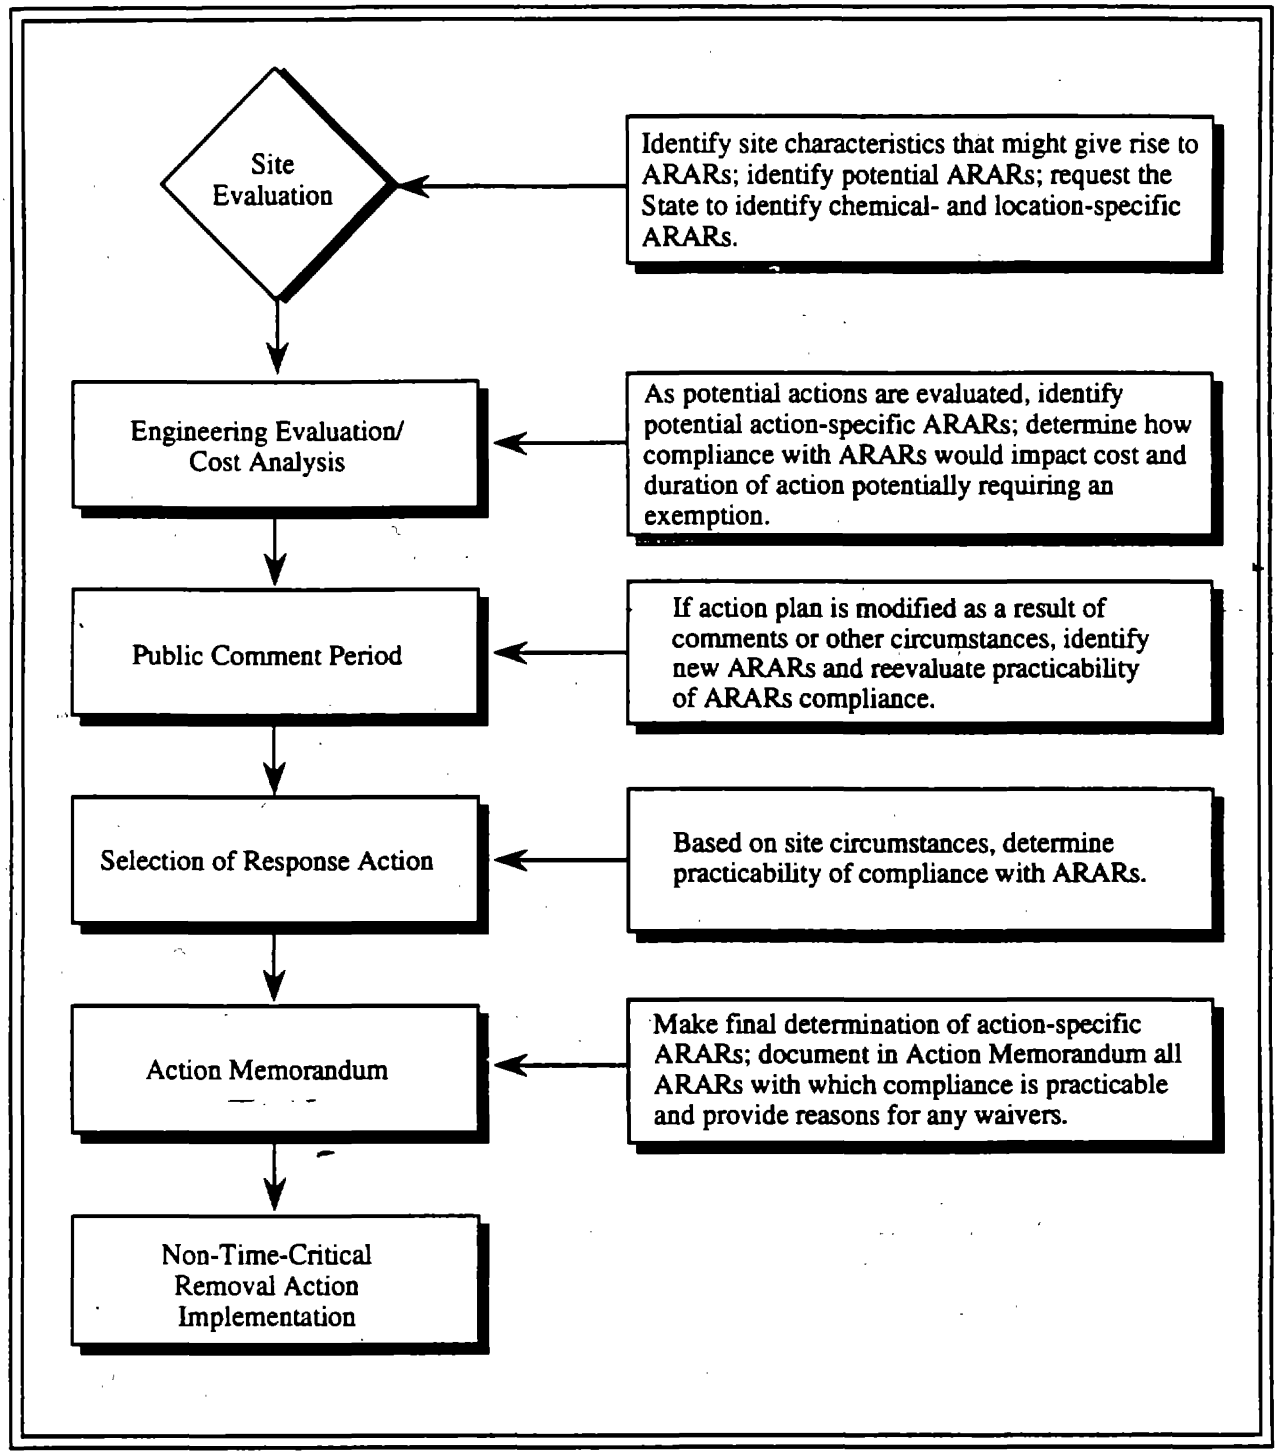
- ❑ Effectiveness
  - ❑ Protectiveness
    - ❑ Protective of public health and community
    - ❑ Protective of workers during implementation
    - ❑ Protective of the environment
    - ❑ Complies with ARARs
  - ❑ Ability to Achieve Removal Objectives
    - ❑ Level of treatment/containment expected
    - ❑ No residual effect concerns
    - ❑ Will maintain control until long-term solution implemented
- ❑ Implementability
  - ❑ Technical Feasibility
    - ❑ Construction and operational considerations
    - ❑ Demonstrated performance/useful life
    - ❑ Adaptable to environmental conditions
    - ❑ Contributes to remedial performance
    - ❑ Can be implemented in 1 year
  - ❑ Availability
    - ❑ Equipment
    - ❑ Personnel and services
    - ❑ Outside laboratory testing capacity
    - ❑ Off-site treatment and disposal capacity
    - ❑ PRSC
  - ❑ Administrative Feasibility
    - ❑ Permits required
    - ❑ Easements or right-of-ways required
    - ❑ Impact on adjoining property
    - ❑ Ability to impose institutional controls
    - ❑ Likelihood of obtaining an exemption from statutory limits (if needed)
- ❑ Cost
  - ❑ Capital cost
  - ❑ PRSC cost
  - ❑ Present worth cost

2.6 IDENTIFICATION AND ANALYSIS OF REMOVAL ACTION ALTERNATIVES (CONTINUED)

The discussion should focus on how each alternative achieves adequate protection and describe how the alternative will reduce, control, or eliminate risks at the site through the use of treatment, engineering, or institutional controls. This evaluation should identify any unacceptable short-term impacts.

Compliance with ARARs and Other Criteria, Advisories, and Guidance

Section 300.415(i) of the NCP requires that Fund-financed removal actions under CERCLA section 104 and removal actions pursuant to CERCLA section 106 attain ARARs under Federal or State environmental laws or facility siting laws, to the extent practicable considering the urgency of the situation and the scope of the removal. At certain sites, ARARs may form the basis of the removal action objectives.



The detailed analysis should summarize which requirements are applicable or relevant and appropriate to an alternative and describe how the alternative meets those requirements. To ensure a full consideration of potential ARARs, OSCs/RPMs may choose to employ a summary table to list potential ARARs. OSCs/RPMs will then be able to quickly identify particular requirements in order to plan for compliance or eliminate requirements not of concern for a given site or alternative.

Since the evaluation of a site will produce data relatively quickly on the location of a release and on the chemical constituents of concern, chemical-specific ARARs and location-specific ARARs should be identified as promptly as possible upon request by the OSC/RPM. Therefore, only State standards that are promulgated, identified by the State in a timely manner, and more stringent than Federal requirements may be applicable or relevant and appropriate. Action-specific ARARs should be identified later in the process after qualified cleanup technologies are chosen for analysis in the EE/CA. The process for identifying and evaluating ARARs during non-time-critical removal actions is shown in Exhibit 8 on the following page.

In addition to ARARs, EPA may, as appropriate, identify other Federal or State advisories, criteria, or guidance to be considered (TBC) for a particular release. TBCs are not required by the NCP; rather, TBCs are meant to complement the use of ARARs. Because ARARs do not exist for every chemical or circumstance, TBCs may be very useful in determining what is protective of a site or how to carry out certain actions or requirements. A list of TBCs, such as the EPA Spill Cleanup Policy, Health Effects Assessments, EPA's Ground Water Protection Strategy, and advisories issued by the Fish and Wildlife Service and the National Marine Fisheries Service under the Fish and Wildlife Coordination Act, can be found in the NCP Proposed Rule Preamble, 53 FR 51449-51450 (December 21, 1988).

The EnviroText Retrieval System, a joint project of EPA, DOE, DOD, the Department of Justice, and the U.S. Army, will be a user-friendly, full-text library search system of multimedia environmental laws. On-line service as a pilot program is expected to start in Fall 1993, and should assist greatly in considering potential ARARs at any given site.

EXHIBIT 8
Identification and Evaluation of ARARs During Non-Time-Critical Removal Actions

2.6 IDENTIFICATION AND ANALYSIS OF REMOVAL ACTION ALTERNATIVES (CONTINUED)

Long-Term Effectiveness and Permanence

This evaluation assesses the extent and effectiveness of the controls that may be required to manage the risk posed by treatment residuals and/or untreated wastes at the site. The following components should be considered for each alternative:

- Magnitude of Risk. This criterion looks at the effectiveness of the alternative and assesses the risk from waste and residuals remaining at the conclusion of site activities. This component also evaluates whether the alternative contributes to future remedial objectives. If the non-time-critical removal action is an interim step and is expected to be followed by remedial action, this factor could be reduced in scope or deleted, if appropriate. If the non-time-critical action is the last action anticipated for a site or release, then the magnitude of risk should be fully evaluated for the action.

- Adequacy and Reliability of Controls. A completed removal action may require PRSC, those response activities necessary to sustain the integrity of a Fund-financed removal action following its conclusion (see Chapter 1). After the removal is completed, PRSC costs may be paid by the PRP, State or local government, or the remedial program.

Reduction of Toxicity, Mobility, or Volume Through Treatment

EPA's policy of preference for treatment (i.e., for technologies that will permanently and significantly reduce toxicity, mobility, or volume of the hazardous substances as their principal element) requires evaluation based upon the following subfactors for a particular alternative:

- The treatment process(es) employed and the material(s) it will treat
- The amount of the hazardous materials to be destroyed or treated
- The degree of reduction expected in toxicity, mobility, or volume
- The degree to which the treatment will be irreversible
- The type and quantity of residuals that will remain after treatment
- Whether the alternative will satisfy the preference for treatment.

The ability of the treatment technology to reduce the principal threats posed by the release, including the extent to which the toxicity, mobility, or volume of the contaminants are reduced (either alone or in combination) may be subject to time and applicability restraints, and may be beyond the scope of an interim removal action when remedial action is indicated.

Short-Term Effectiveness

The short-term effectiveness criterion addresses the effects of the alternative during implementation before the removal objectives have been met. Alternatives should also be evaluated with respect to their effects on human health and the environment following implementation. The following factors should be addressed as appropriate for each alternative:

- Protection of the Community. This factor addresses any risk to the affected community that results from implementation of the proposed action, whether from

air quality impacts, fugitive dusts, transportation of hazardous materials, or other sources.

- Protection of the Workers. This factor assesses any threats to site workers and the effectiveness and reliability of protective measures that would be taken.
- Environmental Impacts. This factor evaluates the potential adverse environmental impacts from the implementation of each alternative. The factor also assesses the reliability of mitigation measures in preventing or reducing the potential impacts.
- Time Until Response Objectives Are Achieved. This factor estimates the time needed to achieve protection for the site itself or for individual elements or threats associated with the site.

Implementability

The implementability criterion addresses the technical and administrative feasibility of implementing an alternative and the availability of various services and materials required during its implementation. The following factors should be considered under this criterion.

Technical Feasibility

The EE/CA must assess the ability of the technology to implement the remedy. Technical difficulties were initially identified during development of alternatives and should be addressed again in detail for the alternative as a whole. Each alternative should be evaluated for implementation factors such as assembling, staffing, and operating the alternative within the time frames in the removal schedule.

The reliability of the technology is also of concern, as technical problems associated with implementation may delay the schedule. Each alternative should be evaluated for technology maturity, prior use under similar conditions for similar wastes, and possible difficulty in operation once it is constructed. Operational difficulties could include the frequency or complexity of equipment maintenance or controls, the need for raw materials, or the need for a large technical staff. Potential impacts on the local community during construction operations should also be evaluated.

The EE/CA should consider environmental conditions not only with respect to the operation phase of the alternative, but also to the set-up and construction phase. Certain technologies may be difficult to construct or operate in remote locations. Climate or terrain may severely impact or eliminate specific alternatives from consideration. For example, an alternative that uses an oil/water separator or sedimentation tank may be unusable at freezing temperatures. Temperature and time of year may directly impact a technology's ability to reach a specific site. For example, a rainy season may make roads to the site inaccessible. Not only will local terrain affect the ability to locate an alternative, but it may also affect performance. For example, a site located in a valley may be susceptible to inversions or limited air currents, therefore making incineration unacceptable.

Potential future remedial actions should also be discussed. Remedial action or a non-time-critical removal action that completely cleans up an NPL site may trigger the five-year review

requirements of CERCLA section 121(c). This evaluation should also consider the operation of PRSC measures or operation and maintenance (O & M). This discussion should depict how difficult it would be for EPA to implement these future remedial actions. This is particularly applicable to an interim action where additional action is expected.

If the site will be receiving long-term remedial treatment, the EE/CA must determine if each alternative contributes to the efficient performance of any anticipated remedial activities. CERCLA section 104(a)(2) states that a removal action should, to the extent practicable, contribute to the efficient performance of any long-term remedial action with respect to the release or threatened release concerned. Removal actions that do contribute may be eligible for an exemption from the $2 million/12-month statutory limit on removal actions. OSWER Publication 9360.0-12A, "Final Guidance on Implementation of the 'Consistency' Exemption to the Statutory Limits on Removal Actions" (June 12, 1989), PB90-274465/CCE, states that removal actions should be designed to avoid wasteful, repetitive, short-term actions that do not contribute to the efficient, cost-effective performance of a long-term remedial action.

In some cases, it may not be easy to demonstrate removal action consistency with future remedial action. Remedial actions often cannot be anticipated when an EE/CA is being developed for a non-time-critical removal action. It may be difficult to show with reasonable certainty that a removal option would be consistent with a future remedial action. Section 104(a)(2) of CERCLA provides for discretion in using the practicability standard. Accordingly, OSCs/RPMs should avail themselves of this discretion when developing and evaluating removal action alternatives that would provide for partial cleanups of sites.

The ability to monitor the effectiveness of the alternative may also be considered in the EE/CA. These monitoring considerations would generally not be evaluated for Fund-lead non-time-critical removal actions where remedial work was planned.

Administrative Feasibility

The administrative feasibility factor evaluates those activities needed to coordinate with other offices and agencies. The administrative feasibility of each alternative should be evaluated, including the need for off-site permits, adherence to applicable nonenvironmental laws, and concerns of other regulatory agencies. Factors that should be considered include, but are not limited to, the following:

- Statutory Limits. Each alternative should be evaluated for its compliance with the statutory limits on removal actions. If an alternative requires a statutory exemption from the $2 million or 12-month limit, the EE/CA should evaluate whether the site qualifies. If the time or money needed to implement the alternative will exceed the statutory limit for removal actions, an exemption request, which is part of the Action Memorandum, should be submitted to Headquarters for review as soon as possible. Headquarters approval is only required for non-NPL consistency waivers and for emergency waivers (money, not time).

- Permits and Waivers. The EE/CA should evaluate whether each alternative will require off-site permits (e.g., building permits). Other factors that may affect the administrative feasibility include the need for easements, right-of-way agreements, or zoning variances.

2.6 IDENTIFICATION AND ANALYSIS OF REMOVAL ACTION ALTERNATIVES (CONTINUED)

Availability of Services and Materials

The EE/CA must determine if off-site treatment, storage, and disposal capacity, equipment, personnel, services and materials, and other resources necessary to implement an alternative will be available in time to maintain the removal schedule. Availability of funds to meet PRSC requirements is also a factor. Several important availability factors are:

- Personnel and Technology. Using the removal action schedule as a guide, the EE/CA should determine whether a specific alternative will be available from the manufacturer. Other technologies may require a large number of skilled laborers or specialists (e.g., welders, pipe fitters, chemical engineers) that may not be readily available if the site is remote, thus impacting the ability to assemble the removal action alternative.

- Off-Site Treatment, Storage, and Disposal. If off-site removal and treatment of the waste is being considered, the EE/CA should address the adequacy of off-site capacity. If the site is in a remote location, this type of service may not be available or may be extremely costly because of transportation expenses. OSCs/RPMs should review OSWER Publication 9834.11, "Revised Procedures for Implementing Off-Site Response Actions" (November 13, 1987), PB91-139282/CCE, before evaluating this option. The OSC/RPM and Regional off-site contact should discuss whether there are treatment facilities in compliance with the off-site policy that can accept the type of CERCLA waste at the site. [A final rule addressing this issue is expected in 1993.]

- Services and Materials. This factor involves considering such services as laboratory testing capacity and turnaround for chemical analyses, adequate supplies and equipment for on-site activities, or installation of extra utilities (e.g., power lines, sewer connections).

- Prospective Technologies. This factor assesses whether specific technologies are generally available for the site. Promising technologies sometimes require further development before they can be applied at full-scale. The EE/CA should indicate when a technology would be available for full-scale use. Also, if time allows, the OSC/RPM may be able to develop specifications to allow competitive bidding for a treatment contract. This would be of particular use in developing innovative technologies.

State (Support Agency) Acceptance

The State (or support agency in the case of State-lead sites) may have technical and administrative concerns. Since States may review the alternatives, their concerns should be considered in determining the recommended alternative in the EE/CA and in the final selection of the alternative in the Action Memorandum.

2.6 IDENTIFICATION AND ANALYSIS OF REMOVAL ACTION ALTERNATIVES (CONTINUED)

Community Acceptance

As with State acceptance, community acceptance of an alternative will be considered when making a recommendation in the EE/CA and in the final selection of the alternative in the Action Memorandum.

Cost

Each removal action alternative should be evaluated to determine its projected costs. The evaluation should compare each alternative's capital and PRSC costs. The present worth of alternatives that will last longer than 12 months should be calculated. In certain cases, OSCs/RPMs may conduct a sensitivity analysis of the present worth calculations.

To compare the cost of each alternative, the direct and indirect capital costs and the PRSC costs of each alternative should be projected. OSWER Publication 9360.0-02C, "Removal Cost Management System: Version 3.2" (May 1990), EPA/540/P-90/003, PB90-272691, provides guidance on performing cost projections and daily cost tracking. The following items are considered capital costs and PRSC costs:

- Direct capital costs
  - Construction costs
  - Equipment and material costs
  - Land and site acquisition costs
  - Buildings and services costs
  - Relocation expenses
  - Transport and disposal costs
  - Analytical costs
  - Contingency allowances
  - Treatment and operating costs
- Indirect capital costs
  - Engineering and design expenses
  - Legal fees and license or permit costs
  - Start-up and shakedown costs
- Annual PRSC costs
  - Operational costs
  - Maintenance costs
  - Auxiliary materials and energy
  - Disposal of residuals
  - Monitoring costs
  - Support costs.

Many sources of cost information exist, including the ERCS contract price list, vendor estimates, and estimates for similar projects. For items not currently on the ERCS list and for projects where outside bids are being considered, cost estimates more than 12 months old should be updated using an appropriate economic index, such as the Engineering News Record Construction Cost Index for construction costs, the Marshall and Stevens Index for treatment facility costs, the American City and County Municipal Cost Index for manpower costs, and the

2.6 IDENTIFICATION AND ANALYSIS OF REMOVAL ACTION ALTERNATIVES (CONTINUED)

Producer Price Index for Finished Goods, published by the U.S. Department of Labor in the Monthly Labor Review. All these information sources can be found in Regional and/or public libraries.

After identifying and estimating the costs, OSCs/RPMs should calculate the present worth for removal action alternatives that will last longer than 12 months. Present worth analysis evaluates expenditures that occur over different time periods by discounting all future costs, usually PRSC costs, to a common base year, usually the present year. Present worth analysis produces a single figure representing the amount of money that, if invested in the base year and dispersed as needed, would cover all costs associated with the alternative. This analysis is particularly important when comparing technologies with different operating lifetimes. The final present worth figure and the assumptions used in calculating that figure should be included in the EE/CA. The detailed computations should be attached as an appendix to the EE/CA.

For alternatives that include only PRSC after 1 year from the start of the removal action, the total cost of the option over the full life of the project should be calculated. In comparing alternatives, however, OSCs/RPMs should use the cost of the option to EPA for 1 year, provided that all PRSC costs will be assumed by another party after 1 year. OSWER Publication 9355.3-20 "Revisions to OMB Circular A-94 on Guidelines and Discount Rates for Benefit Cost Analysis" (June 25, 1993) provides information on discount rates for present worth calculations.

In addition, OSCs/RPMs should determine whether a sensitivity analysis is warranted. A sensitivity analysis assesses the effect that variations in specific assumptions associated with design, implementation, operation, discount rate, and effective life of an alternative can have on the present worth. The sensitivity of such costs to uncertainties can be observed by varying the cost assumptions and noting their effect on the present worth. A sensitivity analysis might be appropriate when uncertainties exist about the amount of waste present, how quickly a technology can perform, or the future price of cleanup services.

2.7 COMPARATIVE ANALYSIS OF REMOVAL ACTION ALTERNATIVES

Once the alternatives have been described and individually assessed against the criteria, a comparative analysis should be conducted to evaluate the relative performance of each alternative in relation to each of the criteria. This is in contrast to the preceding analysis in which each alternative was analyzed independently without consideration of other alternatives. The purpose of the comparative analysis is to identify the advantages and disadvantages of each alternative relative to one another so that key tradeoffs that would affect the remedy selection can be identified.

2.8 RECOMMENDED REMOVAL ACTION ALTERNATIVE

The EE/CA should identify the action that best satisfies the evaluation criteria based on the comparative analysis in the previous section. This description should briefly describe the evaluation process used to develop the recommended action. For both Fund-lead and PRP-lead EE/CAs, EPA should determine the recommended action. This determination may be placed in the administrative record file concurrently with the EE/CA. This section of the EE/CA may enhance public involvement efforts by describing clearly why the alternative was recommended. Because the EE/CA is open to public comment and evaluation and because EPA is required to prepare

2.8 RECOMMENDED REMOVAL ACTION ALTERNATIVE (CONTINUED)

a written response to significant comments, the recommended alternative may not always be the final alternative selected in the Action Memorandum. The Action Memorandum and the administrative record should provide enough detail to justify the final alternative selected.

Comparison of EE/CA to RI/FS

EE/CA Process

1. **EE/CA Approval Memorandum**
   - Secure management approval and funding for EE/CA
   - Include finding of actual or threatened release and, if present, an imminent and substantial endangerment and general site information and costs
   - Document that situation meets NCP criteria and action is non-time-critical

EE/CA

2. **EE/CA Executive Summary**
   - Identifies threat
   - Describes removal action objectives
   - Summarizes recommended action

3. **Site Characterization**
   - Collect site description and background
   - Identify previous removal actions
   - Determine source, nature, and extent of contamination
   - Collect analytical data
   - Perform streamlined risk evaluation
   - Identify contaminant- and location-specific ARARs

4. **Identification of Removal Action Objectives**
   - Evaluate statutory limits
   - Determine scope of removal action
   - Determine schedule of removal action

RI/FS Process*

1a. **Pre-RI/FS Scoping**
   - Collect existing data
   - Visit site/identify areas of concern
   - Generate statement of work

1b. **RI/FS Scoping**
   - Collect/analyze existing data
   - Determine need for/implement additional studies
   - Develop preliminary remedial action alternatives/objectives
   - Evaluate need for treatability studies
   - Begin preliminary identification of ARARs
   - Identify data needs/data quality objectives
   - Design data collection program
   - Develop work plan
   - Identify health and safety protocols

REMEDIAL INVESTIGATION

2. **Site Characterization**
   - Investigate site physical characteristics
   - Define sources of contamination
   - Determine nature and extent of contamination
   - Conduct laboratory analyses
   - Conduct data analyses
   - Conduct baseline risk assessment
   - Identify contaminant- and location-specific ARARs
   - Define remedial action goals
   - Draft RI Report

Model Notice of Decision Not To Use Special Notice Procedures*

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
Region []

[ADDRESS]

NOTICE OF DECISION NOT TO USE SPECIAL NOTICE PROCEDURES
URGENT LEGAL MATTER**
CERTIFIED MAIL: RETURN RECEIPT REQUESTED

[Date]

[Name and Address of Potentially Responsible Party]
[c/o Registered Agent or Contact Person]

Re: [Name of Site]
[Address or location of Site] (the "Site")

Dear [Name of PRP if an individual; "sir or madam" otherwise]:

This letter notifies you that the United States Environmental Protection Agency (EPA) has determined not to use special notice procedures pursuant to Section 122(e) of the Comprehensive Environmental Response, Compensation, and Liability Act, as amended (CERCLA), at the above-referenced site regarding the [RI/FS] [RI/FS for operable unit] [RD/RA] [RD/RA for operable unit].

NOTICE OF POTENTIAL LIABILITY

As indicated in the general notice letter previously sent to you, EPA has evaluated information in connection with the investigation of the site. EPA has information indicating that you may be a potentially responsible party (PRP) as defined at Section 107(a) of the CERCLA, 42 U.S.C. 9607(a), with respect to hazardous substances at this site. Potentially responsible parties under CERCLA include current and former owners and operators of the site as well as persons who arranged for disposal or treatment of hazardous substances sent to the site, or persons who accepted hazardous substances for transport to the site.

DECISION NOT TO USE SPECIAL NOTICE

In this instance EPA has decided that it is inappropriate to invoke the Section 122(e) special notice procedures. EPA believes that using such special notice procedures would not facilitate an agreement between EPA and the PRPs and would not expedite the response action at the site. (Provide specific reasons why the special notice procedures would not facilitate an agreement and

---

* Model letter from OSWER Publication 9834.10-1b, "Model Notice Letters" (Feb. 7, 1989), PB91-139279/CCE.

** This letter may need to be modified if a general notice letter has not been sent to include some of the information typically conveyed in that letter.

would not expedite a response. Examples may include where past dealings with the PRPs strongly indicate they are unlikely to negotiate a settlement, where EPA believes the PRPs have not been negotiating informally to this point in good faith, or where PRPs lack the resources to conduct response activities.)

The decision not to use the special notice procedure does not preclude you from entering into discussions with EPA regarding your participation in response activities at the site. The decision simply means that EPA will not use the special notice procedures to govern any future discussions. EPA encourages all PRP offers regarding settlement of this matter and cleanup of this site.

ADMINISTRATIVE RECORD

Pursuant to CERCLA Section 113(k), EPA must establish an administrative record that contains documents that form the basis of EPA's decision on the selection of a response action for a site. The administrative record files, which contain the documents related to the response action selected for this site, [will be] [are] available to the public for inspection and comment. The primary location is generally the EPA Regional office. [Include specific information regarding the location and availability of the record file.]

EPA CONTACT

If you or your attorney have any questions pertaining to this matter, please direct them to _____.

Sincerely,

OFFICE OF LAND AND EMERGENCY MANAGEMENT
WASHINGTON, D.C. 20460

January 17, 2024

MEMORANDUM

SUBJECT: Updated Residential Soil Lead Guidance for CERCLA Sites and RCRA Corrective Action Facilities

FROM: Barry N. Breen
Principal Deputy Assistant Administrator

TO: Regional Administrators, Regions 1 - 10

PURPOSE

Reducing childhood lead exposure is an Environmental Protection Agency (EPA) priority. Consistent with the best available science, the Agency's Strategy to Reduce Lead Exposures and Disparities in U.S. Communities, and the Federal Action Plan to Reduce Childhood Lead Exposures and Associated Health Impacts, the Office of Land and Emergency Management (OLEM) is updating its residential soil lead regional screening level (RSL) and regional removal management level (RML) for the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), commonly known as "Superfund" remedial and removal programs, respectively, and Resource Conservation and Recovery Act (RCRA) Corrective Action program. The information and recommendations in this guidance also apply to federal facility cleanup programs subject to CERCLA section 120, and potentially to federal agencies using response action authorities delegated to them under Executive Order 12580 (OFR, 1987).

Screening Residential Soil Lead Sites

What is a regional screening level (RSL)? RSLs are screening tools used to help identify and define areas that may need further evaluation.

What is a removal management level (RML)? RMLs are screening tools used to help prioritize and define areas that may pose the greatest threat to human health.

The RSLs and RMLs are generally not default preliminary remediation goals (See Footnote 11) and cleanup levels.

When evaluating residential sites with soil lead contamination,[1] OLEM recommends:

[1]For the purpose of this guidance, a residential site with soil lead contamination (residential lead site) is defined as any areas where children have unrestricted access to lead contaminated soil which include, but are not limited to, properties containing single- and multi-family dwellings, apartment complexes, vacant lots in residential areas, schools, day-care

Regional Screening Level

- EPA regions should use a residential soil lead RSL of 200 parts per million (ppm).[2]
- However, EPA regions should use a RSL of 100 ppm[3] if an additional source of lead is identified (e.g., lead water service lines, lead-based paint, non-attainment areas where the air lead concentrations exceed National Ambient Air Quality Standards [NAAQS]). The recommended RSL of 100 ppm considers aggregate lead exposure and increased risk to children living in communities with multiple sources of lead contamination. In making site-specific decisions on when to use an RSL of 100 ppm, EPA regions may use national data sets identified by OLEM for this purpose. EPA regions may also use site-specific sources of information (e.g., data from the local health department or local public water system), alone or in combination with national data sets, to select an appropriate RSL of either 100 ppm or 200 ppm. EPA regions should document the site-specific rationale for the selected RSL.
- Federal-led RCRA corrective action residential soil lead cleanups should use an RSL of 200 ppm or 100 ppm based on the factors discussed above. EPA strongly encourages states that are authorized for RCRA Corrective Action to use these RSLs in their state-led residential soil lead cleanups.

Removal Management Level

- EPA regions should use a residential soil lead RML of 200 ppm.

NOTICE

Please note, the statements in this document are intended solely as guidance. This document is not intended, nor can it be relied upon, to create any rights enforceable by any party in litigation with the United States. EPA will accept public input and evaluate new scientific evidence, as appropriate.

BACKGROUND

Two guidance documents, (1) Revised Interim Soil Lead Guidance for CERCLA Sites and RCRA Corrective Action Facilities (USEPA, 1994) and (2) Clarification to the 1994 Revised Interim Soil Lead (Pb) Guidance

centers, community centers, playgrounds, parks and other recreational areas and green ways. Under CERCLA and RCRA Corrective Action, screening and cleanup decisions for residential land use are based the most sensitive receptor (young children less than 7 years old). See USEPA, 1998 and 2003.

[2] Since 1994, OLEM has recommended the Integrated Exposure Uptake Biokinetic Model for Lead in Children (IEUBK) as a risk assessment tool to support environmental cleanup decisions at current and future anticipated residential sites (USEPA, 1994). The IEUBK predicts blood lead levels in young children (birth to 7 years of age) exposed to lead from several sources of exposure and routes. The current version of the model (IEUBKv2) with 5 µg/dL as the 95th percentile target blood lead level and national default lead concentrations predicts a soil lead concentration of approximately 200 ppm. The geometric mean blood lead level is 2.3 µg/dL.

[3] The IEUBKv2 with 3.5 µg/dL as the 95th percentile target blood lead level and national default lead concentrations predicts a soil lead concentration of approximately 100 ppm. The geometric mean blood lead level is 1.7 µg/dL. EPA has not evaluated the IEUBKv2 below 5 µg/dL (upper percentile of the blood lead distribution) (Brown et al., 2022). EPA has a qualitative understanding of uncertainties that may exist in applying the model outside the evaluated range, which is consistent with EPA Guidance on the Development, Evaluation, and Application of Environmental Models (See definition of mechanistic model, page 44, USEPA, 2009). EPA has used models outside the evaluated range when deemed necessary and appropriate for human health risk assessments.

for CERCLA and RCRA Corrective Action Facilities (USEPA, 1998), established OLEM's previously recommended approach for evaluating and cleaning up Superfund and RCRA Corrective Action sites with soil lead contamination. Broadly, these directives recommended a residential soil lead RSL of 400 ppm based on 10 µg/dL as the 95th percentile target blood lead level, described how to develop preliminary remediation goals (PRGs) and cleanup levels, and described a strategy to manage multiple sources of lead exposure. At the time, a blood lead level above 10 µg/dL was recognized to be associated with adverse health outcomes in children (USEPA, 1994). The science on lead has since evolved and demonstrates additional adverse health effects of lead exposure and at lower levels than previously known.

Best Available Science and Data

In 2012, the National Toxicology Program (NTP) Monograph on Health Effects of Low-Level Lead examined the evidence for adverse health effects at blood lead levels of up to 5 µg/dL and 10 µg/dL and found sufficient evidence of many different types of health effects below both levels. The NTP concluded, "In children, there is sufficient evidence that blood [lead] Pb levels <5 µg/dL are associated with increased diagnosis of attention-related behavioral problems, greater incidence of problem behaviors, and decreased cognitive performance as indicated by (1) lower academic achievement, (2) decreased intelligence quotient (IQ), and (3) reductions in specific cognitive measures" (HHS, 2012, page xviii). Further, the NTP found "sufficient evidence that blood Pb levels <5 µg/dL are associated with antisocial behavioral problems or actual criminal behavior in children from 6 to 15 years of age." For adults, the NTP found "sufficient evidence that blood Pb levels <5 µg/dL are associated with decreased renal function" and "sufficient evidence that maternal blood Pb levels <5 µg/dL are associated with reduced fetal growth" (Ibid.). Although the evidence was less definitive, the NTP also found associations of blood Pb levels <5 µg/dL with delayed puberty and decreased kidney function in children and with essential tremor in adults. The NTP concluded "that there is sufficient evidence that blood Pb levels <10 ug/dL in adults are associated with adverse effects on cardiovascular function" (HHS, 2012, page xxii).

EPA's 2013 Integrated Science Assessment for Lead (ISA) states "It is clear that Pb [lead] exposure in childhood presents a risk; further, there is no evidence of a threshold below which there are no harmful effects on cognition from Pb [lead] exposure" (USEPA, 2013, page xxxviii). Although the ISA reports, "Clear evidence of cognitive function decrements (as measured by Full Scale IQ, academic performance, and executive function) in young children (4 to 11 years old) with mean or group blood Pb [lead] levels measured at various life stages and time periods between 2 and 8 µg/dL," (USEPA, 2013, page xxxiii) it is critical to note that there is not a threshold for toxicity somewhere between blood lead levels of 2 and 8 µg/dL. Rather, a "threshold for cognitive function decrements is not discernable from the available evidence" (USEPA, 2013, page 1-20). Although there are a greater number of studies available to support effects at 5 µg/dL, cognitive function decrements in children have been found at all levels examined, including at levels as low as 2 µg/dL as identified in the 2013 ISA. The ISA also concludes that lead exposure has a causal relationship with hypertension and coronary heart disease (USEPA, 2013, page 1-29). The recommended RSLs of 200 ppm and 100 ppm are predicted using the current version of the Integrated Exposure Uptake Biokinetic Model for Lead in

Children (IEUBK) to result in geometric mean blood lead levels (2.3 µg/dL and 1.7 µg/dL, respectively) that are 0.3 µg/dL above and below, respectively 2 µg/dL.

The Agency for Toxic Substances and Disease Registry's 2020 Toxicological Profile for Lead reviewed 694 epidemiological studies that evaluated the health effects of lead in all organ systems. This updated Toxicological Profile concluded that "[f]or the most studied endpoints (neurological, renal, cardiovascular, hematological, immunological, reproductive, and developmental), effects occur at the lowest PbBs [blood leads] studied (≤5 µg/dL)" (ATSDR, 2020, page 3). Some of the more recent studies included in the Toxicological Profile provide "supporting evidence that exposures to Pb [lead] may produce effects on cognitive function in populations whose PbBs [blood leads] are well below 5 µg/dL and may extend to levels below 1 µg/dL" (ATSDR, 2020, page 168).

RATIONALE FOR UPDATED GUIDANCE

As previously stated, evolving science on lead has demonstrated additional adverse impacts of lead exposure well below 10 µg/dL since the 1994 guidance was issued. Moreover, children could be exposed to multiple sources of lead other than contaminated soil/dust (e.g., lead water service lines, lead-based paint, or non-attainment areas where the air lead concentrations exceed NAAQS) at Superfund and RCRA Corrective Action sites. Studies[4] conducted at or near Superfund sites provide evidence that aggregate lead exposure has generally resulted in blood lead levels that are higher than those of most U.S. children as indicated by the observation of a disproportionate number of elevated blood lead levels in such communities. Further, the 2013 ISA found that childhood, race and ethnicity, proximity to lead sources, residential factors (housing age), and poor nutrition may lead to increased risk of lead related health effects (USEPA, 2013, Table 1-7, page 1-79).

While evidence shows adverse health effects at the lowest levels studied, CERCLA and the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) mandate that EPA develop protective exposure levels for our sites, establishing a risk management paradigm informed by many factors including health effects at issue and the population at risk. Based on the best available science, OLEM is recommending a lower residential soil lead RSL and RML of 200 ppm and further reducing the RSL to 100 ppm when there is aggregate lead exposure. Lowering the RSL and RML is expected to increase the number of residential properties evaluated for potential cleanup under CERCLA and RCRA Corrective Action authorities.

From a risk management perspective, effectively assessing potential impacts to children from lead exposure[5] informs further evaluation of the site. This information is integral to selecting the most appropriate combination of CERCLA or RCRA Corrective Action response actions to reduce the risk from site-specific lead contamination. Through these recommendations, EPA is helping ensure that Superfund and RCRA Corrective Action residential soil lead cleanups adequately reduce childhood exposures, which, if unaddressed, could lead to lifelong adverse health effects.

[4] Klemick et. al., 2020; Khoury and Diamond, 2003; Terragraphics, 2004; Frank, et. al., 2019; Zota, et. al., 2011; Ye, et. al., 2022; U.S. EPA, 2013.

[5] CERCLA and RCRA Corrective Action residential soil lead cleanups protect the most sensitive receptor and thereby protect all other residents in the process (including pregnant women, older children, and other adults).

IMPLEMENTATION

Managing and Prioritizing Residential Soil Lead Cleanups

This guidance should be considered for all residential lead sites subject to CERCLA response and RCRA Corrective Action authorities, including those previously addressed and/or deleted from the National Priorities List (NPL).[6] EPA expects that a significant number of residential properties could undergo evaluation and cleanup because of this guidance. The existing prioritization process, which occurs at the regional level,[7] will continue. That process entails review of existing site information and overall risk in a manner consistent with the NCP and national program guidance and policies. EPA regions should work collaboratively with state, tribal, and public health agencies to prioritize addressing sites, considering factors such as current levels of exposure and communities with increased risk. Consistent with national policy, EPA will make resource decisions for residential lead sites in a manner that balances resources across all Superfund sites.

Evaluations of previously addressed sites could be conducted in support of a CERCLA five-year review or other technical review. EPA regions should consider historical site-specific documentation to determine: the extent of previous cleanup, including cleanup levels and the remedial and/or removal action objectives; the exposure assumptions used in the risk assessment at the time of response selection, including the use of site-specific environmental data (e.g., lead concentrations in various media and bioavailability); if the current version of the IEUBK blood lead level estimates are consistent with revised target blood lead levels outlined in this guidance (5 µg/dL or 3.5 µg/dL 95th percentile target blood lead level); and other appropriate considerations. EPA regions should include an assessment of the actual exposure scenarios (e.g., gardening, excavation, age of children in contact with soil, paved and unpaved surfaces) throughout both the remediated and un-remediated areas within the site, in addition to evaluating whether potential changes in cleanup levels are necessary and appropriate.

Because EPA expects a significant number of properties to undergo evaluation, EPA regions are not expected to be able to address all properties immediately. As EPA regions are prioritizing residential lead sites for evaluation and potential cleanup, OLEM continues to recommend early risk reduction strategies, which could include a combination of engineering controls (e.g., reliable barriers to mitigate risk from lead exposure) and non-engineering response actions (e.g., education and health intervention programs in conjunction with exposure reduction actions like institutional controls).[8] EPA will continue

[6] Regarding completed residential soil lead cleanups, there are post-remedy review authorities for RCRA cleanups; one is the authority to reopen permits based on new information.

[7] EPA intends to engage with other Federal agencies conducting actions under CERCLA or RCRA Corrective Action associated with lead releases from these Federal Facilities, with input from state and tribal environmental agencies, to develop a Federal Facility-specific implementation guidance. EPA's Federal Facilities Restoration and Reuse Office (FFRRO) works with EPA regions and other federal agencies to develop creative, cost-effective solutions to environmental challenges at Federal Facility Superfund Sites. When prioritizing properties at federal facilities, other federal agencies serving as the lead for these facilities should discuss prioritizing reassessment and potential response actions with its cleanup regulators (e.g., EPA and the state at NPL Sites or Sites with Superfund Alternative Approach Agreements).

[8] See Use of Early Actions at Superfund National Priorities List Sites and Sites with Superfund Alternative Approach Agreements, August 23, 2019.

to take appropriate and timely response actions under available CERCLA or RCRA Corrective Action authorities at sites where the release of lead poses an imminent and substantial danger to public health.

Integration of Removal and Remedial Authorities at Residential Lead Sites

It is important to consider the statutory and regulatory differences between removal actions and remedial actions, as well as each authority's limitation. When CERCLA was enacted, the general intent was for the program to use emergency or time-critical removal authority to address the most immediate threats, to consider the use of non-time critical removal authority when a planning period of at least six months exists before on-site activities must be initiated, and to use remedial authority for the less immediate threats. Absent time sensitivity, remedial authority generally would be used to address complex site problems that will likely require a costly, complicated response. It is important to carefully consider the specifics of each site and to clearly document the basis for determining the appropriate authority given site circumstances. Emergency and time-critical removal authorities should continue to be used in alignment with agency statutes, regulations, policy, and guidance to address the most immediate public health and environmental threats.

Collaboration at Superfund Residential Lead Sites

Multiple sources of lead contamination could be present at Superfund sites where children are at risk. The Superfund program promotes collaboration to provide a more holistic approach to reducing lead exposures at residential lead Superfund sites. Many federal, local, state, and tribal agencies have diverse legal authorities to address sources of lead exposure in communities; therefore, EPA Regions should collaborate with these entities as part of an overall site management strategy to prevent and reduce lead exposures in communities.[9]

Developing PRGs and Cleanup Levels for Residential Lead Sites

OLEM recommends using the most current version of the IEUBK to assess risk from exposure or potential exposure to soil lead contamination.[10] In the absence of more stringent regulations and standards constituting applicable, or relevant and appropriate requirements (ARARs), OLEM recommends that regions should use the most current version of the IEUBK with 5 µg/dL as the 95th percentile target blood lead level and site-specific environmental data (e.g., lead concentrations in various media and bioavailability) to develop PRGs[11] and cleanup levels for residential land use. If an

[9] The Superfund program conducted the Superfund Lead Collaboration Pilot to gather best practices for enhancing collaboration when multiple sources of lead are identified in communities near Superfund residential lead sites. OLEM will recommend these best practices where appropriate.

[10] Risk assessment questions can be directed to the site's risk assessor or the Technical Review Workgroup for Metals and Asbestos (TRW) Lead Committee. See https://www.epa.gov/superfund/lead-superfund-sites-risk-assessment.

[11] See 40 C.F.R. § 300.430(e)(2)(i) ("Initially, preliminary remediation goals are developed based on readily available information, such as chemical-specific ARARs [applicable or relevant and appropriate requirements] or other reliable information…. Remediation goals [cleanup levels] shall establish acceptable exposure levels that are protective of human health and the environment and shall be developed by considering the following: (A) Applicable or relevant and appropriate requirements under federal environmental or state environmental or facility siting laws, if available."). See USEPA, 1997.

additional source of lead (e.g., lead water service lines, lead-based paint, non-attainment areas where the lead concentrations exceed NAAQS) is identified, OLEM recommends 3.5 µg/dL as the 95th percentile target blood lead level. This adjustment considers increased risk to children living in communities with multiple sources of lead contamination. EPA regions should adjust PRGs and cleanup levels to account for uncertainty, technical limitations (i.e., detection/quantification limits),[12] and site-specific soil lead background.

Consistent with the Role of Background in the CERCLA Cleanup Program, cleanup levels should not be set at values below natural or anthropogenic background. When the IEUBK-derived cleanup level is lower than site-specific background, the cleanup level should be set at background. EPA regions should consult the 2002 Guidance for Comparing Background and Chemical Concentrations in Soil for CERCLA Sites when establishing site-specific soil lead background. In addition to the use of statistical tests, an important component of defining background concentrations is the choice of appropriate background samples, which should include consideration of the conceptual site model, natural geological lead sources for the locality, and historical/current anthropogenic activities unrelated to site releases of lead. Careful choice of residential soil samples representing discrete exposure units is also important (e.g., segregating yard samples from the house drip zone, which often has elevated lead concentrations resulting from exterior paint debris). Additional information is contained in Frequently Asked Questions About the Development and Use of Background Concentrations at Superfund Sites: Part One, General Concepts.

Relationship to TSCA §403 Hazard Standards

Residential soil lead cleanups under the Superfund, RCRA Corrective Action and Toxic Substances Control Act (TSCA) programs seek to protect the health of the most vulnerable populations (children). The studies that take place at CERCLA or RCRA Corrective Action sites involve multiple hazardous substances with potentially numerous sources of contamination and multiple pathways of exposure that require cleanup levels be developed with site-specific information. In contrast, the TSCA §403 hazard standards for bare residential soil only apply to pre-1978 target housing and certain child-occupied facilities. These hazard standards are minimum national standards that apply to lead-based paint activities (i.e., inspections, lead-hazard screens, risk assessments and abatements) to help prioritize the cleanup of residential and child-occupied facilities affected by lead based paint.

Applicability to Superfund Site Assessment and Listing

RSLs and RMLs are not used in the Hazard Ranking System (HRS) scoring calculations.[13] Sites not eligible for the NPL are assigned a no further remedial action planned (NFRAP) decision. A change in RSLs or RMLs itself will not affect HRS scoring at sites with prior NFRAP decisions or result in additional NPL sites from the NFRAP universe. EPA can reassess a NFRAP site for potential NPL eligibility if

[12] See NCP 40 CFR 300.430(e)(2)(i).

[13] The Superfund site assessment program determines if a site is eligible for placement on the NPL primarily based on application of criteria contained in the Hazard Ranking System (HRS) (40 CFR Part 300 – Appendix A- The Hazard Ranking System). The HRS is a scoring system that uses information from initial, limited investigations to assess the relative threat posed by sites for NPL listing.

additional information arises and generally relies on states and tribes to inform EPA of the need to reassess a NFRAP site for potential response action.

The EPA site assessment program also considers whether involvement by the Superfund removal program is needed at any point during the site assessment process. EPA regions should be aware of this revised guidance on RMLs when reviewing lead sampling results associated with site assessments and should consult with the Superfund removal program as appropriate.

CONCLUSION

Reducing exposure to lead can improve communities' health and wellbeing. EPA residential soil lead cleanups —combined with the education and action of individuals and communities—have proven to be an effective part of an overall strategy for reducing blood-lead levels in children. With this guidance, EPA is updating its approach for reducing lead exposure in a manner consistent with the best available science.

NOTICE

This document provides guidance to EPA and State staff. It also provides guidance to the public and to the regulated community on how EPA intends to exercise its discretion in implementing its regulations. The guidance is designed to implement national policy on these issues. The document does not, however, substitute for statutes EPA administers or their implementing regulations, nor is it a regulation itself. Thus, it does not impose legally binding requirements on EPA, States, or the regulated community, and may not apply to a particular situation based upon the specific circumstances. EPA may change this guidance in the future, as appropriate.

ADDITIONAL COPIES

This document is available on the Internet at http://www.epa.gov/superfund/.

EPA employees can obtain copies of this guidance, or copies of documents referenced in this guidance, by calling the Superfund Docket at 703-603-9232.

Non-EPA employees or members of the public can order a limited number of paper copies of EPA documents at no fee from EPA's National Service Center for Environmental Publications (NSCEP) by calling (800) 490-9198 or by placing a request at http://www.epa.gov/ncepihom/. When free copies are not available, NSCEP will refer the requestor to the National Technical Information Service (NTIS), which offers documents for a fee. NTIS can be reached by calling 1-800-553-6847 or by placing a request at http://www.ntis.gov/. Fees for these documents are determined by NTIS.

ABSTRACT

This guidance document addresses cost estimates of remedial alternatives developed during the remedial investigation/feasibility study. The goals of this guidance are to improve the consistency, completeness, and accuracy of cost estimates developed to support the Superfund remedy selection process. To help achieve these goals, the document presents clear procedures and expectations, a checklist of cost elements, and example formats. It also identifies resources for estimating costs during the feasibility study. This guide is designed to help those with varying levels of cost estimating expertise, including cost estimators, design engineers, technical support contractors, remedial project managers, and program managers.

This document updates and clarifies previous USEPA guidance for developing and documenting remedial alternative cost estimates during the feasibility study. Previous guidance superceded by this document are Chapter 3 of *Remedial Action Costing Procedures Manual, October 1987 (EPA/600/8-87/049),* and Section 6.2.3.7 of *Guidance for Conducting Remedial Investigations and Feasibility Studies under CERCLA - Interim Final, October 1988 (EPA/540/G-89/004).*

ACKNOWLEDGEMENTS

This document was produced through a joint effort of the United States Environmental Protection Agency (USEPA) Office of Emergency and Remedial Response (OERR) and the United States Army Corps of Engineers (USACE) Hazardous, Toxic, and Radioactive Waste (HTRW) Center of Expertise (CX). Technical assistance was provided under USACE Contract No. DACA45-97-D-0019 by URS Greiner Woodward Clyde Federal Services (URS).

The project management team consisted of Mike Goldstein, USEPA OERR; Stan Hanson, USACE HTRW CX; and Jon Ritterling, URS. Active members of the project workgroup were John Abraham, USEPA Office of Research and Development, National Risk Management Research Laboratory; Keith Hemmer, Project Time & Cost, Inc.; Miguel Jumilla, USACE Headquarters Cost Engineering Branch; Leslie Voss, URS; and Sid Wolf, Environmental Management Support, Inc. In addition, numerous others provided careful review and constructive comments, contributing to the overall quality of the document.

Chapter One
Introduction

In the Superfund program,[1] the remedial investigation/feasibility study (RI/FS) process is used to characterize the nature and extent of risks posed by hazardous waste sites and to evaluate potential remedial options. During the feasibility study (FS) phase of this process, cost estimates are developed for each remedial action alternative being evaluated.

The U.S. Environmental Protection Agency (USEPA) first published guidance for developing and documenting remedial alternative cost estimates during the FS as part of the *Remedial Action Costing Procedures Manual* (USEPA 1987). That document provided the basis for the discussion of cost estimating in *Guidance for Conducting Remedial Investigations and Feasibility Studies under CERCLA* (USEPA 1988). Since these documents were published, remedial alternative cost estimates prepared during feasibility studies generally have followed this basic guidance, but have typically varied in approach and content. Additionally, the number of available cost estimating resources has increased during this time. To take advantage of lessons learned and help improve the consistency, completeness, and accuracy of remedy cost estimates during the FS, this guide was prepared to update and clarify previous USEPA guidance in this policy area. Specific guidance superceded by this guide are Chapter 3 of *Remedial Action Costing Procedures Manual* (USEPA 1987) and Section 6.2.3.7 of *Guidance for Conducting Remedial Investigations and Feasibility Studies under CERCLA* (USEPA 1988).

Key Issues for Cost Estimates in Feasibility Study Reports

Cost estimates of remedial alternatives provided in feasibility study reports should clearly present the following information:

- Expected accuracy range of the cost estimate (e.g., –30 to +50 percent for detailed analysis of alternatives)
- Source references for quantity and unit cost information
- Contingency to account for possible cost overruns
- Basis for applied contingency
- Costs for professional and technical services
- Period of present value analysis (e.g., 50 years)
- Basis for period of present value analysis (e.g., time required to achieve remedial action objectives)
- Discount rate used in present value analysis (e.g., 7 percent)
- Basis for discount rate used in present value analysis (e.g., per USEPA policy)
- Major assumptions and sources of uncertainty in the overall estimate
- Analysis of sensitivity of cost estimate to uncertain factors
- Logical and organized presentation of cost estimate summaries and detailed backup information

[1] As used by this guide, "Superfund" refers to the program operated under the authority of the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) of 1980 and the Superfund Amendments and Reauthorization Act (SARA) of 1986.

1.1 Purpose of Guide

The purpose of this guide is to provide a current reference for developing and documenting cost estimates of remedial action alternatives during the FS. The goals of this guide include improving the consistency, completeness, and accuracy of cost estimates prepared during the FS. To help achieve these goals, the guide presents clear procedures and expectations, presents a checklist of cost elements and example formats, and points out resources for cost estimating.

This guide is designed to help those with varying levels of cost estimating expertise, including cost estimators, design engineers, technical support contractors, remedial project managers, and program managers.

1.2 Scope of Guide

This guide addresses cost estimates of remedial alternatives developed during the FS in support of the Superfund remedy selection process. Therefore, Superfund terms are primarily used to describe the concepts presented. However, many of these cost engineering concepts are universal in nature and could be applied to other environmental cleanup projects or programs.[2]

While cost estimates are developed at different stages of the Superfund process (Chapter 2), this guide specifically addresses the FS phase. Cost estimates are developed during the FS primarily for the purpose of comparing remedial alternatives during the remedy selection process, not for establishing project budgets or negotiating Superfund enforcement settlements.[3] During remedy selection, the cost estimate of the preferred alternative is typically carried over from the FS to the proposed plan for public comment. The subsequent cost estimate included in the record of decision (ROD) reflects any changes to the remedial alternative that occurs during the remedy selection process as a result of new information or public comment.

Finally, this guide does not address how to use cost estimates in making a remedy selection decision or how to make a cost-effectiveness determination in the Superfund program. USEPA guidance that addresses this issue can be found in *The Role of Cost in the Superfund Remedy Selection Process* (USEPA 1996).

---

[2] Examples include Superfund removal actions, Superfund enforcement settlements, Resource Conservation and Recovery Act (RCRA) corrective actions, Federal facilities cleanups, brownfields cleanups, underground storage tank remediation, installation restoration program, base realignment and closure, formerly used defense sites, and cleanup programs under State authorities.

[3] The FS remedial alternative cost estimate can be used as starting point for budgeting purposes, but adjustments may be needed based on individual agency requirements. For example, estimates may need to be revised based on project scope requirements, escalation factors may need to be added, or discount factors may need to be removed.

1.3 How to Use the Guide

This guide is intended to provide the user with the basic information necessary to develop and document cost estimates for remedial action alternatives during the FS. This guide is not meant to contain all of the information necessary to complete the cost estimate, but to be a primary reference, pointing to other resources as necessary. The objectives of each chapter and appendix are listed below:

- Chapter 1: Introduce the guide, including its purpose, scope, and use.
- Chapter 2: Provide background information on applicable regulatory and cost engineering concepts, including the Superfund process, role of project definition in cost estimates, cost estimating within Superfund, and cost estimating during the FS.
- Chapter 3: Provide a cost element checklist to help identify capital, annual operation and maintenance (O&M), and periodic costs to include in the cost estimate for a remedial action alternative.
- Chapter 4: Provide guidelines for conducting a present value analysis, including period of analysis and discount rate.
- Chapter 5: Provide steps to develop the basic cost estimate for a remedial action alternative, including alternative description, identification of cost element structure, estimation of cost elements, application of contingency, present value analysis, sensitivity analysis, and review of estimate.
- Chapter 6: Provide information on how to document the cost estimates of remedial action alternatives developed during the FS, including an example cost summary.
- Chapter 7: Provide a list of references used in the document.
- Appendix A: Provide a list of government and non-government resources on the Internet that can be used to help develop remedial alternative cost estimates during the FS.
- Appendix B: Provide information on how to adjust costs for geographic location, escalation, and for impacts of health and safety requirements on productivity.
- Appendix C: Provide example templates for cost estimate summaries and backup information.
- Appendix D: Provide a glossary of key terms used in the document.

Rules of thumb for cost estimating during the FS, identified by the  symbol, are highlighted periodically within the document text. These rules of thumb, many of which provide typical cost percentages, are based on engineering judgement and not on detailed analysis of historical cost data. Also, highlight boxes throughout the document provide information on topics that are important, but not necessarily central to the discussion at hand. Web site addresses cited in the document were current at the time of publication.

Chapter Two
Background

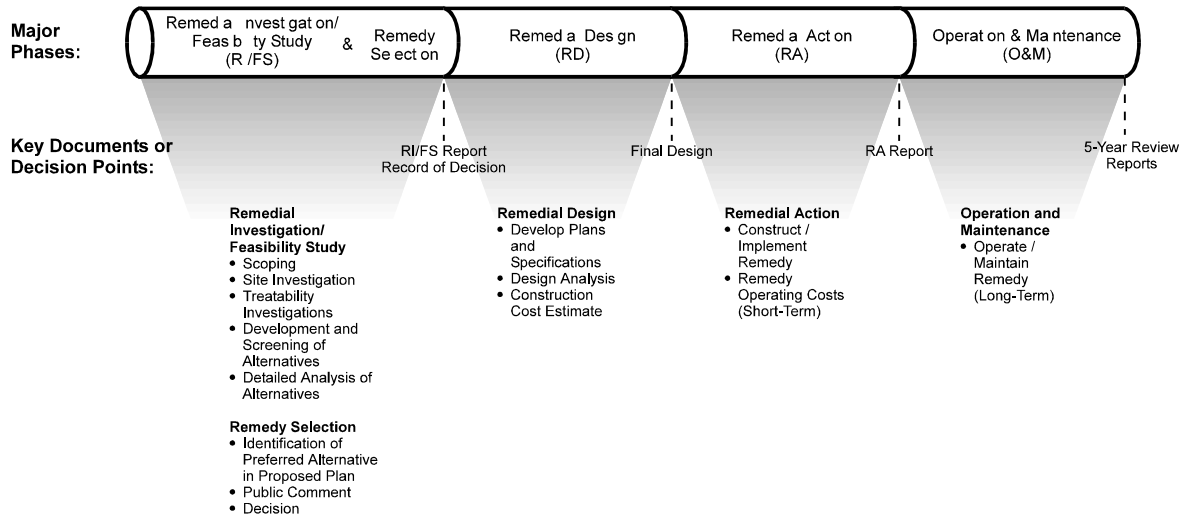
Estimating the cost of remedial action alternatives during the FS requires a basic understanding of applicable regulatory and cost engineering concepts. Therefore, this chapter provides background information on these subjects, including an overview of the Superfund process, discussion of the role of project definition in cost estimates, cost estimating within the Superfund process, and cost estimating during the FS.

2.1 Overview of Superfund Process

The Superfund "pipeline" (Exhibit 2-1) illustrates the major phases and decision points of the Superfund remedial response program.

The RI/FS process is used to gather the information necessary to select a remedy that will meet the statutory and regulatory requirements of the Superfund cleanup program. The remedial investigation (RI) includes sampling and analysis to characterize the nature and extent of contamination; baseline risk assessment to assess current and potential future risks to human health and the environment; and treatability studies, as appropriate, to evaluate the effectiveness of treatment or recovery technologies to reduce the toxicity, mobility, or volume of hazardous substances or contaminated media.

The FS consists of two main phases: (1) development and screening of remedial action alternatives; and (2) comparison of each alternative that passes screening in a detailed analysis. A range of remedial action alternatives is developed during the FS as data become available from the RI site characterization, with treatability studies helping to reduce uncertainties concerning cost and performance of treatment alternatives.



For Further Information

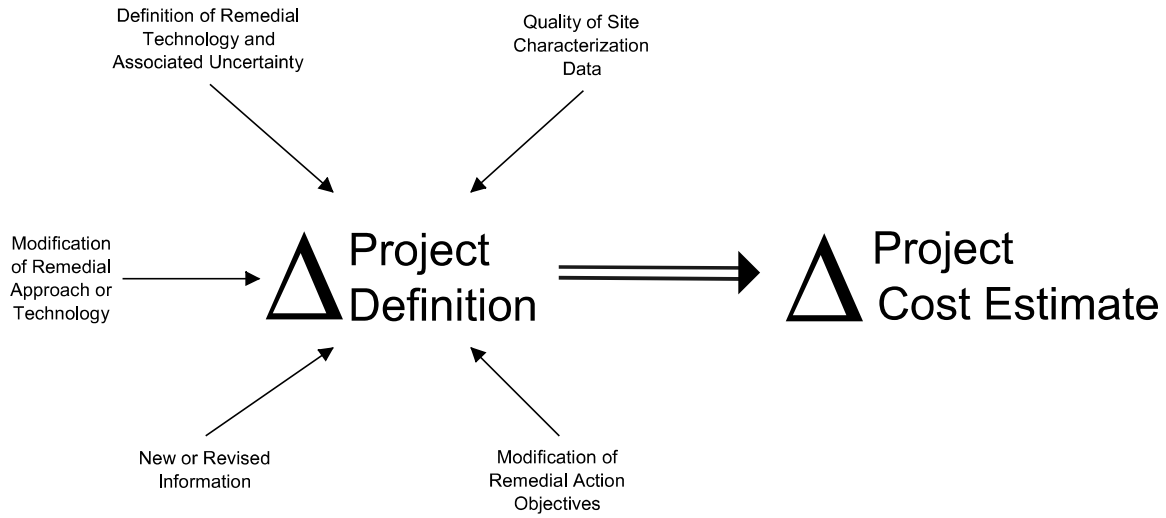
For further information on the Superfund remedy selection process, see the following publications:

- National Oil and Hazardous Substances Pollution Contingency Plan (NCP), Subpart E - Hazardous Substance Response, Section 300.430 – Remedial Investigation/ Feasibility Study and Selection of Remedy (40 CFR Part 300) (*http://www.epa.gov/docs/epacfr40/chapt-I.info/subch-J/*)
- Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA, Interim Final (USEPA 1988)
- A Guide to Selecting Superfund Remedial Actions (USEPA 1990)
- The Role of Cost in the Superfund Remedy Selection Process (USEPA 1996) (*http://www.epa.gov/superfund/resources/cost_dir/index.htm*)
- Rules of Thumb for Superfund Remedy Selection (USEPA 1997) (*http://www.epa.gov/superfund/resources/rules/index.htm*)
- A Guide to Preparing Superfund Proposed Plans, Records of Decision, and Other Remedy Selection Decision Documents (USEPA 1999) (*http://www.epa.gov/superfund/resources/remedy/rods/index.htm*)

During remedy selection, a preferred alternative is identified, presented in a proposed plan, and documented in a ROD following evaluation of public comment.[1] Plans, specifications, and other documents necessary to construct or implement the remedy are developed during remedial design (RD). Remedial action (RA) is the actual implementation of the remedy. Operation and maintenance (O&M) is used to maintain the effectiveness of the remedial action. More information on the differences between the RA and O&M phases and how they relate to estimating the cost of remedial action alternatives is provided in Chapter 3.

Exhibit 2-1
The Superfund Pipeline

2.2 Role of Project Definition in Cost Estimates



The Association for the Advancement of Cost Engineering (AACE) International defines a cost estimate as "an evaluation of all the costs of the elements of a project or effort as defined by an agreed-upon scope" (AACE 1990). The total estimated cost of a project is primarily dependent on how well, or to what degree, the project is defined (i.e., "scope" or completeness of design).

---

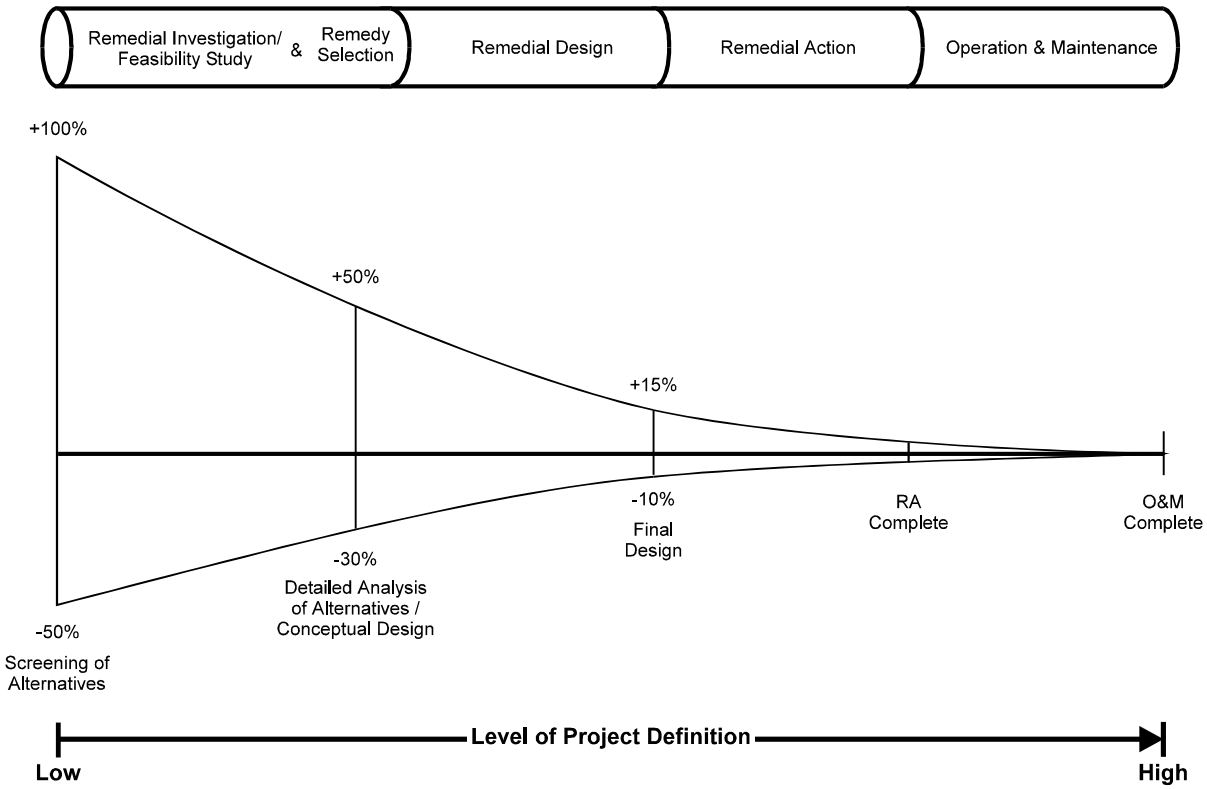
[1] Cost is one of nine criteria established by USEPA to guide remedy selection decision making and is a critical factor in the process of identifying a preferred remedy. In addition, CERCLA and the NCP require that every remedy selected must be cost-effective. See *The Role of Cost in the Superfund Remedy Selection Process* (USEPA 1996) for a more complete discussion.

A change (Δ) in project definition will result in a change (Δ) in the project cost estimate. This relationship, including factors that may affect a change in project definition and, therefore, a change in the cost estimate for a remedial action project, is illustrated in Exhibit 2-2.

Exhibit 2-2
Relationship of Project Definition to Cost Estimate for a Remedial Action Project

2.3 Cost Estimating During the Superfund Process

As a project moves from the planning stage into the design and implementation stage, the level of project definition increases, thus allowing for a more accurate cost estimate. An "early" estimate of the project's life cycle costs is made during the FS to make a remedy selection decision.[2]



At the FS stage, the design for the remedial action project is still conceptual, not detailed, and the cost estimate is considered to be "order-of-magnitude." The cost engineer must make assumptions about the detailed design in order to prepare the cost estimate. As a project progresses, the design becomes more complete and the cost estimate becomes more "definitive," thus increasing the accuracy of the cost estimate. This process is depicted in Exhibit 2-3 for remedial action projects in the Superfund program.[3]

---

[2] The term "life cycle cost" refers to the total project cost across the life span of a project, including design, construction, operation and maintenance, and closeout activities. The cost estimate developed during the FS is a projection of the life cycle cost of a remedial action project, not including the RI/FS or earlier phases.

[3] The accuracy range curves shown in Exhibit 2-3, representing both construction and operation costs, are for illustrative purposes only. The specific percentages correlate with generally accepted rules of thumb for cost estimating accuracy and are not meant to imply that these goals will be precisely achieved.

Exhibit 2-3
Expected Cost Estimate Accuracy Along the Superfund Pipeline

2.4 Cost Estimating During the Feasibility Study

During the FS, cost estimates are developed for each remedial action alternative for comparison purposes. The accuracy of these estimates is linked to the quality of the RI data, which helps define the scope of each alternative. Because the RI/FS cannot remove all uncertainty no matter how good the data may be, the expected accuracy of cost estimates during the FS is less than that of estimates developed during later stages of the Superfund process.

Cost estimates are developed at both the "screening of alternatives" and "detailed analysis of alternatives" phases of the FS, with expected accuracy ranges of –50 to +100 percent and –30 to +50 percent, respectively, as shown in Exhibit 2-3.[4] Cost estimates developed during these two phases are further described in the following paragraphs.

---

[4] If the number of viable alternatives developed during the FS process is limited, the "screening of alternatives" step is not always performed, nor is it required (Section 4.1.2.1 of RI/FS guidance [USEPA 1988]). However, the "detailed analysis of alternatives" is performed regardless to evaluate each alternative against the NCP evaluation criteria.

Screening of Alternatives

Screening-level cost estimates are used to screen out disproportionately expensive alternatives in determining what alternatives should be retained for detailed analysis. The National Oil and Hazardous Substances Contingency Plan (NCP) includes the following language in its description of the cost criterion for screening of alternatives:

> "The costs of construction and any long-term costs to operate and maintain the alternatives shall be considered." (40 CFR 300.430(e)(7)(iii))

Screening-level cost estimates should focus on relative accuracy in order to make comparative estimates so that decisions between alternatives can be appropriately considered as the accuracy of the cost estimates improves beyond the screening process. The procedures used to develop these estimates are similar to those used for the detailed analysis, except that alternatives are not as well refined and cost components are not as well developed. The screening-level accuracy range of –50 to +100 percent means that, for an estimate of $100,000, the actual cost of an alternative is expected to be between $50,000 and $200,000.

The basis for a screening-level cost estimate can include a variety of sources, including cost curves, generic unit costs, vendor information, standard cost estimating guides, historical cost data, and estimates for similar projects, as modified for the specific site. Both capital and O&M costs should be considered, where appropriate, at the screening level.

Direct and Indirect Cost Terminology

There may be some variability in the use of the terms "direct cost" and "indirect cost." This is due to a difference in perspective. To the "owner" of the project (e.g., government or potentially responsible party [PRP]), the "direct costs" of cleanup are the equipment, labor, and material costs necessary to construct the remedial action (including contractor markups, such as overhead and profit). From this perspective, the "indirect costs" are all other costs not part of the actual construction project but necessary to implement the remedial action (e.g., engineering, legal, construction management, and other technical and professional services). However, to the "implementor" of the project (e.g., construction contractor), the "direct costs" of cleanup are those costs that can be attributed to a single task of construction work, while the "indirect costs" are those that cannot be assigned to a specific activity (e.g., contractor markups).

Due to the potential for confusion caused by these differences in perspective, the specific terms "direct cost" and "indirect cost" are not used in the remainder of this guide. Rather, a distinction is made between costs associated with specific construction or O&M activities and costs for professional/technical services necessary to support those activities. Contractor markups would be included along with the labor, equipment, and material costs for specific construction or O&M activities. This terminology should avoid confusion, while still addressing both aspects of cost that are identified in the NCP for the Superfund remedy selection process.

Detailed Analysis of Alternatives

Cost estimates developed during the detailed analysis phase are used to compare alternatives and support remedy selection. The NCP includes the following language in its description of the cost criterion for the detailed analysis and remedy selection:

> "The types of costs that shall be assessed include the following: (1) Capital costs, including both direct and indirect costs (2) Annual operations and maintenance costs; and (3) Net present value of capital and O&M costs." (40 CFR 300.430 (e)(9)(iii)(G))

Remedial action alternative cost estimates for the detailed analysis are intended to provide a measure of total resource costs over time (i.e., "life cycle costs") associated with any given alternative.[5] As such, these estimates generally are based on more detailed information and should achieve a greater level of accuracy than screening-level estimates. The detailed analysis level accuracy range of –30 to +50 percent means that, for an estimate of $100,000, the actual cost of an alternative is expected to be between $70,000 and $150,000.

[5] These life cycle estimates should not include costs that would be incurred by the site owner or government independent of the remedial action (e.g., U.S. Department of Energy program management costs, unrelated facility or site maintenance costs). Nor should these estimates include other "external costs" not associated with the implementation of the remedial action (e.g., economic impacts to residents or businesses as a result of remediation activity).

Chapter Three
Capital and O&M Costs

The NCP states that the types of costs to be assessed in the FS include capital and annual O&M costs. This chapter provides definitions and checklists that can be used to identify capital and O&M costs for remedial action alternatives.

3.1 Definitions

Included under the general categories of capital and O&M costs identified in the NCP are capital, annual O&M, and periodic costs (capital or O&M), as defined below. These definitions are consistent with past USEPA guidance and do not change the intent of the NCP.

Capital Costs

Capital costs are those expenditures that are required to construct a remedial action. They are exclusive of costs required to operate or maintain the action throughout its lifetime. Capital costs consist primarily of expenditures initially incurred to build or install the remedial action (e.g., construction of a groundwater treatment system and related site work).

Capital costs include all labor, equipment, and material costs, including contractor markups such as overhead and profit, associated with activities such as mobilization/demobilization; monitoring; site work; installation of extraction, containment, or treatment systems; and disposal. Capital costs also include expenditures for professional/technical services that are necessary to support construction of the remedial action.

Annual O&M Costs

Operation and maintenance (O&M) costs are those post-construction costs necessary to ensure or verify the continued effectiveness of a remedial action. These costs are estimated mostly on an annual basis.

Annual O&M costs include all labor, equipment, and material costs, including contractor markups such as overhead and profit, associated with activities such as monitoring; operating and maintaining extraction, containment, or treatment systems; and disposal. Annual O&M costs also include expenditures for professional/technical services necessary to support O&M activities.

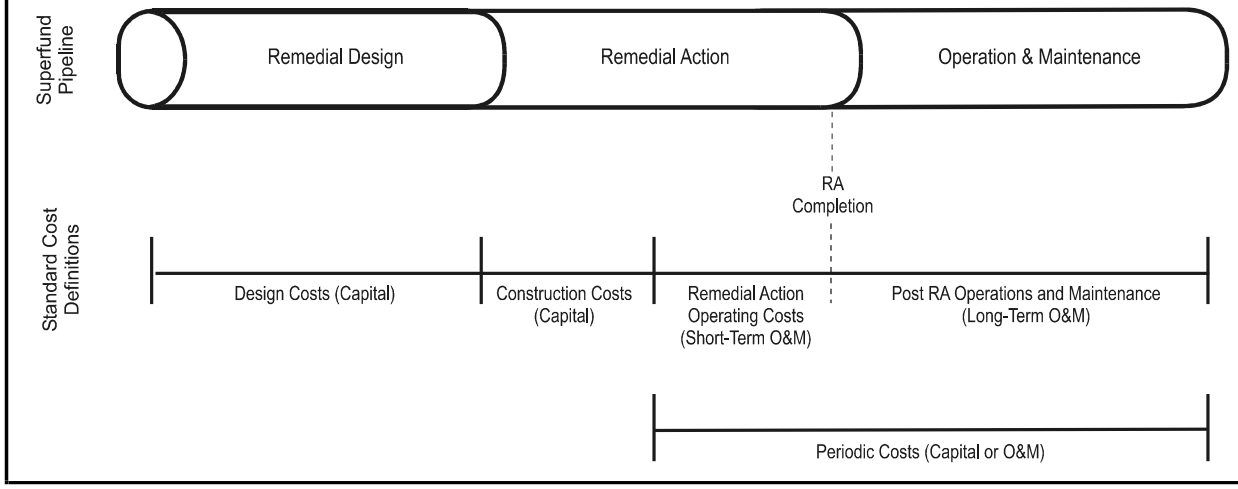
Periodic Costs

Periodic costs are those costs that occur only once every few years (e.g., five-year reviews, equipment replacement) or expenditures that occur only once during the entire O&M period or remedial timeframe (e.g., site closeout, remedy failure/replacement). These costs may be either capital or O&M costs, but because of their periodic nature, it is more practical to consider them separately from other capital or O&M costs in the estimating process.

3.2 Relationship of Capital and O&M Costs to Superfund Phases

A Superfund response action can occur in two phases: (1) remedial action and (2) O&M. In general, remedial action is defined by CERCLA to include activities required to prevent or mitigate the migration of contaminants into the environment. As such, a "remedial action" may not be complete when construction is complete, as in the case of a pump and treat remedy that may require many years of operation. In these cases, remedial action may include tasks that are traditionally considered to be O&M (see "Regulatory Definitions" to right for further explanation). Per CERCLA, O&M typically occurs after the remedial action has been completed and may include the tasks necessary to continue preventing or mitigating the migration of contaminants into the environment (e.g., long term surveillance and monitoring). Therefore, the RA phase of the Superfund pipeline can include both construction and short-term O&M activities, while the O&M phase consists primarily of long-term O&M (Exhibit 3-1).

Regulatory Definitions for RA and O&M



Under the Superfund program, O&M typically begins only after the remedial action has achieved remedial action objectives and remediation goals stated in the ROD and is determined to be operational and functional (40 CFR 300.435(f)(1)). A remedy becomes "operational and functional" normally within one year after construction is completed.

For Fund-financed remedial actions to treat or restore groundwater or surface water quality to a level protective of human health and the environment, the operation of the remedy is considered part of the remedial action phase for a period of up to 10 years after the remedial action becomes operational and functional (40 CFR 300.435(f)(3)). Activities necessary to maintain the effectiveness of the remedy past this period are considered to be O&M, thereby shifting financial responsibility from the Federal government to the government of the State in which the site is located.

For remedial alternative cost estimates developed during the FS, the conventional distinctions between capital and O&M costs should be used. As shown in Exhibit 3-1 on the "standard cost definitions" line, capital costs considered during the FS include design and construction while O&M costs include both short-term and long-term O&M. Periodic costs (e.g., replacement or repair costs, five-year review costs) can occur at any time during the O&M period (both short-term and long-term).

Exhibit 3-1

Relationship of Capital and O&M Costs to Superfund Phases

3.3 Cost Element Checklists

Checklists can be used to help evaluate capital and O&M costs for each remedial action alternative and to reduce the possible exclusion of key cost elements. A cost estimate generally will be more "complete" if as many cost elements as possible are accounted for, even though uncertainty may remain about their quantity or unit cost. Checklists also promote consistency between estimates.

Checklists are provided in Exhibits 3-2, 3-3, and 3-4 for capital, annual O&M, and periodic cost elements, respectively. The checklists are designed to be flexible, and by design, do not follow any standard work breakdown structure (WBS) or numbering system. The checklists are not all-inclusive and, therefore, the listed cost elements should not be assumed to apply to every remedial action alternative. Rather, the checklists can be used to identify applicable cost elements, which can be added to or modified as needed. Exhibits 3-2, 3-3, and 3-4 provide descriptions of cost elements, as well as example sub-elements.

Work Breakdown Structures

Cost estimates for Federal hazardous, toxic, or radioactive waste (HTRW) cleanup projects typically use a work breakdown structure (WBS) to identify cost elements. The Environmental Cost Engineering Committee (EC2), formerly known as the Interagency Cost Estimating Group (ICEG), has played a key role in WBS development. EC2 is comprised of cost professionals from the USEPA, U.S. Department of Energy (USDOE), U.S. Army Corps of Engineers (USACE), U.S. Navy, and U.S. Air Force. Several work breakdown structures have been developed, each of which can be useful for identifying potential cost elements to include in a remedial alternative FS cost estimate. These include:

- HTRW Remedial Action (RA) / Operation & Maintenance (O&M) WBS, February 1996 (*http://www.frtr.gov/cost/ec2/wbs1.html*)
- Phased Based HTRW WBS, April 1998 (*http://www.frtr.gov/cost/ec2/wbs2.html*)
- Environmental Cost Element Structure (ECES), September 1999 (*http://www.em.doe.gov/aceteam/eces.html*)

While the 1996 HTRW WBS (required by USACE) focuses on the RA and O&M phases, the ECES is more comprehensive and covers cost elements from initial studies through long term monitoring.

Capital Cost Elements

Capital cost elements from the checklist in Exhibit 3-2 are listed below:

Construction Activities

- Mobilization / Demobilization
- Monitoring, Sampling, Testing, and Analysis
- Site Work
- Surface Water Collection or Containment
- Groundwater Extraction or Containment
- Gas/Vapor Collection or Control
- Soil Excavation
- Sediment/Sludge Removal or Containment
- Demolition and Removal
- Cap or Cover
- On-Site Treatment (specify treatment technology)
- Off-Site Treatment / Disposal
- Contingency

Professional/Technical Services

- Project Management
- Remedial Design
- Construction Management

Institutional Controls

The elements listed as construction activities would be incurred as part of the physical construction of the remedial action. Contingency covers unknowns or unanticipated conditions associated with construction activities. Project management, remedial design, and construction management are professional/technical services to support construction of the remedial action. Institutional controls, which are legal or administrative measures used to limit or restrict site access or human exposure to contamination, can be a major component of a remedial alternative and therefore warrant separate consideration.

The terminology for each cost element should be made as alternative-specific as possible (i.e., terminology from the checklist should not necessarily be used directly). For example, "Sediment/Sludge Removal or Containment" could simply be "Contaminated Sludge Removal" if only removal of sludge, not sediment, is to occur. For on-site treatment, the applicable treatment technology (e.g., "Soil Vapor Extraction") should be specified (see "Example" to right).

Costs of construction activities are typically estimated on an element-by-element basis. Contractor markups such as overhead and profit should generally be included in these cost elements, rather than listed separately in the capital cost summary. Contingency is typically added as a percentage to the total cost of construction activities. Professional/technical services are typically estimated as a percentage of the total cost of construction activities plus contingency. A more detailed discussion of contingency is provided in Chapter 5. Institutional controls are typically estimated on an element-by-element basis. The development and documentation of capital costs are further described in Chapters 5 and 6, respectively.

Example Capital Cost Element Structure

An example of how capital cost elements and sub-elements might be structured for a remedial alternative that uses air sparging (AS), soil vapor extraction (SVE), and a passive treatment wall (i.e., permeable reactive barrier) to treat contaminated soil and groundwater is as follows:

- Mobilization/Demobilization
  - Construction Equipment
  - Submittals/Implementation Plans
  - Temporary Facilities & Utilities
  - Post-Construction Submittals
- Monitoring, Sampling, Testing, and Analysis
  - SVE Monitoring Wells
  - Treatment Wall Monitoring Wells
- Site Work
  - Clearing and Grubbing
  - Seeding/Mulch/Fertilizer
- Air Sparging / Soil Vapor Extraction
  - Mobilize SVE System
  - AS Injection Wells
  - AS Blower
  - AS Piping
  - SVE System
  - SVE Extraction Wells
  - SVE Piping
  - Electrical Hookup
  - Startup and Testing
- Passive Treatment Wall
  - Construct Slurry Trench
  - Install Reactive Media
- Off-Site Treatment/Disposal
  - Off-Site Transport of Soil Cuttings
  - Off-Site Disposal of Soil Cuttings
  - Wastewater Discharge/Testing
- Project Management
- Remedial Design
- Construction Management
- Institutional Controls
  - Institutional Controls Plan
  - Groundwater Use Restriction
  - Site Information Database

Exhibit 3-2
Capital Cost Element Checklist

Cost Element	Description	Example Sub-Elements
Construction Activities		
Mobilization/ Demobilization	Bringing equipment and personnel to the site (mobilization) or removing equipment and personnel (demobilization) for purposes of constructing or installing the remedial action. Includes setup/construction and/or removal of temporary facilities and utilities. Does not include mobilization or demobilization specific to constructing or installing an on-site treatment facility.	☐ Construction Equipment ☐ Submittals/Implementation Plans __ Air Monitoring Plan __ Construction Quality Control Plan __ Construction Schedule __ Environmental Protection Plan __ Materials Handling/Transportation/Disposal Plan __ Permits __ Sampling and Analysis Plan __ Site Safety and Health Plan __ Site Security Plan __ Site Work Plan __ Storm Water Pollution Prevention Plan __ Training & Medical Certifications ☐ Temporary Facilities __ Office Trailers __ Storage Facilities __ Security Fencing & Signs __ Roads and Parking __ Decontamination Facilities ☐ Temporary Utilities ☐ Temporary Relocation of Roads/Structures/Utilities ☐ Post-Construction Submittals __ As-Built Drawings __ O&M Manuals __ QA/QC Documentation ☐ Site Security Personnel ☐ _____ ☐ _____

Exhibit 3-2 (cont.)
Capital Cost Element Checklist

Cost Element	Description	Example Sub-Elements
Construction Activities (cont.)		
Monitoring, Sampling, Testing, and Analysis	Sampling, testing, on- or off-site analysis, data management, and quality assurance/ quality control. Includes monitoring to evaluate remedy performance and/or compliance with regulations.	☐ Meteorological Monitoring ☐ Air Monitoring and Sampling ☐ Radiation Monitoring ☐ Health and Safety Monitoring ☐ Personal Protective Equipment ☐ Monitoring Wells ☐ Geotechnical Instrumentation ☐ Soil Sampling ☐ Sediment Sampling ☐ Surface Water Sampling ☐ Groundwater Sampling ☐ Radioactive Waste Sampling ☐ Asbestos Sampling ☐ Laboratory Chemical Analysis ☐ On-Site Chemical Analysis ☐ Radioactive Waste Analysis ☐ Geotechnical Testing ☐ Chemical Data Management ☐ _____ ☐ _____
Site Work	Activities to establish the infrastructure necessary for the project (i.e., site preparation). Also includes permanent site improvements and restoration of areas or site features disturbed during site remediation. Site work is generally assumed to be "clean work," meaning that there is no contact with contaminated media or materials. Excludes all site work specific to constructing or installing an on-site treatment facility.	☐ Demolition ☐ Clearing and Grubbing ☐ Earthwork __ Stripping __ Stockpiling __ Excavation __ Borrow __ Grading __ Backfill __ Topsoil ☐ Roads/Parking/Curbs/Walks ☐ Vegetation and Planting __ Topsoil __ Seeding/Mulch/Fertilizer __ Sodding __ Erosion Control Fabric __ Shrubs/Trees/Ground Cover ☐ Fencing/Signs/Gates ☐ Utilities __ Electrical __ Telephone/Communications __ Water/Sewer/Gas ☐ Storm Drainage/Subdrainage ☐ Sediment Barriers ☐ _____ ☐ _____

Exhibit 3-2 (cont.)
Capital Cost Element Checklist

Cost Element	Description	Example Sub-Elements
Construction Activities (cont.)		
Surface Water Collection or Containment	Collection or containment of contaminated surface water. Excludes treatment, off-site transportation, or off-site treatment/ disposal of contaminated surface water.	☐ Pumping ☐ Draining ☐ Channel/Waterway ☐ Berm/Dike ☐ Lagoon/Basin/Tank ☐ _____ ☐ _____
Groundwater Extraction or Containment	Extraction or containment of contaminated groundwater. Excludes treatment, off-site transportation, or off-site treatment/disposal of contaminated groundwater.	☐ Extraction/Injection Well __ Vertical __ Horizontal ☐ Extraction Trench ☐ Pumps ☐ Piping ☐ Lagoon/Basin/Tank ☐ Subsurface Drains ☐ Subsurface Barrier __ Slurry Wall __ Grout Curtain __ Sheet Piling ☐ _____ ☐ _____
Gas/Vapor Collection / Control	Collection or control of off-gas or air emissions from contaminated sources.	☐ Collection Well System ☐ Collection Trench System ☐ Collection System at Lagoon Cover ☐ Fugitive Dust Control ☐ Vapor/Gas Emissions Control ☐ _____ ☐ _____
Soil Excavation	Excavation and handling of contaminated soil. Excludes treatment, off-site transportation, or off-site treatment/disposal of contaminated soil.	☐ Excavation ☐ Hauling ☐ Stockpiling ☐ _____ ☐ _____

Professional/Technical Services		
Project Management	Services to support construction or installation of remedial action not specific to remedial design or construction management.	☐ Planning ☐ Community Relations ☐ Bid/Contract Administration ☐ Cost and Performance Reporting ☐ Permitting ☐ Legal ☐ Construction Completion Report ☐ _____ ☐ _____
Remedial Design	Services to design the remedial action, including pre-design activities to collect the necessary data.	☐ Field Data Collection and Analysis ☐ Design Survey ☐ Treatability Study __ Bench-Scale __ Pilot-Scale __ Field-Scale ☐ Preliminary/Intermediate/Final Design __ Design Analysis __ Plans & Specifications __ Construction Cost Estimate __ Construction Schedule ☐ _____ ☐ _____
Construction Management	Services to manage construction or installation of remedial action, excluding any similar services provided as part of construction activities.	☐ Submittal Review ☐ Change Order Review ☐ Design Modifications ☐ Construction Observation ☐ Construction Survey ☐ Construction Schedule Tracking ☐ QA/QC Documentation ☐ O&M Manual ☐ Record Drawings ☐ _____ ☐ _____
Institutional Controls	Non-engineering (i.e., administrative or legal) measures to reduce or minimize potential for exposure to site contamination or hazards (i.e., limit site access or restrict site access).	☐ Institutional Controls Plan ☐ Restrictive Covenants ☐ Zoning ☐ Property Easements ☐ Deed Notice ☐ Advisories ☐ Groundwater Use Restrictions ☐ Site Information Database ☐ _____ ☐ _____

Annual O&M Cost Elements

Annual operation and maintenance cost elements from the checklist in Exhibit 3-3 are listed below:

O&M Activities

- Monitoring, Sampling, Testing, and Analysis
- Extraction, Containment, or Treatment Systems
- Off-Site Treatment / Disposal
- Contingency

Professional/Technical Services

- Project Management
- Technical Support

Institutional Controls

The elements listed as O&M activities are incurred as part of physical operation and maintenance activities. Contingency covers unknowns or unanticipated conditions. Project management and technical support are professional/technical services to support O&M activities. Institutional controls may require annual update or maintenance to ensure potential for exposure to site contamination or hazards is reduced or minimized.

As with capital costs, the terminology for each element should be made alternative-specific, as applicable (see "Example" above).

Example Annual O&M Cost Element Structure

An example of how annual O&M cost elements and sub-elements might be structured for a remedial alternative that uses air sparging (AS), soil vapor extraction (SVE), and a passive treatment wall to treat contaminated soil and groundwater is as follows:

- Performance Monitoring
  - SVE Vapor Monitoring
  - SVE Emissions Monitoring
  - Treatment Wall – Groundwater Sampling
  - Treatment Wall – Groundwater Analysis
- Site Monitoring
  - Groundwater Sampling
  - Groundwater Laboratory Analysis
- Air Sparging / Soil Vapor Extraction
  - Operations Labor
  - Maintenance Labor
  - Equipment Repair
  - Utilities
- Off-Site Treatment/Disposal
  - Wastewater Discharge/Testing
- Project Management
- Technical Support
- Institutional Controls
  - Site Information Database

Annual O&M costs can vary and may be estimated for different time periods, depending on the operating conditions and requirements. For example, the first five years of a groundwater monitoring program may require semiannual sampling, while the next twenty years may only require annual sampling. Likewise, an installed cap or cover may require more frequent inspections during the first year of O&M than during subsequent years.

Costs of O&M activities are typically estimated on an element-by-element basis. Contractor markups such as overhead and profit should generally be included in these cost elements, rather than listed separately. Contingency (Chapter 5) is typically added as a percentage to the total cost of O&M activities. Professional/technical services are typically estimated as a percentage of the total cost of O&M activities plus contingency. Chapters 5 and 6 provide more information on development and documentation of annual O&M costs.

Exhibit 3-3
Annual O&M Cost Element Checklist

Cost Element	Description	Example Sub-Elements
O&M Activities		
Monitoring, Sampling, Testing, and Analysis[1]	Sampling, testing, on- or off-site analysis, data management, and quality assurance/quality control during the O&M period. Can include monitoring to evaluate remedy performance, compliance with regulations, or monitoring to track migration of contaminant plume.	☐ Meteorological Monitoring ☐ Air Monitoring and Sampling ☐ Radiation Monitoring ☐ Health and Safety Monitoring ☐ Personal Protective Equipment ☐ Monitoring Wells ☐ Soil Sampling ☐ Sediment Sampling ☐ Surface Water Sampling ☐ Groundwater Sampling ☐ Process Water Sampling ☐ Process Air Sampling ☐ Laboratory Chemical Analysis ☐ On-Site Chemical Analysis ☐ Chemical Data Management ☐ _____ ☐ _____
Extraction, Containment, or Treatment Systems[2]	Operation and maintenance of on-site systems to extract, contain, or treat contaminated media (e.g., soil, sediment, sludge, surface water, groundwater).	☐ Operations Labor ☐ Maintenance Labor ☐ Equipment Upgrade/Replacement/Repair ☐ Spare Parts ☐ Equipment Ownership/Rental/Lease ☐ Consumable Supplies ☐ Bulk Chemicals ☐ Raw/Process Materials ☐ Utilities ☐ _____ ☐ _____

[1] Site monitoring, performance monitoring, or compliance monitoring.

[2] Specify extraction, containment, or treatment system. Examples include groundwater extraction system, engineered cap or cover, soil vapor extraction system, groundwater treatment facility, etc. More than one system may be associated with an individual alternative.

Exhibit 3-3 (cont.)

Cost Element	Description	Example Sub-Elements
O&M Activities (cont.)		
Off-Site Treatment / Disposal	Treatment and/or disposal of wastes generated during operation and maintenance (e.g., on-site treatment residuals, monitoring wastes) at off-site commercial facilities, such as solid or hazardous waste landfills and incinerators.	☐ Material Handling/Loading ☐ Transportation to Off-Site Facility ☐ Treatment/Disposal Fees ☐ _____ ☐ _____
Contingency	Costs to cover unknowns, unforeseen circumstances, or unanticipated conditions associated with annual O&M of the remedial action.	☐ Scope Contingency ☐ Bid Contingency
Professional/Technical Services		
Project Management	Services to manage O&M activities not specific to technical support listed below.	☐ Planning ☐ Community Relations ☐ Cost and Performance Reporting ☐ Permitting ☐ Legal ☐ _____ ☐ _____
Technical Support	Services to monitor, evaluate, and report progress of remedial action.	☐ O&M Manual Updates ☐ O&M Oversight ☐ Progress Reports ☐ _____ ☐ _____
Institutional Controls	Annual update or maintenance of non-engineering measures to reduce or minimize potential for exposure to site contamination or hazards.	☐ Institutional Controls Plan ☐ Restrictive Covenants ☐ Zoning ☐ Property Easements ☐ Deed Notice ☐ Advisories ☐ Groundwater Use Restrictions ☐ Site Information Database ☐ _____ ☐ _____

Periodic Cost Elements

Periodic cost elements from the checklist in Exhibit 3-4 are listed below:

Construction / O&M Activities

- Remedy Failure or Replacement
- Demobilization of On-Site Extraction, Containment, or Treatment Systems
- Contingency

Professional/Technical Services

- Five Year Reviews
- Groundwater Performance and Optimization Study
- Remedial Action Report

Institutional Controls

Example Periodic Cost Element Structure

An example of periodic cost elements and sub-elements that might apply for a remedial alternative that uses air sparging (AS), soil vapor extraction (SVE), and a passive treatment wall is as follows:

- Five Year Reviews
- Demobilization of AS/SVE System
- Well Abandonment
- Remedial Action Report
- Update Institutional Controls Plan

Contingency is typically applied to the total of construction/O&M activities cost elements for the year in which they occur. Professional/technical services are typically estimated on an element-by-element basis, rather than as a percentage, for periodic costs. Chapters 5 and 6 provide more information on development and documentation of periodic costs.

Exhibit 3-4
Periodic Cost Element Checklist

Cost Element	Description	Example Sub-Elements
Construction/O&M Activities		
Remedy Failure or Replacement	Construction activity to replace an installed remedy or key components of the remedy.	☐ Mobilization/Demobilization ☐ Site Work ☐ Structures ☐ Process Equipment and Appurtenances ☐ Non-Process Equipment ☐ Startup and Testing ☐ _____ ☐ _____
Demobilization of On-Site Extraction, Containment, or Treatment Systems[1]	Construction activity to dismantle or take down extraction, containment, or treatment facilities or equipment upon completion of remedial action.	☐ Demolition and Removal ☐ Well Abandonment ☐ _____ ☐ _____
Contingency	Costs to cover unknowns, unforeseen circumstances, or unanticipated conditions associated with construction/O&M activities.	☐ Scope Contingency ☐ Bid Contingency
Professional/Technical Services		
Five Year Reviews	Services to prepare five-year review reports (if hazardous substances, pollutants, or contaminants remain on-site above levels that allow for unrestricted use and unlimited exposure).	☐ Site Visit ☐ Field Data Collection ☐ Data Review and Analysis ☐ Report Preparation ☐ _____ ☐ _____
Groundwater Performance and Optimization Study	Services to analyze and optimize on-going groundwater pump and treat systems.	☐ Site Visit ☐ Field Data Collection ☐ Data Review and Analysis ☐ Report Preparation ☐ _____ ☐ _____

[1] Specify extraction, containment, or treatment system. Examples include groundwater extraction system, soil vapor extraction system, groundwater treatment facility, etc. More than one system may be associated with an individual alternative.

Professional/Technical Services (cont.)		
Remedial Action Report	Services to prepare remedial action report upon completion of remedial action.	☐ Site Visit ☐ Field Data Collection ☐ Data Review and Analysis ☐ Report Preparation ☐ _____ ☐ _____
Institutional Controls	Periodic update or maintenance of non-engineering measures to reduce or minimize potential for exposure to site contamination or hazards.	☐ Institutional Controls Plan ☐ Restrictive Covenants ☐ Zoning ☐ Property Easements ☐ Deed Notice ☐ Advisories ☐ Groundwater Use Restrictions ☐ Site Information Database ☐ _____ ☐ _____

Chapter Four
Present Value Analysis

Remedial action projects typically involve construction costs that are expended at the beginning of a project (e.g., capital costs) and costs in subsequent years that are required to implement and maintain the remedy after the initial construction period (e.g., annual O&M costs, periodic costs). Present value analysis is a method to evaluate expenditures, either capital or O&M, which occur over different time periods. This standard methodology allows for cost comparisons of different remedial alternatives on the basis of a single cost figure for each alternative. This single number, referred to as the present value, is the amount needed to be set aside at the initial point in time (base year) to assure that funds will be available in the future as they are needed, assuming certain economic conditions (see "Present Value Basics" to right).[1]

A present value analysis of a remedial alternative involves four basic steps:

1. Define the period of analysis.
2. Calculate the cash outflows (payments) for each year of the project.
3. Select a discount rate to use in the present value calculation.
4. Calculate the present value.

The following chapter sections describe the general requirements for each of these steps.

Present Value Basics

The present value (PV) of a future payment is calculated using the following equation:

$$PV = \frac{x_t}{(1+i)^t}$$

where x_t is the payment in year t (t = 0 for present or base year) and i is the discount rate. For example, suppose one needs to make a $1,000 payment in Year 5. Using a discount rate of 5%, the present value would be:

$$= \frac{\$1{,}000}{(1+0.05)^5} = \$783$$

Therefore, $783 would need to be set aside or invested in Year 0, at a discount or interest rate of 5%, in order to have $1,000 in Year 5.

For a stream or series of future payments, the total present value from 1 to n years would be calculated as:

$$PV_{total} = \sum_{t=1}^{t=n} \frac{x_t}{(1+i)^t}$$

If a $1,000 payment is needed for each of the next five years, then the total present value of these payments, at a discount rate of 5%, would be:

$$= \sum_{t=1}^{t=5} \frac{\$1{,}000}{(1+0.05)^t} = \$4{,}329$$

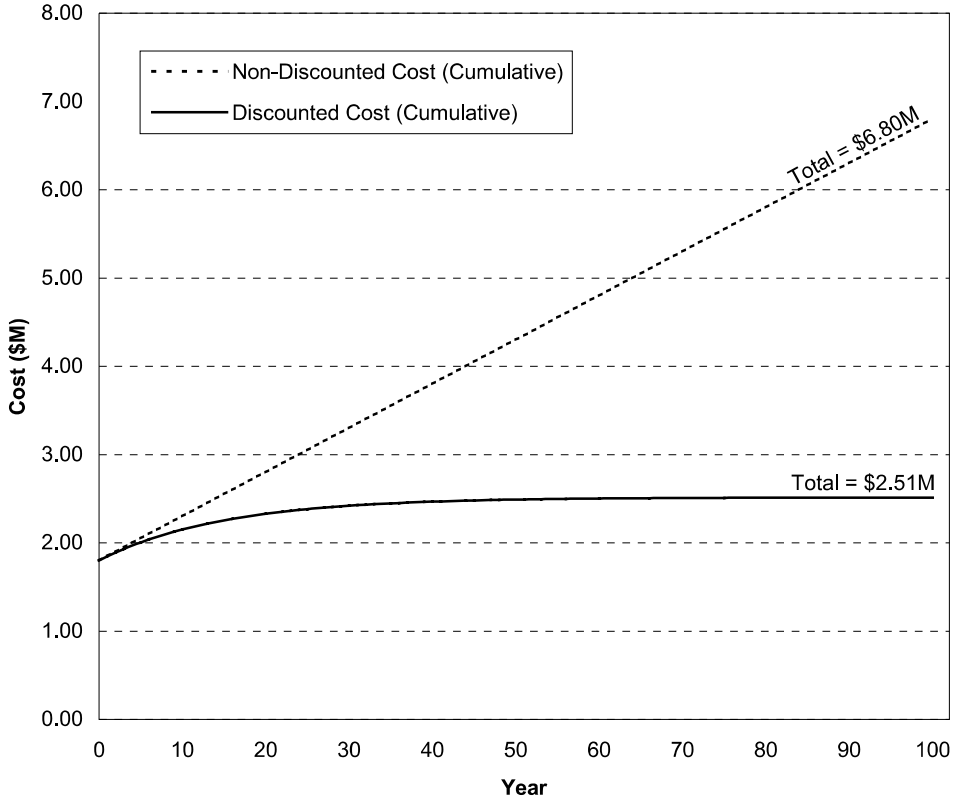
Therefore, $4,329 would need to be set aside in Year 0 to make a $1,000 payment in each of the next five years.

4.1 Define the Period of Analysis

The period of analysis is the period of time over which present value is calculated. In general, the period of analysis should be

[1] This guide uses primarily "present value," although "net present value" and "present worth" are other commonly used terms.

equivalent to the project duration, resulting in a complete life cycle cost estimate for implementing the remedial alternative. The project duration generally begins with the planning, design, and construction of the remedial alternative, continues through short- and long-term O&M, and ends with project completion and closeout. Each remedial alternative may have a different project duration. For example, one alternative may have a two-year construction period and no future O&M. Another alternative may have no construction period and many years of O&M.



Past USEPA guidance recommended the general use of a 30-year period of analysis for estimating present value costs of remedial alternatives during the FS (USEPA 1988). While this may be appropriate in some circumstances, and is a commonly made simplifying assumption, the blanket use of a 30-year period of analysis is not recommended. Site-specific justification should be provided for the period of analysis selected, especially when the project duration (i.e., time required for design, construction, O&M, and closeout) exceeds the selected period of analysis.[2]

For long-term projects (e.g., project duration exceeding 30 years), it is recommended that the present value analysis include a "no discounting" scenario. A non-discounted constant dollar cash flow over time demonstrates the impact of a discount rate on the total present value cost and the relative amounts of future annual expenditures. Non-discounted constant dollar costs are presented for comparison purposes only and should not be used in place of present value costs in the Superfund remedy selection process. Exhibit 4-1 illustrates the impact of discounting for an example with a $1,800,000 initial capital cost and a $50,000 annual O&M cost spread out over 100 years at a discount rate of 7 percent. Section 4.4 provides more information on how the period of analysis is used in calculating present value.

The period of present value analysis should not necessarily be limited to the commonly-used assumption of 30 years. Explanation should be provided whenever the period of analysis is less than the estimated project duration.

[2] For example, a radioactive waste containment facility may require a 10,000-year design life (i.e., project duration) in order to protect human health and the environment, but the period of analysis for the cost estimate may be bounded at 1,000 years for calculation purposes.

Exhibit 4-1
Non-Discounted vs. Discounted Costs for an Example Project with a 100 Year Duration

4.2 Calculate Annual Cash Outflows

The second step of the present value analysis is to add up the capital and O&M cash outflows for each year of the project (i.e., annual cash outflow). These include capital costs to construct the remedial alternative, annual O&M costs to operate and maintain the remedial alternative over its planned life, and periodic costs for those capital or O&M costs that occur only once every few years. Usually, most or all of the capital costs are expended during the construction and startup of the project, before annual O&M begins. Although the present value of periodic costs is small for those that occur near the end of the project duration (e.g., closeout costs), these costs should be included in the present value analysis. See Chapter 3 for a complete discussion of capital and O&M cost elements for which annual cash outflows should be calculated.

Most FS cost analyses begin with a simplifying assumption that the duration of initial construction and startup will be less than one year (i.e., construction work will occur in "year zero" of the project). This "year zero" assumption can be modified if a preliminary project schedule has been developed and it is known that capital construction costs will be expended beyond one year.

☝ ***For FS present value analyses, most capital costs are assumed to occur in Year 0.***

Annual cash outflows for FS present value analyses should be estimated in constant dollars, denominated in terms of the base year (i.e., Year 0). Constant dollars, also called "real dollars," are not affected by general price inflation (i.e., they represent "units of stable purchasing power"). Thus, the cost of a particular good or service would be the same in Year 0, Year 1, Year 2, etc.

- ***Constant dollars, or "real dollars," are used for the present value analysis (i.e., no adjustment is made for inflation).***

The results of this step in the present value analysis should be an array of all costs in constant dollars for each year of the project, as shown by the example in Exhibit 4-2.

Exhibit 4-2
Example Array of Constant Dollar Costs for Present Value Analysis

Year	Capital Costs ($)	Annual O&M Costs ($)	Periodic Costs ($)	Total Cost ($)
0	1,800,000	0	0	1,800,000
1	0	50,000	0	50,000
2	0	50,000	0	50,000
3	0	50,000	0	50,000
4	0	50,000	0	50,000
5	0	50,000	10,000	60,000
6	0	50,000	0	50,000
7	0	50,000	0	50,000
8	0	50,000	0	50,000
9	0	50,000	0	50,000
10	0	50,000	50,000	100,000

4.3 Select a Discount Rate

The third step in the present value analysis is to select a discount rate. A discount rate, which is similar to an interest rate, is used to account for the time value of money. A dollar is worth more today than in the future because, if invested in an alternative use today, the dollar could earn a return (i.e., interest). Thus, discounting reflects the productivity of capital. If the capital were not employed in a specific use, it would have productive value in alternative uses. The choice of a discount rate is important because the selected rate directly impacts the present value of a cost estimate, which is then used in making a remedy selection decision. The higher the discount rate, the lower the present value of the cost estimate.

USEPA policy on the use of discount rates for RI/FS cost analyses is stated in the preamble to the NCP (55 FR 8722) and in Office of Solid Waste and Emergency Response (OSWER) Directive 9355.3-20 entitled "*Revisions to OMB Circular A-94 on Guidelines and Discount Rates for Benefit-Cost Analysis*" (USEPA 1993). Based on the NCP and this directive, a discount rate of 7% should be used in developing present value cost estimates for remedial action alternatives during the FS. This specified rate of 7% represents a "real" discount rate in that it approximates the marginal pretax rate of return on an average investment in the

private sector in recent years and has been adjusted to eliminate the effect of expected inflation. Therefore, this rate should be used with "constant" or "real" dollars that have not been adjusted for inflation (i.e., a dollar spent in future years is worth the same as a dollar spent in the present year), which is the typical situation for RI/FS cost analyses.

The 7% discount rate was established through an economic analysis performed by the Office of Management and Budget (OMB). USEPA's policy regarding the use of discount rates in present value calculations performed during the FS will be reevaluated periodically or when OMB updates Circular A-94.[3] Any changes to this policy will be contained in an update of OSWER Directive 9355.3-20, which can be found at *http://www.epa.gov/superfund/*.

OMB Circular A-94

The Office of Management and Budget (OMB) Circular A-94, *Guidelines and Discount Rates for Benefit-Cost Analyses of Federal Programs,* provides guidance for the use of discount rates in economic analyses performed by the Federal government. The circular is available at *http://www.whitehouse.gov/OMB/circulars/a094/a094.html* or by contacting the OMB publications office at (202) 395-7332.

Appendix C of OMB Circular A-94, which contains discount rates that may be applicable to Federal facility sites, is updated annually in January/February.

There may be circumstances in which it would be appropriate to consider the use of a lower or higher discount rate than 7% for the FS present value analysis. If a different discount rate is selected for the analysis, a specific explanation should be provided. For cost estimates that have large future year expenditures or where the discount rate assumption is a sensitive cost factor, a sensitivity analysis can be performed to evaluate the impacts of the discount rate assumption on the present value cost. See Chapter 5 for a more complete discussion of sensitivity analyses.

For Federal facility sites being cleaned up using Superfund authority, it is generally appropriate to apply the real discount rates found in Appendix C of OMB Circular A-94. These rates, which are also used in the President's annual budget submission to Congress, are based on interest rates from Treasury notes and bonds. Because the Federal government has a different "cost of capital" than the private sector, these rates are appropriate to use for adjusting future year expenditures in a present value calculation for Federal facility remediation projects. Although an analogous situation exists for Federal-lead sites that will be cleaned up by USEPA using the Superfund trust fund (i.e., Fund-lead sites), there is always a chance that the site will actually be remediated by a private, or "potentially-responsible," party (i.e., PRP-lead cleanup). Therefore, the 7% discount rate should generally be used in calculating net present value costs for all non-Federal facility sites.

A real discount rate of 7 percent should generally be used for all non-Federal facility sites. Real discount rates from Appendix C of OMB Circular A-94 should generally be used for all Federal facility sites.

---

[3] Appendix C of OMB Circular A-94 is updated on an annual basis around the time of the President's budget submission to Congress (i.e., January/February timeframe). However, the 7% discount rate contained in the main portion of the circular is not updated on an annual basis.

For FS cost analyses, the same discount rate should be used in evaluating all remedial alternatives for a site, even if the period of analysis differs from one to another. Exhibit 4-3 shows a present value comparison of six remedial alternatives with varying amounts of initial capital costs, annual O&M costs, and years of analysis. Alternative F has the second highest total cost in base year dollars, but the lowest present value cost. This is because much of its total costs are in the future, which become quite small after the discount rate is applied. The cost of Alternative C is less than that of alternative D, but its present value is higher, since it has large upfront capital costs. This example illustrates the effect of varying initial capital cost, annual O&M costs, and period of analysis on the present value cost of alternatives.

The same discount rate should be used for all remedial alternatives, even if the period of analysis varies from one to another.

Exhibit 4-3
Comparison of Present Value of Six Remedial Alternatives

Remedial Alternative	Initial Capital Cost ($000)	Annual O&M Cost ($000)	Period of Analysis* (Years)	Total Cost ($000)	Present Value at 7% ($000)
Alternative A	0	0	0	0	0
Alternative B	3,650	583	15	12,400	8,960
Alternative C	10,800	548	30	27,200	17,600
Alternative D	2,850	696	50	37,700	12,500
Alternative E	5,500	230	80	23,900	8,770
Alternative F	2,000	120	220	28,400	3,710

* In this example, the period of analysis is the same as project duration.

4.4 Calculate the Present Value

The last step is to calculate the present value. The present value of a remedial alternative represents the sum of the present values of all future payments associated with the project. For example, if the project will entail capital and O&M costs each year for 12 years, the present value is the sum of the present values of each of the 12 payments, or expenditures.

The present value of a future payment is the actual value that will be disbursed, discounted at an appropriate rate of interest. Present value for payment x_t in year t at a discount rate of i is calculated as follows:

$$PV = \frac{1}{(1+i)^t} \cdot x_t$$

The first operand in this equation, $1/(1+i)^t$, can be referred to as a "discount factor." Exhibit 4-4 provides annual discount factors at a rate of 7% for up to 200 years. Exhibit 4-5 illustrates the use of these factors for a remedial alternative with construction costs of $1,800,000 in Year 0, annual O&M costs of $50,000 for ten years, and periodic costs of $10,000 in Years 5 and 10 and $40,000 in Year 10.[4]

Exhibit 4-4
Annual Discount Factors at 7%

Year	Factor	Year	Factor	Year	Factor	Year	Factor	Year	Factor
1	0.935	23	0.211	45	0.0476	67	0.0107	89	0.00243

18	0.296	40	0.0668	62	0.0151	84	0.00340	160	0.0000199
19	0.277	41	0.0624	63	0.0141	85	0.00318	170	0.0000101
20	0.258	42	0.0583	64	0.0132	86	0.00297	180	0.00000514
21	0.242	43	0.0545	65	0.0123	87	0.00278	190	0.00000261
22	0.226	44	0.0509	66	0.0115	88	0.00260	200	0.00000133

Annual discount factor $= \frac{1}{(1+i)^t}$ where i = 0.07 and t = year (i.e., the present value of one dollar paid in year t at 7%)

[4] For present value analyses during the FS, distinction is generally not made as to what time of the year the total cost for each year is incurred (e.g., beginning, middle, or end). This simplifying assumption would not necessarily be used for budgeting purposes, but is appropriate for FS cost estimating purposes.

Exhibit 4-5
Example Present Value Calculation for a Remedial Alternative

Year	Capital Costs ($)	Annual O&M Costs ($)	Periodic Costs ($)	Total Cost ($)	Discount Factor at 7%	Total Present Value Cost at 7% ($)
0	1,800,000	0	0	1,800,000	1.000	1,800,000
1	0	50,000	0	50,000	0.935	46,800
2	0	50,000	0	50,000	0.873	43,700
3	0	50,000	0	50,000	0.816	40,800
4	0	50,000	0	50,000	0.763	38,200
5	0	50,000	10,000	60,000	0.713	42,800
6	0	50,000	0	50,000	0.666	33,300
7	0	50,000	0	50,000	0.623	31,200
8	0	50,000	0	50,000	0.582	29,100
9	0	50,000	0	50,000	0.544	27,200
10	0	50,000	50,000	100,000	0.508	50,800
Total	1,800,000	560,000		2,360,000	-	2,180,000

For a stream or series of payments from 1 to *n* years, the total present value is:

$$PV_{total} = \sum_{t=1}^{t=n} \frac{1}{(1+i)^t} \cdot x_t$$

When the annual cost, x_t, is constant over a period of years, beginning at Year 1, the calculations can be simplified by using a multi-year discount factor, which is the sum of the first operand in the above equation. Exhibit 4-6 provides multi-year discount factors at a rate of 7% for up to 200 years, as well as the formula to calculate multi-year discount factors at discount rates other than 7%. For example, the factor for 30 years at 7% is 12.409. Thus, the present value of $1,000 per year for 30 years is $1,000 x 12.409 = $12,400.

Exhibit 4-6
Multi-Year Discount Factors at 7%

Years	Factor	Years	Factor	Years	Factor	Years	Factor
1	0.935	29	12.278	57	13.984	85	14.240
2	1.808	30	12.409	58	14.003	86	14.243
3	2.624	31	12.532	59	14.022	87	14.246
4	3.387	32	12.647	60	14.039	88	14.249
5	4.100	33	12.754	61	14.055	89	14.251
6	4.767	34	12.854	62	14.070	90	14.253
7	5.389	35	12.948	63	14.084	91	14.255
8	5.971	36	13.035	64	14.098	92	14.257
9	6.515	37	13.117	65	14.110	93	14.259
10	7.024	38	13.193	66	14.121	94	14.261
11	7.499	39	13.265	67	14.132	95	14.263
12	7.943	40	13.332	68	14.142	96	14.264
13	8.358	41	13.394	69	14.152	97	14.266
14	8.745	42	13.452	70	14.160	98	14.267
15	9.108	43	13.507	71	14.169	99	14.268
16	9.447	44	13.558	72	14.176	100	14.269
17	9.763	45	13.606	73	14.183	110	14.277
18	10.059	46	13.650	74	14.190	120	14.281
19	10.336	47	13.692	75	14.196	130	14.284
20	10.594	48	13.730	76	14.202	140	14.285
21	10.836	49	13.767	77	14.208	150	14.285
22	11.061	50	13.801	78	14.213	160	14.285
23	11.272	51	13.832	79	14.218	170	14.286
24	11.469	52	13.862	80	14.222	180	14.286
25	11.654	53	13.890	81	14.226	190	14.286
26	11.826	54	13.916	82	14.230	200	14.286
27	11.987	55	13.940	83	14.234		
28	12.137	56	13.963	84	14.237		

Multi-year discount factor $= \sum_{t=1}^{t=n} \frac{1}{(1+i)^t} = \frac{(1+i)^n - 1}{i(1+i)^n}$, where i = 0.07, t = year, and n = total years

(i.e., the present value of one dollar paid per year from 1 to *n* years at 7%)

NOTE: These factors only apply when annual costs are constant.

Multi-year factors shown in Exhibit 4-6 cannot be used when periodic costs are added to the annual O&M cost for the years in which they occur. In cases like these, when future expenditures are not constant from year to year, discount factors taken from Exhibit 4-4 (or other list of factors if 7% is not used) should be applied to each future year's expenditure to convert into present value.

As Exhibits 4-4 and 4-6 indicate, discounted values of even large costs incurred far in the future tend to be negligible. For example, for a 200-year project with constant annual costs of $500,000 at 7%, 99.9% of the discounted O&M costs are incurred in the first 100 years, 97% in the first 50 years, and 88% in the first 30 years. The period of present value analysis, however, should not be shortened to less than the project duration (Section 4.1), particularly when O&M costs are significant, or when major costs, such as replacement or corrective maintenance, are expected to occur in the future. In addition, evaluation of a "no discounting" scenario would be recommended pursuant to discussion in Section 4.1.

In addition to calculating discount factors as shown in Exhibits 4-4 and 4-6, present value can be calculated using functions found in many spreadsheet software programs. For example, the PV function in Excel can be used to calculate the present value of a series of future payments by providing the interest rate, total number of payments, and payment made each period. When using spreadsheet functions or formulas, it is important that calculations be independently checked to ensure that the functions are being applied correctly.

Chapter Five
How to Develop the Cost Estimate

This chapter presents steps to develop a basic cost estimate for a remedial alternative during the FS. Although a variety of estimating methods or tools may be utilized, these steps follow a general activity-based approach, where the cost estimate is divided into discrete, quantifiable activities or elements for each alternative. The steps are as follows:

1. Describe the alternative.
2. Identify the cost element structure for capital, annual O&M, and periodic costs.
3. Estimate construction/O&M activities costs.
4. Apply contingency.
5. Estimate professional/technical services costs.
6. Estimate institutional controls costs, if applicable.
7. Conduct present value analysis.
8. If appropriate, conduct a sensitivity analysis.
9. Review estimate.

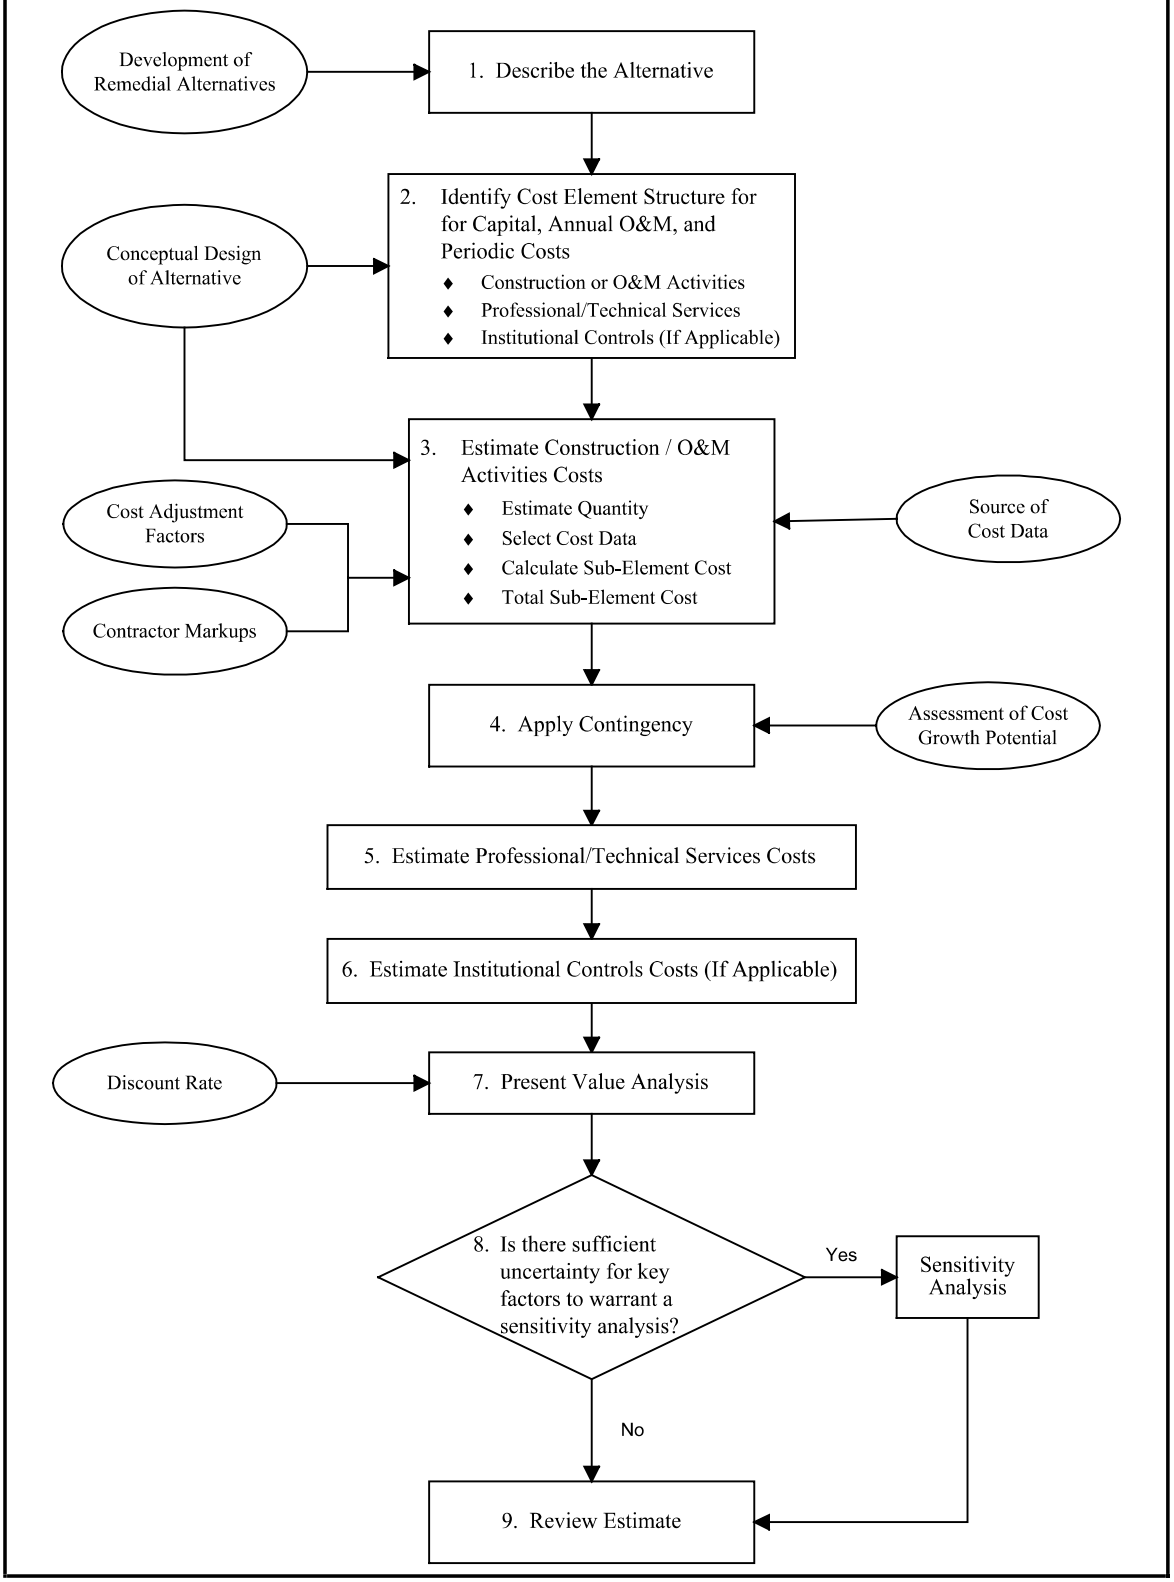
These steps are presented as a flowchart in Exhibit 5-1 and described in further detail in the following chapter sections.

Types of Cost Estimating Methods

Two main types of methods used to estimate the cost of remedial alternatives are the detailed and parametric approach.

The detailed approach estimates costs on an item-by-item basis. Detailed methods typically rely on quantity take-offs and compiled sources of unit cost data for each item, taken from either a built-in database (if part of a software package, for example) or other sources (e.g., cost estimating references). This method, also known as "bottom up" estimating, is used when design information is available.

The parametric approach relies on relationships between cost and design parameters. These relationships are usually "statistically-based" or "model-based." Statistically-based approaches rely on "scaled-up" or "scaled-down" versions of projects where historical cost data is available. Model-based approaches utilize a generic design that is linked to a cost database and adjusted by the user for site-specific information. This method, also known as "top down" estimating, is used when design information is not available.



Some resources that utilize these methods can be found in Appendix A.

5.1 Describe the Alternative

As the first step in development of the cost estimate, the remedial alternative should be described in general terms. An example of a descriptive narrative for an alternative that utilizes the technologies of air sparging, soil vapor extraction, and passive treatment wall is as follows:

> "Alternative 3 consists of air sparging and soil vapor extraction to treat soil and groundwater contaminated with volatile organic compounds in the source area. Also includes a passive treatment wall along the leading edge of the plume to treat groundwater migrating off-site. Capital costs occur in Year 0. Annual O&M costs occur in Years 1-15. Periodic costs occur in Years 5, 10, and 15."

Exhibit 5-1
Steps to Develop a Basic Cost Estimate for a Remedial Alternative

In addition to the above, the name and location of the site, phase of project (e.g., FS), and date of estimate preparation should be noted. The remedial alternative, as part of the alternative development process, will typically be described in greater detail in the body of the FS report. This detail should state remedial action objectives, including cleanup goals. At the time the estimate is developed, a conceptual design of the remedial alternative should have been completed or should be in progress. The identification of the cost element structure (Step 2), as well as estimation of quantities (included in Step 3), is directly related to the conceptual design of the alternative (i.e., level of project definition). The narrative, as shown in the above example, is not meant to describe every detail of the alternative, but provide a point of reference for developing the cost estimate.

5.2 Identify Cost Element Structure

Following the description, the second step is to identify the cost element structure for the alternative. A separate structure should be identified for capital, annual O&M, and periodic costs. This can be done with the help of checklists presented in Chapter 3 or standard work breakdown structures. For capital, annual O&M, and periodic cost element structures, the following steps apply:

1. Identify construction or O&M activities cost elements.
2. Identify professional/technical services cost elements.
3. Identify institutional controls cost elements, if applicable.

Construction or O&M activities include labor, equipment, and material costs for the contractor constructing the remedial action or for the contractor operating, maintaining, and/or monitoring the remedial action. Sub-elements should be identified, as required, to adequately describe each construction or O&M activity.

Professional/technical services support construction or operation and maintenance of the remedial action. Sub-elements for professional/technical services costs may be identified, as appropriate. Institutional controls can be a one-time (e.g., capital) or recurring cost (e.g., annual O&M, periodic). Sub-elements should generally be identified for institutional controls, as appropriate.

An example cost element structure for a remedial alternative that utilizes the technologies of air sparging (AS), soil vapor extraction (SVE), and a passive treatment wall is shown in Exhibit 5-2.

Exhibit 5-2
Example Cost Element Structure

Capital Costs

- Mobilization / Demobilization
  - Construction Equipment and Facilities
  - Submittals/Implementation Plans
  - Temporary Facilities & Utilities
  - Post-Construction Submittals
- Monitoring, Sampling, Testing, and Analysis
  - SVE Monitoring Wells
  - Treatment Wall Monitoring Wells
- Site Work
  - Clearing and Grubbing
  - Seeding/Mulch/Fertilizer
- Air Sparging / Soil Vapor Extraction
  - Mobilize SVE System
  - AS Injection Wells
  - AS Blower
  - AS Piping
  - SVE System
  - SVE Extraction Wells
  - SVE Piping
  - Electrical Hookup
  - Startup and Testing
- Passive Treatment Wall
  - Construct Slurry Trench
  - Install Reactive Media
- Off-Site Treatment/Disposal
  - Off-Site Transport of Soil Cuttings
  - Off-Site Disposal of Soil Cuttings
  - Wastewater Discharge/Testing
- Project Management
- Remedial Design
- Construction Management
- Institutional Controls
  - Institutional Controls Plan
  - Groundwater Use Restriction
  - Site Information Database

Annual O&M Costs

- Performance Monitoring
  - SVE Vapor Monitoring
  - SVE Emissions Monitoring
  - Treatment Wall - Groundwater Sampling
  - Treatment Wall - Groundwater Analysis
- Site Monitoring
  - Groundwater Sampling
  - Groundwater Laboratory Analysis
- Air Sparging / Soil Vapor Extraction
  - Operations Labor
  - Maintenance Labor
  - Equipment Repair
  - Utilities
- Off-Site Treatment/Disposal
  - Wastewater Discharge/Testing
- Project Management
- Technical Support
- Institutional Controls
  - Site Information Database

Periodic Costs

- Five Year Reviews
- Demobilization of AS/SVE System
- Well Abandonment
- Remedial Action Report
- Update Institutional Controls Plan

5.3 Estimate Construction/O&M Activities Costs

Following the description and identification of cost element structure, the cost of each construction or O&M activity is estimated. If the cost element is broken down into sub-elements, the cost of each sub-element should be estimated and then added for a cost element subtotal. The steps in this process include:

1. Estimate quantity.
2. Select cost data.
3. Calculate sub-element cost, including adjustments and application of markups.
4. Total sub-element costs.

These steps are described in more detail below.

Estimate Quantity

The estimation of quantities is directly related to the quality and quantity of site characterization data. For example, the estimated quantity of soil or groundwater contaminated above a cleanup goal or action level (i.e., quantity to be "cleaned up") is dependent upon data collected during the RI to determine nature and extent of contamination. Likewise, the estimated soil vapor extraction rate or groundwater pumping rate is dependent on the methods used to estimate air permeability or hydraulic conductivity (e.g., estimated values based on soil type, field pumping tests), as well as the operating capacity of the equipment (e.g., sizing of pumps, blowers, etc.). Other factors can affect the quantity estimate, such as the expected "swell" or "fluff" in volume of excavated material for an ex situ soil cleanup and the anticipated number of aquifer volumes to remove for an ex situ groundwater cleanup.

Quantity calculations used to support a cost estimate should be adequately documented. Supporting information can include boring logs, chemical analysis results, and scaled drawings to show lateral and vertical extent of contamination and to estimate physical characteristics such as porosity and dry unit weight which affect the quantity estimate. Assumptions used to estimate quantities should be clearly presented.

Using the example cost element structure shown in Exhibit 5-2, example quantities for capital costs would be the number of SVE monitoring wells, acres of clearing and grubbing, lineal feet of SVE piping, cubic yards of reactive media, etc. Example quantities for annual O&M costs would be the number of groundwater sampling events for site monitoring, number of months of operations labor for the AS/SVE system, etc.

Select Cost Data

Cost data can be selected from a variety of sources, including:

- Cost estimating guides/references
- Vendor or contractor quotes

- Experience with similar projects
- Cost estimating software/databases

Cost estimating guides or references (e.g., unit price books) can provide costs for a wide variety of construction activities, including those related to remedial actions. Some guides are specifically tailored to estimate costs for environmental remediation projects. Cost data in these references are sometimes broken down into labor, equipment, and material categories, and may or may not include contractor markups. Generally, each cost is associated with a specific labor and equipment crew and production rate. Costs are typically provided on a national average basis for the year of publication of the reference. Some of these guides or references are listed in Appendix A.

Quotes from vendors or construction contractors can provide costs that are more site-specific in nature than costs taken from standard guides and references. These quotes usually include contractor markups and are usually provided as a total cost rather than categorized as labor, equipment, or materials. If possible, more than one vendor quote should be obtained. Quotes from multiple sources can be averaged, or the highest quote can be used in the cost estimate if the collected quotes seem to be at the low end of the industry range. Vendors or contractors can also be an important source of design-related information, including operating capacity, production rates, operating life, and maintenance schedules that may have implications for O&M costs.

Experience with similar projects, including both estimates and actual costs, can also be used as a source of cost data. Engineering judgement should be exercised where cost data taken from another project needs to be adjusted to take into account site- or technology-specific parameters. Sources of actual cost data from government remediation projects are maintained by various Federal agencies. These sources include the Historical Cost Analysis System (HCAS) (*http://www.frtr.gov/cost/ec2/index.html*) and Federal Remediation Technologies Roundtable (FRTR) cost and performance reports (*http://www.frtr.gov/cost/*). HCAS and the FRTR reports are two initiatives that are currently being used to collect and record treatment technology costs in a standardized format. Some of these sources of historical cost data are listed in Appendix A.

Cost estimating software and databases can also be used as sources of cost data. The majority of available software tools are designed to estimate the cost for all or selected cost elements of an alternative. Government-sponsored software tools include Micro Computer Aided Cost Engineering System (MCACES), which is used by the U.S. Army Corps of Engineers and is linked to the Unit Price Book (UPB) database (*http://www.hnd.usace.army.mil/traces/*), and the Remedial Action Cost Engineering and Requirements (RACER), which is sponsored by the U.S. Air Force (*http://www.talpart.com/products/racer/index.html*). Some of these software or databases, both private and publicly sponsored, are listed in Appendix A.

Calculate Sub-Element Cost

Calculating the cost of each sub-element consists of calculating a unit cost from a source of cost data, including adjustments for site- or project-specific factors, and multiplying by the estimated quantity. Adjustments may include the following:

- Apply productivity factors per health and safety level of protection
- Escalate costs to base year of estimate
- Apply area cost factors
- Add contractor markups

As the level of health and safety protection (e.g., personal protective equipment, monitoring requirements) is increased, productivity is decreased and costs are increased. For applicable cost elements, factors that reflect decreased productivity due to required health and safety levels of protection should be applied to labor and equipment costs. More information on productivity factors and how to apply them is provided in Appendix B.

Health and Safety Impacts

Factors that may affect both capital and O&M cost elements due to health and safety precautions include:

- Decontamination facilities and operations
- Protective equipment cost and disposal
- Additional labor for health and safety personnel
- Rest periods required to prevent heat stress or cold weather impacts
- Time to suit-up, decontaminate, and change air tanks
- Personnel training
- Health and safety briefings and meetings

Some of these costs can be accounted for in overhead or specific cost elements. How to account for the impacts of health and safety level of protection on labor and equipment productivity is described in Appendix B.

Unit costs that are obtained from sources that are one year old or more need to be updated or escalated to the base year, which is usually the current year. This can be done using escalation factors as described in Appendix B.

Area cost factors should be applied to unit costs from sources based on a national average (e.g., standard cost guides) or from other geographic locations (e.g., similar projects). Area cost factors are further described in Appendix B.

Contractor markups, or overhead and profit, which may vary between sub-elements, should be added. Markups include overhead and profit for the prime contractor and any subcontractors. Markups should generally be applied to individual cost elements or sub-elements, but, alternatively, can be applied to the total of those elements, if the source of cost data for each is the same. Markups should not be duplicated or applied to elements that have already been "marked up."

The source of cost data can dictate how, or if, markups should be applied. For example, a vendor or contractor quote may include overhead and profit (i.e., "burdened"), whereas a unit price taken from a standard cost estimating guide may not (i.e., "non-burdened"). Typically, costs taken from pricing guides need to have overhead and profit added.

Overhead includes two main types: (1) job or field office overhead, also known as general conditions, and (2) home office overhead, also known as general and administrative (G&A) costs. Field office overhead can include costs for field supervision and office personnel, temporary facilities and utilities, telephone and communications, permits and licenses, travel and per diem, personal protective equipment, quality control, insurance, bond, and taxes. Home office overhead is the contractor's overall cost of doing business, as shared by the project. Profit is the return on the contractor's investment in the project.

- ***Field office overhead can range from about 5 to 25 percent of total project costs that range from greater than $500,000 to less than $50,000, respectively. Home office overhead is usually about 5 percent of total project cost.***

- ***Profit typically ranges from 8 to 10 percent of total project cost.***

An example of how a unit cost for a sub-element might be calculated is shown in Exhibit 5-3 for construction cost of a soil vapor extraction well.

Exhibit 5-3
Example Calculation of Sub-Element Unit Cost

Costs per extraction well:

DESCRIPTION	QTY	UNIT	LABOR	EQUIP	MTRL	UNIT TOTAL	TOTAL
Mob/demob	1	LS	-	-	-	100	100
Setup & Decon	1	HR	-	-	-	125	125
Drill & Install	15	FT	-	-	-	55	825
Wellhead Completion	1	LS	-	-	-	950	950
IDW Handling	1	HR	-	-	-	175	175
Drilling Oversight	7	HR	110	-	-	110	770
SUBTOTAL							2,945
Prime Contractor Overhead						15%	442
SUBTOTAL							3,387
Prime Contractor Profit						10%	339
TOTAL UNIT COST							$3,725

In this example, costs are based on a quote from a local drilling subcontractor, itemized by activity. The assumed health and safety level of protection is built into the quote; therefore, no outside adjustment is made for health and safety productivity. Likewise, no costs are escalated, since the base year is the current year, and no area cost factor is applied, since the quote is local. Subcontractor overhead and profit are included in the quote. Prime contractor overhead and profit are added. Unit prices taken from standard cost estimating guides typically are broken down into labor, equipment, and materials categories. However, since these were not provided in the quote, these are not shown except for oversight, which is based on typical labor rates in the area for a geologist and technician.

Using the above example, if eight soil vapor extraction wells are to be installed, then the total cost of this sub-element would be 8 x $3,725 = $29,800.

Total Sub-Element Costs

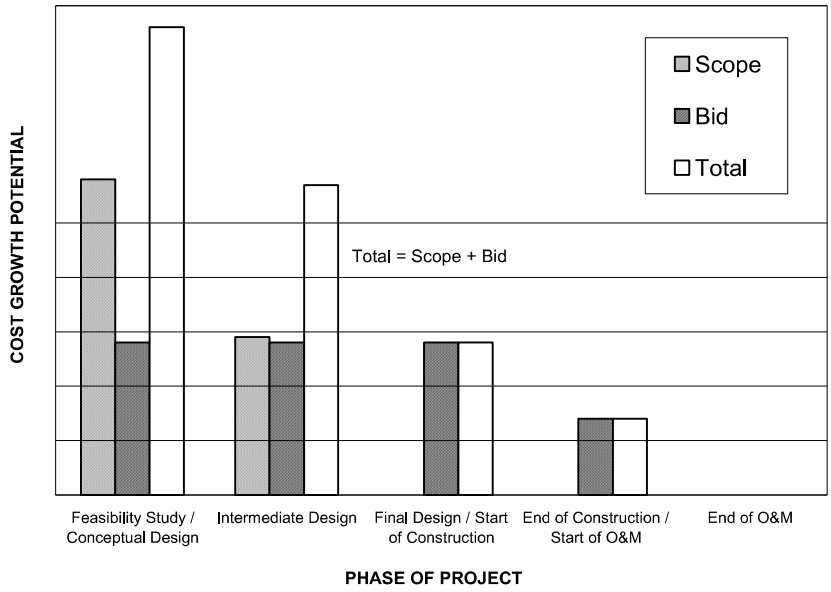
After the cost for each sub-element has been calculated, then the cost of the associated cost element can be calculated by totaling the sub-element costs. An example is shown in Exhibit 5-4 for construction cost of an air sparging / soil vapor extraction system.

Exhibit 5-4
Example Estimation of Cost Element

Air Sparging / Soil Vapor Extraction				
Mobilize SVE System	1	EA	$1,534	$1,534
Impermeable Surface Cover	105,000	SF	$0.84	$88,200
SVE Extraction Wells	8	EA	$3,725	$29,803
AS Injection Wells	2	EA	$4,645	$9,290
SVE System	1	EA	$93,510	$93,510
AS Blower	1	EA	$5,712	$5,712
SVE Piping	400	LF	$8.66	$3,464
AS Piping	100	LF	$5.03	$503
Electrical Hookup	1	LS	$9,898	$9,898
Startup and Testing	1	LS	$10,936	$10,936
SUBTOTAL				$252,851

This example includes the sub-element "SVE Extraction Well" from Exhibit 5-3.

5.4 Apply Contingency



Contingency is factored into a cost estimate to cover unknowns, unforeseen circumstances, or unanticipated conditions that are not possible to evaluate from the data on hand at the time the estimate is prepared. It is used to reduce the risk of possible cost overruns.

For the purposes of the FS, contingency is typically applied as a percentage of the total cost of construction or O&M activities costs, rather than applied to individual cost elements. The contingency percentage is based on either a qualitative or quantitative assessment of "cost growth," or "cost risk," potential.[1] Detailed quantitative methods used to evaluate cost growth potential include element by element risk scoring and weighting techniques and risk analysis software such as CostRisk, which is currently under development for use by USACE. A more common approach for the FS, however, is to assign a contingency percentage based on engineering judgement.

The two main types of contingency are scope and bid. Scope contingency covers unknown costs due to scope changes that may occur during design. Bid contingency covers unknown costs associated with constructing or implementing a given project scope. The relationship of scope, bid, and total contingency as a project moves through its various phases is illustrated in Exhibit 5-5.

[1] Factors that affect the potential for cost growth in remediation projects include the project definition and the complexity of the media, waste, and technical aspects of the project.

Exhibit 5-5
Relationship of Scope, Bid, and Total Contingency

Scope Contingency

Scope contingency represents project risks associated with an incomplete design. This type of contingency represents costs, unforeseeable at the time of estimate preparation, which are likely to become known as the remedial design proceeds (Exhibit 5-5). For this reason, scope contingency is sometimes referred to as "design" contingency, which is the term commonly used by the USACE. In general, scope contingency should decrease as design progresses and should be 0% at the 100% design stage.

At the early stages of remedial design (e.g., FS which represents 0%-10% design completion), concepts are not typically developed enough to identify all project components or quantities. Contributing factors include limited experience with certain technologies, potential requirements due to regulatory or policy changes, and inaccuracies in defining quantities or characteristics. Scope contingency would be expected to be higher for newer or emerging remedial technologies than for more well-documented systems. For these reasons, scope contingency may vary between alternatives.

Scope contingency typically ranges from 10 to 25 percent. Higher values may be justified for alternatives with greater levels of cost growth potential.

Exhibit 5-6 shows example rule-of-thumb percentage ranges to use for scope contingency during the FS, based on type of remedial technology. A low percentage for scope contingency indicates an opinion that the project scope will undergo minimal change during

design. A high percentage indicates an opinion that the project scope may change considerably between the FS and final design.

Exhibit 5-6
Example FS-Level Scope Contingency Percentages

Remedial Technology	Scope Contingency (%)
Soil Excavation	15-55
Groundwater Treatment (Multiple)	15-35
On-Site Incineration	15-35
Extraction Wells	10-30
Vertical Barriers	10-30
Synthetic Cap	10-20
Sludge Stabilization	10-20
Off-Site Disposal	5-15
Off-Site Incineration	5-15
Drum Processing	5-15
Bulk Liquid Processing	5-15
Groundwater Treatment (Single)	5-10
Clay Cap	5-10
Surface Grading/Diking	5-10
Revegetation	5-10

While not accounting for every type of remedial technology, this exhibit provides a range of values to consider for scope contingency. Engineering judgement should be used whenever selecting a scope contingency percentage and the value used should be clearly identified in the cost estimate. The values in Exhibit 5-6 may be weighted by cost element, either qualitatively or quantitatively, to derive a single value to apply to the total of construction or O&M activities costs.

Bid Contingency

Bid contingency represents costs, unforeseeable at the time of estimate preparation, which are likely to become known as the remedial action construction or O&M proceeds (Exhibit 5-5). For this reason, bid contingency is sometimes referred to as "construction" contingency, which is the term commonly used by the USACE.

Bid contingency accounts for changes that occur after the construction contract is awarded. This contingency represents a reserve for quantity overruns, modifications, change orders, and/or claims during construction. Considerations include the technological, geotechnical, and other unknowns applicable to the construction phase. Examples include changes due to adverse weather, material or supply shortages, or new regulations.

- ***Bid contingency typically ranges from 10 to 20 percent.***

Bid and scope contingency may be added together and applied to the total of construction or O&M activities costs as shown in the example in Exhibit 5-7 for capital costs.

Exhibit 5-7
Example Contingency Application

Capital Costs:	
Mobilization / Demobilization	$106,723
Monitoring, Sampling, Testing, and Analysis	$60,838
Site Work	$12,940
Air Sparging / Soil Vapor Extraction	$252,851
Passive Treatment Wall	$2,028,564
Off-Site Treatment / Disposal	$1,550
SUBTOTAL	$2,463,465
Contingency (10% scope + 15% bid)	615,866

In general, for a cost estimate developed during the FS, the same level of risk associated with remedial design for capital costs can be carried over to annual O&M costs. In addition, the relative number of unknowns associated with operating and maintaining a remedial action would be expected to be at least the same or greater than those associated with construction.

The total contingency value (bid + scope) that is applied to annual O&M costs is typically equal to or greater than the contingency applied to capital costs.

Using the example in Exhibit 5-6, the total contingency to apply to the total of "O&M activities" costs might be 30 percent (10% scope + 20% bid), or slightly greater than that for capital "construction activities" costs.

5.5 Estimate Professional/Technical Services Costs

Professional/technical services cost elements can be broken down into sub-elements and estimated in similar fashion to construction or O&M activities costs (Section 5.3). However, these costs are most often estimated by applying a percentage to the total of construction or O&M activities costs plus contingency. The total capital, annual O&M, or periodic cost, therefore, is the total of construction or O&M activities costs, contingency, and professional/technical services. Professional/technical services cost elements include:

- Project Management
- Remedial Design
- Construction Management
- Technical Support

For professional/technical services capital costs, Exhibit 5-8 shows rule-of-thumb percentages that can be used for project management, remedial design, and construction management as a percentage of total construction cost. The percentages shown apply to the average remediation project and are provided as a guide. These values may be adjusted up

for more complex projects or down for less complex projects, based on engineering judgement, which might consider actual cost data from similar projects.

Exhibit 5-8
Example Percentages for Professional/Technical Services Capital Costs

Capital Cost Element	< $100K (%)	$100K-$500K (%)	$500K-$2M (%)	$2M-$10M (%)	> $10M (%)
Project Management	10	8	6	5	5
Remedial Design	20	15	12	8	6
Construction Management	15	10	8	6	6

Professional/technical services costs are further described below.

Project Management

Project management, which can apply to either capital or O&M cost, includes services that are not specific to remedial design, construction management, or technical support of O&M activities. Project management includes planning and reporting, community relations support during construction or O&M, bid or contract administration, permitting (not already provided by the construction or O&M contractor), and legal services outside of institutional controls (e.g., licensing).

- ***For capital costs, project management can be estimated using Exhibit 5-8. For O&M costs, project management generally ranges from 5 to 10 percent of total annual O&M cost.***

Remedial Design

Remedial design applies to capital cost and includes services to design the remedial action. Activities that are part of remedial design include pre-design collection and analysis of field data, engineering survey for design, treatability study (e.g., pilot-scale), and the various design components such as design analysis, plans, specifications, cost estimate, and schedule at the preliminary, intermediate, and final design phases.

- ***The percentage of total capital cost for remedial design can be estimated using Exhibit 5-8.***

Construction Management

Construction management applies to capital cost and includes services to manage construction or installation of the remedial action, except any similar services provided as part of regular construction activities. Activities include review of submittals, design modifications, construction observation or oversight, engineering survey for construction, preparation of O&M manual, documentation of quality control/quality assurance, and record drawings.

- ***The percentage of total capital cost for construction management can be estimated using Exhibit 5-8.***

Technical Support

Technical support during O&M includes services to monitor, evaluate, and report progress of remedial action (i.e., all O&M professional/technical services not provided under project management). This includes oversight of O&M activities, update of O&M manual, and progress reporting.

- ***O&M technical support generally ranges from 10 to 20 percent of total annual O&M cost.***

An example of how professional/technical services cost elements would be estimated using percentages and added to the total of construction cost elements plus contingency is shown in Exhibit 5-9 for capital costs.

Exhibit 5-9
Example Estimation of Professional/Technical Services Costs

CONSTRUCTION SUBTOTAL	$2,463,465
Contingency (10% scope + 15% bid)	615,866
SUBTOTAL	$3,079,331
Project Management (5%)	153,967
Remedial Design (8%)	246,346
Construction Management (6%)	184,760
TOTAL	$3,664,404

5.6 Institutional Controls

Institutional controls, which can have one-time or recurring costs (capital, annual O&M, or periodic), are non-engineering or legal/administrative measures to reduce or minimize the potential for exposure to site contamination or hazards by limiting or restricting site access.

Examples include institutional controls plan, restrictive covenants, property easements, zoning, deed notices, advisories, groundwater use restrictions, and site information database. An institutional controls plan would describe the controls for a site and how to implement them. A site information database would provide a system for managing data necessary to characterize the current nature and extent of contamination.

Institutional controls are project-specific costs that can be an important component of a remedial alternative and, as such, should generally be estimated separately from other costs, usually on a sub-element basis. Institutional controls may need to be updated or maintained, either annually or periodically. Contingency is generally not applied to institutional control

cost elements. An example of how institutional controls cost elements would be estimated as for capital costs is shown in Exhibit 5-10.

Exhibit 5-10
Example Estimation of Institutional Controls Costs

Institutional Controls				
Institutional Controls Plan	1	EA	$5,000	$5,000
Groundwater Use Restriction	1	LS	$3,200	$3,200
Site Information Database	1	LS	$4,800	$4,800
SUBTOTAL				$13,000

5.7 Present Value Analysis

To allow for comparison of different alternatives on the basis of a single cost figure, the present value of capital, annual O&M, and periodic costs should be analyzed according to the procedures in Chapter 4. Discount factors, either single-year or multi-year, should be carefully selected depending on the period of analysis to which they are applied. An example present value analysis of the different types of cost for a remedial alternative is shown in Exhibit 5-11.

Exhibit 5-11
Example Present Value Analysis

COST TYPE	YEAR	TOTAL COST	TOTAL COST PER YEAR	DISCOUNT FACTOR (7%)	PRESENT VALUE
Capital Cost	0	$3,677,404	$3,677,404	1.000	$3,677,404
Annual O&M Cost	1-15	$4,590,763	$306,051	9.108	$2,787,511
Periodic Cost	5	$14,800	$14,800	0.713	$10,552
Periodic Cost	10	$14,800	$14,800	0.508	$7,518
Periodic Cost	15	$48,458	$48,458	0.362	$17,542
		$8,346,000			$6,501,000

5.8 Sensitivity Analysis

Sensitivity analysis is a type of uncertainty analysis that measures the project impact of changing one or more input values. In the development of a remedial alternative cost estimate, a sensitivity analysis should be considered for those factors that have a relatively-high degree of uncertainty and that, with only a small change in their value, could significantly affect the overall cost of the alternative. This type of analysis is considered separate from a "cost growth" or "cost risk" analysis used to determine the amount of

contingency to apply to the cost estimate (Section 5.4). However, a sensitivity analysis could be used to support a contingency analysis (e.g., to help select site-specific contingency factors).

Factors to consider in a cost sensitivity analysis for a remedial alternative include:

- Nature and Extent of Contamination – Estimated volumes of contaminated media or material and degree of contamination (i.e., concentrations) are dependent on assumptions about site conditions.
- Remedy Failure / Effective Life of Technology - The potential failure of a remedy or components thereof would require substantial additional costs for replacement of the remedy or its components. Particularly relevant for technologies or processes that are unproven and lack sufficient performance history.
- Project Duration – The time required for a remedial action, or components thereof, to achieve remedial action objectives can be a major factor, particularly for those actions requiring many years of O&M.
- Discount Rate – Although a rate of 7% should normally be used to compare alternatives, a range of values both below and above 7% can be used to investigate uncertainty concerning future economic conditions.

A sensitivity analysis might vary the values for these factors (e.g., low, medium, high), while keeping the values for other factors the same, and noting the impact on the total estimated cost. Advantages of a sensitivity analysis include:

- Helps identify critical factors where additional data collection resources may need to be spent during subsequent phases of remedial design.
- Provides potential answers to "what if" scenarios.
- Does not require the use of probabilities as do other methods, such as Monte Carlo analysis.

The results of a sensitivity analysis should be reported in terms of total present value for each scenario. The baseline, or original estimate, should be included for comparison. An example of how the results of a sensitivity analysis might be presented is shown in Exhibit 5-12. Scenario 1 is the baseline. In Scenario 2, the project duration is extended by ten years. In Scenario 3, a major capital expenditure is required in Year 8 (e.g., replacement of reactive iron in a treatment wall).

Exhibit 5-12
Example Sensitivity Analysis

YEAR	PRESENT VALUE COST 1	2	3
0	$3,677,404	$3,677,404	$3,677,404
1	$286,029	$286,029	$286,029
2	$267,317	$267,317	$267,317
3	$249,829	$249,829	$249,829
4	$233,485	$233,485	$233,485
5	$228,762	$228,762	$228,762
6	$203,935	$203,935	$203,935
7	$190,593	$190,593	$190,593
8	$178,124	$178,124	$1,358,767
9	$166,471	$166,471	$166,471
10	$163,104	$163,104	$163,104
11	$145,403	$145,403	$145,403
12	$135,890	$135,890	$135,890
13	$127,000	$127,000	$127,000
14	$118,692	$118,692	$118,692
15	$128,490	$116,291	$128,490
16		$103,670	
17		$96,888	
18		$90,549	
19		$84,626	
20		$82,914	
21		$73,915	
22		$69,080	
23		$64,560	
24		$60,337	
25		$65,318	
TOTAL	**$6,501,000**	**$7,280,000**	**$7,681,000**

1. Baseline - original estimate.
2. Project duration is increased by 10 years.
3. Reactive iron for treatment wall is replaced in Year 8.

5.9 Review Estimate

The last step in the process is to review the estimate for completeness. Exhibit 5-13 is a checklist to help review the cost estimate for a remedial alternative.

Exhibit 5-13
Key Questions to Ask when Reviewing a Remedial Alternative Cost Estimate

1. Has a description of the alternative been provided?

   - If so, are key processes or technologies identified per the development process and conceptual design of alternative?
   - Have the site, location, and project phase been noted?

2. Have the capital, annual O&M, and periodic cost element structures been fully developed?

   - Have all applicable construction or O&M activities costs elements been identified?
   - Have all applicable professional/technical services cost elements been identified?
   - Have all applicable institutional controls cost elements been identified?

3. Have quantities for construction and O&M activities cost elements been estimated with sufficient backup?

   - Have calculation sheets, drawings, vendor information, or similar supporting data been included?
   - Have assumptions used to estimate quantities been clearly identified?

4. Have unit costs for construction and O&M activities cost elements been estimated with sufficient backup?

   - Is the source of cost data identified? Is the source appropriate?
   - Are sub-elements described in sufficient detail with assumptions clearly identified?
   - Have all assumptions been taken into account?
   - Have labor, equipment, and materials been included?
   - Has crew production rate or cost been adjusted to account for inefficiency associated with health and safety level of protection?
   - If a cost has been taken from another estimate or a published cost reference, has it been adjusted it to account for different location (area cost factor) and for different time (escalation to base year)?
   - Has subcontractor, if applicable, and prime contractor markups (i.e., overhead, profit) been added?
   - Are the percentages used for overhead and profit appropriate?
   - Have any markups been duplicated?
   - Are quotations from suppliers and subcontractors documented in the backup?

5. Has contingency been applied to the total of construction or O&M activities costs?

   - Have both scope and bid contingency been considered?
   - Are the values used for percentages appropriate, considering the technologies utilized by the alternative?

Exhibit 5-13 (cont.)
Key Questions to Ask when Reviewing a Remedial Alternative Cost Estimate

6. Have the applicable professional/technical services costs been added?

   - If estimated on a percentage basis, are the values used appropriate, considering the total project cost and complexity?

7. If applicable, have the costs associated with implementing and maintaining institutional controls been estimated?

8. Were guidelines followed for the present value analysis?

   - Is the period of present value analysis different than the anticipated project duration (i.e., time required for design, construction, O&M, and closeout)? If so, is explanation provided?
   - Are all capital, annual O&M, and periodic costs included in the present value analysis?
   - Is the discount rate used consistent with USEPA policy (e.g., 7%)? If not, is explanation provided?
   - Is the same discount rate used across all of the alternatives analyzed?
   - If discount factors were used, have the appropriate single-year or multi-year factors been applied, considering the period of analysis for each type of cost (i.e., capital, annual O&M, periodic)?

9. Is there sufficient uncertainty for key factors to warrant a sensitivity analysis? If a sensitivity analysis was done, are results presented clearly in terms of total present value of the alternative?

Chapter Six

How to Document the Cost Estimate

Cost estimates of remedial alternatives developed during the FS should be documented within the FS report such that costs and underlying assumptions are clearly presented and understood. Documentation for the FS should be structured using the following three components:

- Detailed cost backup
- Cost summary of individual remedial alternatives
- Comparative cost summary of all remedial alternatives

These components are described further in the following three chapter sections. The fourth section provides information on post-RI/FS documentation of the cost estimate of the proposed or selected remedy.

6.1 Detailed Cost Backup

Detailed cost backup for remedial alternative cost estimates should be provided in an appendix to the FS report. This material can include cost calculation sheets, quantity calculation sheets, records of communication for vendor quotes, and conceptual design calculations. If cost estimating software is used to estimate all or part of the costs for remedial alternatives, input/output from these software applications should be provided as part of the detailed backup.

For each cost element or sub-element, a standard worksheet can be used to document the calculation of the total unit cost as shown in Exhibit 6-1 for the example of an SVE extraction well. This type of cost worksheet, together with quantity calculation sheets and other supporting information, can be used to trace each cost shown in the cost summary of an alternative to its underlying assumptions.

6.2 Individual Cost Summary

The cost estimate of each remedial alternative should be presented in a one- to two-page cost summary table such as the example shown in Exhibit 6-2. The individual cost summary should present all capital costs, annual O&M costs, any periodic costs, and present value analysis for the remedial alternative. The cost summary should be an activity-based format that identifies all cost elements and sub-elements of the alternative. Individual cost summaries should be provided within the individual analysis section of the FS report or within a cost estimate appendix to the FS report.

6.3 Comparative Cost Summary

The total estimated cost for all remedial alternatives should be presented within the comparative analysis section of the FS report in a summary table such as the example shown in Exhibit 6-3. Alternatively, costs for remedial alternatives can be compared as part of the

detailed analysis table, typically provided in FS reports to compare the alternatives against each of the nine NCP criteria. The total cost presented for each alternative should include total capital cost, annual O&M cost, total periodic cost (if any), and total present value. The project duration in years should be noted as this impacts the present value analysis. It should also be noted when the period of present value analysis differs from the project duration. If there are different annual O&M costs for different periods of time, this may need to be broken out in the comparative cost summary.

6.4 Cost Estimate of Proposed or Selected Remedy

Following the RI/FS, as part of the remedy selection process, the cost estimate of the selected remedy is summarized in the record of decision (ROD). In addition, cost information for proposed remedies that meet certain cost-based criteria is submitted to the National Remedy Review Board (NRRB) for review. The following paragraphs, primarily intended for the audience of remedial project managers and program managers, provide more detail on these two topics.

Record of Decision

The same type of one- to two-page format shown in Exhibit 6-2 for remedial alternative cost estimates developed during the FS can be used to present the cost summary of the selected remedy in the ROD. During remedy selection, the preferred alternative presented in the proposed plan can undergo changes as a result of public comment or new information such as additional site characterization data. Any changes to the selected remedy should be reflected in the cost summary presented in the ROD. In addition, if the remedy selection process has spanned a considerable amount of time (e.g., more than 1 year), the estimated costs should be escalated to a new base year. Standard cost estimate disclaimer language should be added to acknowledge the uncertainty associated with cost estimates (see highlight box to right). For more information on the presentation of estimated remedy costs in the ROD, see *A Guide to Preparing Superfund Proposed Plans, Records of Decision, and Other Remedy Selection Documents* (USEPA 1999).

Standard Cost Estimate Disclaimer Language

"The information in this cost estimate summary table is based on the best available information regarding the anticipated scope of the remedial alternative. Changes in the cost elements are likely to occur as a result of new information and data collected during the engineering design of the remedial alternative. Major changes may be documented in the form of a memorandum in the administrative record file, an explanation of significant differences, or a ROD amendment. This is an order-of-magnitude engineering cost estimate that is expected to be within –30 to +50 percent of the actual project cost."

Source: *A Guide to Preparing Superfund Proposed Plans, Records of Decision, and Other Remedy Selection Decision Documents* (USEPA 1999)

National Remedy Review Board

The NRRB is a peer review group comprised of USEPA managers and senior technical policy experts that reviews proposed Superfund cleanup decisions meeting cost-based review criteria to assure that they are consistent with Superfund law, regulations, and guidance. In general, the NRRB reviews those cleanup decisions that exceed specific cost criteria. For

more information on the NRRB, its procedures, and cost criteria that trigger reviews, visit *http://www.epa.gov/superfund/programs/nrrb/*.

The following provides guidance for submitting remedy cost estimate information to the NRRB that should accompany briefing materials to allow the NRRB to more accurately assess the cost-effectiveness of the proposed remedy:

1. The summary materials should contain sufficient information to provide an estimate of total resource costs over time (i.e., life cycle costs). Pursuant to the NCP, this estimate should include the capital costs, annual operations and maintenance costs, and net present value of capital and O&M costs. Cost information should be provided for the preferred alternative, as well as each alternative evaluated in the detailed analysis of the FS (or which will be listed in the proposed plan).

2. Cost estimate summaries should address the following:

    a. The key cost components/elements for both RA and O&M activities;

    b. The major sources of uncertainty in the cost estimate;

    c. The discount rate used;

    d. The time expected to achieve remedial action objectives and remediation goals;

    e. Periodic capital and/or O&M costs anticipated in future years of the project (e.g., remedy replacement or rebuild);

    f. The methods and resources used for preparing the cost estimate (e.g., estimating guides, vendor quotes, computer cost models).

3. For "contingency remedy decisions," the total project costs for implementing the contingency should be provided in addition to the costs for the conditional action. This estimate should include treatability study costs, if applicable.

4. The assumptions used to develop the cost estimate should be consistent with the stated remedial action objectives and remediation goals (e.g., duration of the cost estimate should match time to achieve cleanup objectives).

This kind of information is generally considered useful in other management-level review settings as well.

Example Cost Worksheet

Alternative 3
Capital Cost Sub-Element
SVE EXTRACTION WELL

COST WORKSHEET

Site: Former Industrial Site
Location: Any City, Any State
Phase: Feasibility Study (-30% to +50%)
Base Year: 2000

Prepared By: MPM **Date:** 4/12/00
Checked By: JMR **Date:** 4/12/00

Work Statement:

Install SVE extraction well to total depth of 15 feet with 10-foot factory-slotted screen. Installation includes drilling with hollow-stem auger, continuous soil sampling, installation of 4-inch Schedule 40 PVC blank and screen with filter pack and grout seal, setup and decontamination, containerization of investigation-derived waste (IDW), and wellhead completion (concrete, flush-mount vault with lock, tee with valve and flexible coupling). Health and safety protection is Level D.

Cost Analysis:

Costs per extraction well:

DESCRIPTION	QTY	UNIT	LABOR	EQUIP	MTRL	UNIT TOTAL	TOTAL	
Mob/demob	1	LS	-	-	-	100	100	% of mob/demob for all wells
Setup & Decon	1	HR	-	-	-	125	125	
Drill & Install	15	FT	-	-	-	55	825	Includes well materials
Wellhead Completion	1	LS	-	-	-	950	950	Includes vault, tee with fittings
IDW Handling	1	HR	-	-	-	175	175	Includes drums
Drilling Oversight	7	HR	110	-	-	110	770	$65/hr geo + $45/hr technician
SUBTOTAL							2,945	
Prime Contractor Overhead						15.0%	442	
SUBTOTAL							3,387	
Prime Contractor Profit						10.0%	339	
TOTAL UNIT COST							$3,725	

Source of Cost Data:

3-20-00 quote from John Smith, ABC Drilling Services, tel. no. 999-999-9999. Rates for geologist and technician are based on typical labor rates for area.

Cost Adjustment Checklist:

	FACTOR:	NOTES:
☑	H&S Productivity (labor & equip only)	Quote is for Level D.
☑	Escalation to Base Year	Current year (2000) is base year.
☑	Area Cost Factor	Quote is from local vendor.
☑	Subcontractor Overhead and Profit	Included in quote.
☑	Prime Contractor Overhead and Profit	Includes 15% overhead and 10% profit.

Alternative 3
IN SITU TREATMENT

COST ESTIMATE SUMMARY

Site: Former Industrial Site
Location: Any City, Any State
Phase: Feasibility Study (-30% to +50%)
Base Year: 2000
Date: April 12, 2000

Description: Alternative 3 consists of air sparging in combination with soil vapor extraction to treat soil and groundwater in the source area. Also includes passive treatment wall along leading edge of plume to treat groundwater migrating off-site. Capital costs occur in Year 0. Annual O&M costs occur in Years 1-15. Periodic costs occur in Years 5, 10, and 15.

CAPITAL COSTS:

DESCRIPTION	QTY	UNIT	UNIT COST	TOTAL	NOTES
Mobilization / Demobilization					
Construction Equipment & Facilities	1	LS	$8,829	$8,829	Excavators, loaders, etc.
Submittals/ Implementation Plans	1	LS	$33,761	$33,761	QAPP, SSHP, etc.
Temporary Facilities & Utilities	1	LS	$49,664	$49,664	Fence, roads, signs, trailers, etc.
Post-Construction Submittals	1	LS	$14,469	$14,469	Post-const. reports
SUBTOTAL				$106,723	
Monitoring, Sampling, Testing, and Analysis					
Monitoring Wells - SVE	7	EA	$1,577	$11,040	Install to water table depth
Monitoring Wells - Trtmt. Wall - Shallow	5	EA	$2,965	$14,826	Shallow well at each of 5 clusters
Monitoring Wells - Trtmt. Wall - Deep	5	EA	$6,212	$31,061	Deep well at each of 5 clusters
Geotechnical Testing	17	EA	$230	$3,910	MW screen interval soil samples
SUBTOTAL				$60,838	
Site Work					
Clearing and Grubbing	5	AC	$1,161	$5,804	Work area
Seeding/Mulch/Fertilizer	5	AC	$1,427	$7,136	Revegetate work area

COST ESTIMATE SUMMARY

DESCRIPTION	QTY	UNIT	UNIT COST	TOTAL	NOTES
Performance Monitoring					
SVE Vapor Monitoring	96	EA	$308	$29,532	1 sample/month * 8 extraction wells
SVE Emissions Monitoring	12	EA	$308	$3,692	1 sample/month - SVE exhaust
Treatment Wall - Groundwater Sampling	4	QTR	$2,449	$9,795	Sample 10 wells/qtr
Treatment Wall - Groundwater Lab Analysis	4	QTR	$5,714	$22,856	Analysis for above
SUBTOTAL				$65,875	
Site Monitoring					
Groundwater Sampling	4	QTR	$1,820	$7,280	Sample 8 wells/qtr VOCs, WQ, metals
Groundwater Laboratory Analysis	4	QTR	$5,460	$21,839	Analysis for above
SUBTOTAL				$29,119	
Air Sparging / Soil Vapor Extraction					
Operations Labor	12	MO	$6,120	$73,440	136 manhours per month
Maintenance Labor	12	MO	$720	$8,640	16 manhours per month
Equipment Repair	1	LS	$500	$500	
Utilities	12	MO	$1,928	$23,134	Electricity + fuel
SUBTOTAL				$105,714	
Off-Site Treatment / Disposal					
Wastewater Discharge/Testing	1,600	GAL	$1.00	$1,600	City fee - purge & knockout water
SUBTOTAL				$202,308	
Contingency	30%			60,692	10% scope + 20% bid
SUBTOTAL				$263,001	
Project Management	5%			13,150	
Technical Support	10%			26,300	
Institutional Controls - Site Info Database	1	LS	$3,600	$3,600	Update and maintain database
TOTAL ANNUAL O&M COST				**$306,051**	

PERIODIC COSTS:

DESCRIPTION	YEAR	QTY	UNIT	UNIT COST	TOTAL	NOTES
Five Year Review Report	5	1	EA	$12,000	$12,000	1 report at end of Year 5
Update Institutional Controls Plan	5	1	EA	$2,800	$2,800	Update plan
SUBTOTAL					$14,800	
Five Year Review Report	10	1	EA	$12,000	$12,000	1 report at end of Year 10
Update Institutional Controls Plan	10	1	EA	$2,800	$2,800	Update plan
SUBTOTAL					$14,800	
Demobilize AS/SVE System	15	1	LS	$21,375	$21,375	Remove equipment and piping
Well Abandonment	15	27	EA	$350	$9,450	
Contingency (% of Sum)		25%			7,706	% of construction activities
Project Mgt. (% of Sum + Cont.)		5%			1,927	% of construction + contingency
Remedial Action Report	15	1	EA	$8,000	$8,000	
SUBTOTAL					$48,458	

PRESENT VALUE ANALYSIS:

COST TYPE	YEAR	TOTAL COST	TOTAL COST PER YEAR	DISCOUNT FACTOR (7%)	PRESENT VALUE	NOTES
Capital Cost	0	$3,677,404	$3,677,404	1.000	$3,677,404	
Annual O&M Cost	1-15	$4,590,763	$306,051	9.108	$2,787,511	
Periodic Cost	5	$14,800	$14,800	0.713	$10,552	5-year review, update i.c. plan
Periodic Cost	10	$14,800	$14,800	0.508	$7,518	5-year review, update i.c. plan
Periodic Cost	15	$48,458	$48,458	0.362	$17,542	Demob, abandon, RA report
		$8,346,000			$6,501,000	
TOTAL PRESENT VALUE OF ALTERNATIVE					**$6,501,000**	

Exhibit 6-3
Example Comparative Cost Summary

COMPARISON OF TOTAL COST OF REMEDIAL ALTERNATIVES

Site: Former Industrial Site
Location: Any City, Any State
Phase: Feasibility Study (-30% to +50%)
Base Year: 2000
Date: April 12, 2000

DESCRIPTION	Alternative 1 No Action	Alternative 2 Limited Action/ Natural Attenuation	Alternative 3 In Situ Treatment	Alternative 4 Ex Situ Treatment
Total Project Duration (Years)	0	30	15	15
Capital Cost	$0	$147,000	$3,677,000	$5,300,000
Annual O&M Cost	$0	$41,000	$306,000	$146,000
Total Periodic Cost	$0	$68,000	$72,000	$43,000
Total Present Value of Alternative	**$0**	**$690,000**	**$6,501,000**	**$6,649,000**

Appendix A
Internet Resources

This appendix provides a list of Internet resources that may be useful for the development of cost estimates of remedial alternatives during the FS. USEPA and USACE cannot endorse nor vouch for the content of any web site other than their own. All listed web site addresses were current at the time of appendix publication. In addition to description of content, the following icons are used next to resource listings to indicate what type of information each contains:

- Policy
- Technical
- $ Cost
- Software/Database
- Publication

These identifiers are used separately or together, depending on the resource. Exhibit A-1 presents Internet resources that are sponsored and maintained by government agencies and organizations. Exhibit A-2 presents private or non-government Internet resources. Major resource categories in Exhibit A-1 include:

- U.S. Environmental Protection Agency
- U.S. Army Corps of Engineers
- U.S. Department of Energy
- U.S. Department of Defense
- Other or Interagency

Major categories in Exhibit A-2 for non-government resources include:

- Private Firms/Companies
- Professional Societies/Organizations

Exhibit A-1

U.S. Environmental Protection Agency (USEPA)
http://www.epa.gov/

USEPA Superfund 🏛 📖 🛠 *http://www.epa.gov/superfund/*

The USEPA administers the Superfund program through the Office of Solid Waste and Emergency Response (OSWER) in cooperation with individual states and tribal governments. Superfund locates, investigates and cleans up the nation's hazardous waste sites. The web site provides information on the technical resources, initiatives, programs, and accomplishments of the Superfund program. Resources include:

- **Rules of Thumb for Superfund Remedy Selection** 📖
  http://www.epa.gov/superfund/resources/rules/index.htm

  This guidance document outlines key principles and procedures that should be consulted during the Superfund remedy selection process.

- **Role of Cost in the Superfund Remedy Selection Process** 📖
  http://www.epa.gov/superfund/resources/cost_dir/index.htm

  This document outlines the role of costs in the Superfund remedy selection process as established in the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA), the National Oil and Hazardous Substances Pollution Contingency Plan (NCP), and current EPA guidance documents.

- **A Guide to Preparing Superfund Proposed Plans, Records of Decision, and Other Remedy Selection Documents** 📖 *http://www.epa.gov/superfund/resources/remedy/rods/index.htm*

  This document provides recommended formats and content for Superfund remedial action decision documents, clarifies roles and responsibilities of regulatory agencies and stakeholders in the remedy selection process, and explains how to address changes made to proposed and selected remedies.

- **Revisions to OMB Circular A-94 on Guidelines and Discount Rates for Benefit-Cost Analysis (OSWER Directive 9355.3-20)** 🏛 📖 *http://www.epa.gov/superfund/*

  Contains USEPA policy on the use of discount rates for RI/FS cost analyses.

- **Presumptive Remedies** 🏛 📖 🛠 *http://www.epa.gov/superfund/resources/presump/index.htm*

  In an effort to streamline investigations and remedy selection, presumptive remedy guidance has been or will be developed for volatile organic compounds in soil, municipal landfills, metals in soils, wood treaters, and contaminated groundwater.

- **National Oil and Hazardous Substances Pollution Contingency Plan (NCP)** 🏛 📖
  http://www.epa.gov/docs/epacfr40/chapt-I.info/subch-J/

  Contains regulatory requirements for the RI/FS process (Title 40 Code of Federal Regulations, Part 300, Subpart E, Section 300.430).

Exhibit A-1 (cont.)
Internet Resources – Government

USEPA OSWER *http://www.epa.gov/swerrims/*

The Office of Solid Waste and Emergency Response (OSWER) develops guidelines and standards for the land disposal of hazardous wastes and for underground storage tanks. OSWER furnishes technical assistance in the development, management and operation of solid waste activities and analyzes the recovery of useful energy from solid waste. In addition, OSWER has undertaken the development and implementation of a program to respond to abandoned and active hazardous waste sites and accidental release (including some oil spills) as well as the encouragement of innovative technologies for contaminated soil and groundwater. OSWER resources include:

- **Federal Facilities Restoration and Reuse** *http://www.epa.gov/swerffrr/*
- **Solid and Hazardous Waste** *http://www.epa.gov/epaoswer/osw/index.htm*
- **Brownfields** *http://www.epa.gov/swerosps/bf/*
- **Superfund** *http://www.epa.gov/superfund/index.htm*
- **Technology Innovation** *http://www.epa.gov/swertio1/index.htm*
- **Underground Storage Tanks** *http://www.epa.gov/swerust1/*

USEPA – Publications *http://www.epa.gov/epahome/publications.htm*

Provides access to USEPA technical and public information. Resources include:

- **USEPA – National Service Center for Environmental Publications (NSCEP)**
  http://www.epa.gov/ncepihom

  Formerly known as NCEPI, NSCEP is a central repository for all EPA documents with over 5,500 titles in paper and/or electronic format, available for free distribution. The web site contains the National EPA Publications Catalog where documents can be browsed and ordered online.

- **National Environmental Publications Internet Site (NEPIS)**
  http://www.epa.gov/ncepihom/nepishom

  EPA's largest electronic documents site allows you to search view and print, including full images of all original pages and full-text, from a collection of over 7,000 archival and current documents. This collection may include documents that are no longer available in print form.

USEPA SITE Program *http://www.epa.gov/ORD/SITE*

USEPA's Superfund Innovative Technology Evaluation (SITE) Program encourages the development and implementation of innovative treatment technologies for hazardous waste site monitoring and remediation. The SITE program gathers engineering and cost data to assess the performance of treatment technologies. The information provided is intended to assist in evaluating and screening potential remediation technologies and in selecting a remedial alternative.

- **SITE Reports** *http://www.epa.gov/ORD/SITE/reports*

  This page provides links to SITE Reports including general reports, demonstration program reports, and emerging technology program reports.

Symbol Key: Policy Technical $ Cost Software/Database Publication

Exhibit A-1 (cont.)
Internet Resources – Government

USEPA Office of Research and Development 🕮 🛠 *http://www.epa.gov/ORD*

The USEPA's web site for research and development provides information pertaining to environmental and human health problems. The Office of Research and Development (ORD) focuses on the advancement of scientific research and the implementation of cost-effective technologies. ORD labs include the National Risk Management Research Lab, which includes:

- **Technology Transfer** 🕮 *http://www.epa.gov/ttbnrmrl/*

  Technology Transfer contains publications including guides, handbooks, summary reports and seminars on pollution prevention, monitoring, and treatment technologies.

USEPA – Office of Underground Storage Tanks 🕮 🏛 *http://www.epa.gov/swerust1/index.htm*

EPA's Office of Underground Storage Tank's (OUST) web site. OUST's goal is to provide current information relevant to the Federal underground storage tank (UST) program. The web site offers compliance assistance, UST publications, law/regulation information, and cleanup information. Resources include:

- **USEPA – Cleanup of UST System Releases** 🕮 🛠 *http://www.epa.gov/swerust1/cat/index.htm*

  This page contains UST cleanup resources, including general information, site characterization, remediation technologies, sampling, and monitoring.

U.S. Army Corp of Engineers (USACE)
http://www.usace.army.mil/

USACE - HTRW Center of Expertise 🏛 🕮 🛠 *http://www.environmental.usace.army.mil/*

The Hazardous, Toxic, and Radioactive Waste Center of Expertise (HTRW CX) provides general information regarding numerous technical areas including environmental regulations and laws, innovative technologies, environmental risk assessments, and environmental engineering. HTRW CX also provides general assistance to U.S. Army Corp of Engineer offices involved in environmental programs. The HTRW CX homepage contains technical information and guidance for cleaning up sites contaminated with hazardous, toxic, or radioactive waste. Technical resources include innovative technologies, process engineering, and costs. Resources include:

- **The TSDF Report** 🕮 🛠 $ *http://www.environmental.usace.army.mil/library/pubs/tsdf/tsdf.html*

  The Report on Treatment, Storage & Disposal Facilities (TSDF) for Hazardous, Toxic, and Radioactive Waste is designed to provide information, including costs, regarding the disposal of RCRA Subtitle C hazardous wastes and recycling of selected solid wastes.

- **Environmental Lessons Learned Program** 🕮 🛠
  http://www.environmental.usace.army.mil/library/lessons/lessons.html

  The Lessons Learned program was created to provide a means of identifying problem areas in the HTRW program; collect ideas on solutions, new technology and better methods; and to distribute those lessons learned.

- **Environmental Guidance Documents** 🕮 🛠
  http://www.environmental.usace.army.mil/library/guide/guide.html

  This page provides a link to environmental guidance documents including engineering manuals, pamphlets, technical letters, regulations, and guidance specifications.

- **Cost Engineering Resources** 🏛 🕮 🛠
  http://www.environmental.usace.army.mil/info/technical/cost/cost.html

  This page contains information regarding cost engineering resources of the HTRW CX. Links are provided to guidance, training materials, tools and databases, etc.

USACE – Cost Engineering Branch 🏛 📖 🛠 💾 **$** *http://www.hq.usace.army.mil/cemp/e/ec/ec_new.htm*

This is the home web site for the Cost Engineering and Programs Formulation Branch of the USACE. This branch is responsible for all aspects of cost engineering for the USACE. Links to various web sites related to cost information and other initiatives can be found on this web page. Resources include:

- **Economic Analysis for Military Construction** 🛠 💾 $
  http://www.hq.usace.army.mil/cemp/e/ec/econ/econ.htm

  This page contains links to economic analysis information including updated inflation and discount rates.
- **Regulations and Guidance Documents** 🏛 📖 🛠 *http://www.hq.usace.army.mil/cemp/e/ec/ec-regs.htm*

  This page contains links to regulation and guidance documents including:
  - Engineering and Design Cost Engineering Policy and General Requirements
  - Area Cost Factor Index
  - Military Construction Cost Index
  - Programming Cost Estimates for Military Construction
  - Economic Studies for Military Construction Design Applications

USACE – TRACES 📖 💾 🛠 **$** *http://www.hnd.usace.army.mil/traces/*

TRACES is the Tri-Services umbrella linking all automated cost engineering systems and their associated databases. Contained within this web site are links to information on various modules and other sources of cost information. Check the following sites for more specific information:

- **Micro Computer Assisted Cost Engineering System (MCACES)** 💾 🛠 $
  http://www.hnd.usace.army.mil/traces/mcaces.asp

  MCACES is a multi-user software program used for the preparation of detailed construction cost estimates for military, civil works, and HTRW programs.
- **Historical Analysis Generator (HAG)** 💾 🛠 $ *http://www.hnd.usace.army.mil/traces/hag.asp*

  The Historical Analysis Generator (HAG) is a software tool for analyzing and reporting historical cost data of past construction projects. The tool was developed by Building Systems Design, Inc. for the Tri-Service Cost Engineer Committee.
- **Life Cycle Cost (LCC)** 💾 🛠 *http://www.hnd.usace.army.mil/traces/lcc.asp*

  The Life Cycle Cost (LCC) module is a DOS-based stand-alone program that provides cost engineers with the capability of developing life cycle cost analyses.

USACE – Publications 📖 🛠 *http://www.usace.army.mil/inet/usace-docs/*

The collection of publications on this web site is the repository for all official USACE engineering regulations, circulars, manuals, and other documents originating from USACE headquarters. Many of the publications can be downloaded in electronic format. These include:

- **Engineering Instructions EI 01D010: Construction Cost Estimates**
  http://www.hnd.usace.army.mil/techinfo/ei.htm

Internet Resources – Government

U.S. Department of Energy (USDOE)
http://www.doe.gov/

USDOE – Environmental Management (EM) 🏛 📖 🛠 💾 *http://www.em.doe.gov*

In 1989, the Office of Environmental Restoration (ER) was created within the newly established Office of Environmental Management (EM) to consolidate, centralize and promote the cleanup of contaminated waste sites and surplus facilities within the DOE Complex. The DOE Environmental Restoration Program is involved in assessment and cleanup activities at 132 sites throughout the United States and in Puerto Rico. Check the following sites for more specific information:

- **Pollution Prevention in the Environmental Restoration Program** 📖 🛠
  http://www.em.doe.gov/p2/index.html

  This web site offers tools, resources, and guidance to assist in environmental cleanup projects.

- **Environmental Restoration Lessons Learned** 📖 🛠 *http://www.em.doe.gov/lessons/index.html*

  The EM Lessons Learned program evaluates the lessons learned relevant to environmental management business and functional areas to improve efficiencies and effectiveness, reduce risk and waste, and accelerate remediation project closure.

- **Decommissioning of Facilities** 🏛 📖 🛠 *http://www.em.doe.gov/dd/index.html*

  This page provides information on policy and guidance, a downloadable version of the Decommissioning Benchmarking Study, and links to site-specific decommissioning pages and lessons learned.

- **Cost & Performance Document** 📖 🛠 *http://www.em.doe.gov/costperf/index.html*

  The purpose of this DOE document is to facilitate the use of consistent procedures to document cost and performance information for environmental cleanup projects.

USDOE – EM – Applied Cost Engineering 📖 🛠 *http://www.em.doe.gov/aceteam/*

The Environmental Restoration (ER) Applied Cost Engineering (ACE) Team was established to promote continuous cost improvements through dissemination of cost engineering tools, methods, techniques, best practices, and lessons learned. Resources include:

- **Cost Engineering Links** 📖 🛠 *http://www.em.doe.gov/aceteam/links.html*

  This page provides links to cost engineering resources on the Internet.

USDOE – EM – Remedial Action Program Information Center (RAPIC) 🛠 💾 📖
http://www.em.doe.gov/rapic

RAPIC provides technical information support to the DOE Environmental Restoration (ER) Program. Information includes decontamination and decommissioning (D&D) and remedial action (RA) activities, technology development, and research at sites and facilities contaminated with radioactive and/or hazardous materials. Resources include:

- **Environmental Restoration Document Information System (ERDIS)** 📖
  http://www.em.doe.gov/rapic/6erdis.html

  The Environmental Restoration Document Information System (ERDIS), is an online document locator resource sponsored by the USDOE Office of Environmental Restoration.

Symbol Key: 🏛 Policy 🛠 Technical $ Cost 💾 Software/Database 📖 Publication

Exhibit A-1 (cont.)
Internet Resources – Government

USDOE –EM – Preferred Alternatives Matrices (PAMs) 🕮 🛠 *http://www.em.doe.gov/define*

The DOE's Preferred Alternatives Matrices provide information, background and descriptions of commercially available soil and groundwater remediation technologies. PAMs evaluate the available technologies ranking them on the basis of performance, risk of technology failure, and cost. The goal of this effort is to implement "the right technology, at the right time, at the right site."

USDOE – Environmental Technology Cost-Savings Analysis Plan 🛠 🖫 $
http://www.lanl.gov/projects/etcap/home.html

This web site contains information about the Environmental Technology Cost-Savings Analysis Project (ETCAP), sponsored by Los Alamos National Laboratory (LANL). This compendium provides a representative sample of cost information for environmental remediation technologies used in the treatment of hazardous, radioactive, and mixed waste. Data was gathered from a variety of sources and summarized herein to provide actual cost summaries or engineering cost estimates, site characteristics, and comments detailing remedial projects.

USDOE – National Energy Technical Laboratory 🛠 *http://www.netl.doe.gov/*

The National Energy Technical Laboratory (NETL) performs, procures, and sponsors technical research, development, and demonstration to advance technology into the commercial marketplace, thereby benefiting the environment. Their web site contains links to information on environmental projects and innovative technologies. The NETL was formerly known as the Federal Energy Technology Center (FETC).

U.S. Department of Defense

U.S. Air Force Civil Engineer Support Agency (AFCESA) 🛠 $ 🕮 🖫 *http://www.afcesa.af.mil/*

The Air Force Civil Engineer Support Agency provides tools, practices and professional support to maximize Air Force civil engineer capabilities in base and contingency operations. AFCESA consists of four directorates: Operations Support, Technical Support, Contingency Support; and Civil Engineer Maintenance, Inspection and Repair Team - Field Support. The Civil Engineering division of the Technical Support Directorate provides expertise in cost estimating; structural, water, wastewater, drainage and pavement systems; as well as in airfield marking, arresting and barrier systems. Resources include:

- **Cost Engineering Program** 🛠 $ 🕮 🖫
  http://www.afcesa.af.mil/Directorate/CES/Civil/CostEngr/CostEngr.htm

  The AFCESA Cost Engineering Program develops and maintains methodologies, cost models, and associated databases to estimate and analyze construction, environmental, and life cycle costs of Air Force facilities. Links to automated tools and guides/handbooks are provided on the web site.

Exhibit A-1 (cont.)
Internet Resources – Government

Other or Interagency

Federal Remediation Technologies Roundtable (FRTR) 🕮 🛠 🖫 $ *http://www.frtr.gov/*

The Federal Remediation Technologies Roundtable (FRTR) is an interagency working group seeking to build a more collaborative atmosphere among the federal agencies involved in hazardous waste site remediation. By providing such opportunities, the Roundtable hopes to identify and publicize more efficient, cost-effective solutions to the Federal government's hazardous waste challenges. Members include major developers and users of these technologies: Department of Defense, U.S. Army, U.S. Army Corps of Engineers, U.S. Navy, U.S. Air Force, U.S. Department of Energy, Department of the Interior, and the U.S. Environmental Protection Agency. Check the following sites for more specific information:

- **Cost and Performance Reports** 🕮 🛠 $ *http://www.frtr.gov/cost/*

  This page presents case studies and abstracts containing available cost and performance information for full-scale remediation efforts and numerous large-scale demonstration projects.

- **Environmental Cost Engineering Committee (EC2)** 🕮 🛠 $ *http://www.frtr.gov/cost/info/ec2.html*

  This page provides information on the work of the interagency EC2 group, including newsletters, listing of projects, and work products. Includes links to the Historical Cost Analysis System (HCAS) and the HTRW remedial action (RA) and operation and maintenance (O&M) work breakdown structures:

  HCAS *http://www.frtr.gov/cost/ec2/HCAS_OVERVIEW.htm*

  HTRW RA and O&M WBS *http://www.frtr.gov/cost/ec2/wbs1.html*

- **Remediation Technology Infobase** 🕮 🛠 *http://www.frtr.gov/publications/infobase98.html*

  This page contains a list of resources for information on Federal cleanup programs and remediation technologies.

- **Technology Demonstration** 🕮 🛠 *http://www.frtr.gov/demonstration.html*

  This page contains links to various technology demonstration projects.

- **Technology Development** 🕮 *http://www.frtr.gov/techdev/index.html*

  This page contains links to environmental technology resources on the Internet.

- **Remediation Screening Matrix** 🕮 🛠 $ *http://www.frtr.gov/matrix2/top_page.html*

  The Treatment Technologies Screening Matrix is a comprehensive guide intended to screen and evaluate candidate technologies for environmental cleanup projects and used to assist in selecting a remedial alternative. The guide incorporates performance and cost data allowing the user to screen for potential treatment technologies and to assign a relative probability of success. The guide can be accessed using a table of contents, screening matrix, or a search engine.

- **Sampling & Analysis Matrix** 🕮 🛠 $ *http://www.frtr.gov/site/*

  The sampling and analysis matrix assists in choosing cost-effective site characterization technologies so that the impact on human health and the environment can be properly evaluated.

- **Publications** 🕮 *http://www.frtr.gov/pubs.html*

  This page provides a list of FRTR publications.

Symbol Key: Policy 🛠 Technical $ Cost 🖫 Software/Database 🕮 Publication

Exhibit A-1 (cont.)
Internet Resources – Government

Groundwater Remediation Technologies Analysis Center (GWRTAC) 🕮 🛠 $ *http://www.gwrtac.org*

The Groundwater Remediation Technologies Analysis Center (GWRTAC) compiles, analyzes, and disseminates information on innovative groundwater remediation technologies. The data contains information on past performance, cost, and applicability. The information provided is intended to assist in evaluating and screening potential remediation technologies and in selecting a remedial alternative. Resources include:

- **Vendor Information** 🕮 🛠 *http://www.gwrtac.org/html/vendors.html*

  This page provides vendor information for groundwater remediation technologies.

- **Technical Reports** 🕮 🛠 $ *http://www.gwrtac.org/html/techdocs.html*

  This page contains groundwater and environmental technical reports available online.

Remedial Technologies Development Forum (RTDF) 🕮 🛠 *http://www.rtdf.org*

The purpose of the RTDF is to "identify what government and industry can do together to develop and improve the environmental technologies needed to address their mutual cleanup problems in the safest, most cost-effective manner." The RTDF consists of several action teams including:

The Bioremediation Consortium
The Lasagna Partnership
INERT Soils – Metal Team
Phytoremediation of Organics Team
Permeable Reactive Barriers Team
In-Situ Flushing Team
Sediments Remediation Team

Detailed information on each of these teams can be found on this web site, including technical documents, processes, and other resources.

Global Network of Environment and Technology (GNET) 🕮 🛠 *http://www.gnet.org*

GNET provides daily news and up-to-date information on current environment and technology issues. Resources include:

- **TechKnow** 🕮 🖫 🛠 $ *http://www.techknow.org*

  TechKnow is GNET's free interactive database of innovative remediation and environmentally sustainable technologies.

Johnson Space Center - Cost Estimating Group 🕮 🛠 🖫 *http://www.jsc.nasa.gov/bu2/index.html*

This is NASA's cost estimating web site, containing resources, publications, software and tools pertaining to cost estimating.

Appendix B
Cost Adjustment Factors

This appendix provides information on how to calculate and apply cost adjustment factors, including those for escalation, area cost, and health and safety productivity.

Escalation

Costs that have been derived from sources that are one year old or more should be updated or escalated to the base year. This can be done using the following equation:

$$C_b = C_o (F_b / F_o)$$

where C_b is the base year or current cost, C_o is the old cost, F_b is the base year or current index factor, and F_o is the index factor for the old cost.

Escalation indexes are available from both private and public sources. Most are published on a monthly or annual basis. An example index is Engineering News Record's (ENR) building cost index, which is based on a 20-city average of labor rates for bricklayers, carpenters, and iron workers plus material costs for structural steel, portland cement, and lumber using a certain number of labor hours and material quantity. Monthly factors for this index, from January 1978 to July 2000, are shown in Exhibit B-1. The index is also available at *http://www.enr.com/cost/costbci.asp*.

Exhibit B-1

Area Cost Factors

Costs that are based on national averages or on geographic locations other than the site should be adjusted for location using area cost factors (ACFs). This can be done using the following equation:

$$C_s = C_o (F_s / F_o)$$

where C_s is the cost for the site location, C_o is the cost based on other location, F_s is the area cost factor for the site, and F_o is the area cost factor for other location.

ACFs are available from both private and public sources. Most are updated yearly for their publication. National and state averages for ACFs (current as of March 10, 2000), as maintained by the USACE for military construction use, are provided in Exhibit B-2 below, as an example. These factors are based on local construction costs of labor, material, and equipment, and other factors such as weather, climate, seismic, mobilization, overhead and profit, labor availability, and labor productivity. The most current ACFs can be downloaded through the USACE Cost Engineering Branch website at *http://www.hq.usace.army.mil/cemp/e/es/pax/321/321.pdf* .

Exhibit B-2
USACE Area Cost Factors as of March 10, 2000

Location	Area Cost Factor	Location	Area Cost Factor
Alabama	0.85	Nebraska	0.94
Alaska	1.61	Nevada	1.14
Arizona	0.98	New Hampshire	1.05
Arkansas	0.87	New Jersey	1.18
California	1.18	New Mexico	1.01
Colorado	1.03	New York	1.23
Connecticut	1.05	North Carolina	0.85
Delaware	1.02	North Dakota	1.04
Florida	0.87	Ohio	0.99
Georgia	0.85	Oklahoma	0.87
Hawaii	1.48	Oregon	1.10
Idaho	1.06	Pennsylvania	1.03
Illinois	1.15	Rhode Island	1.06
Indiana	0.99	South Carolina	0.87
Iowa	1.06	South Dakota	0.95
Kansas	0.93	Tennessee	0.87
Kentucky	0.94	Texas	0.82
Louisiana	0.89	Utah	1.03
Maine	1.06	Vermont	0.92
Maryland	0.89	Virginia	0.92
Massachusetts	1.12	Washington	1.07
Michigan	1.17	West Virginia	0.95
Minnesota	1.07	Wisconsin	1.14
Mississippi	0.87	Wyoming	0.99
Missouri	0.97	Washington, D.C.	0.95
Montana	1.13	National Average	1.00

Health and Safety Productivity

Unless effects are already accounted for, factors that reflect decreased productivity due to required health and safety levels of protection should be applied to costs for labor and construction equipment used in a crew makeup. The levels of protection, which are determined based on the hazards to workers that might be present at a hazardous waste site, are classified as follows:

- Level A: Fully encapsulating vapor-tight suit with full-facepiece, self-contained breathing apparatus (SCBA) or supplied-air respirator.
- Level B: Totally encapsulating suit, not necessarily vapor-tight, with full-facepiece SCBA or supplied-air respirator.
- Level C: Chemical protective, full body suit with full-face, canister air-purifying respirator.
- Level D: Basic work uniform (i.e., coveralls, gloves, hardhat, boots, faceshield or goggles). Modified Level D adds a chemical protective, full body suit (i.e., Level C without respirator).

Factors associated with decreased productivity due to protective equipment and clothing as described above include restricted mobility, heat stress requiring break time, and time for safety meetings, suit-up, suit-down, decontamination, and air tank changes. All of these factors reduce crew production rates.

As an example, the productivity factors used by the USACE for Hazardous, Toxic, and Radioactive Waste (HTRW) projects are shown in Exhibits B-3 and B-4, for light and heavy work, respectively, as published in *Construction Cost Estimates* (USACE 1997). The factors in these exhibits are based on a productivity study conducted in 1994 and are applied to crew production rates in the Unit Price Book (UPB), which are based on "clean" site conditions, to develop adjusted rates based on the health and safety level of protection. The decreased production rate has an impact on cost by either increasing the time required to complete the activity or prompting the cost engineer to add crews.

As an approximate method (e.g., development of cost estimate during FS), the inverse of these factors can be applied to the unadjusted cost of an element to reflect decreased productivity for that item. This can be done using the following equation:

$$C_l = C_o (1 / F_l)$$

where C_l is the cost for the assumed level of protection, C_o is the cost unadjusted for level of protection, and F_l is the productivity factor from Exhibit B-3 or B-4.

The productivity factors do not apply to material costs, treatment equipment costs, or other costs that do not include crew costs.

Exhibit B-3
HTRW Productivity Factors - Light Work

Notes: 1. Standard Losses account for all time losses independent of temperature variations. They include safety meetings, instructions, donning / doffing PPE, decontamination, switching air supply / filters, monitoring delays, and cleanup.

2. Scheduled / Heat Stress Breaks account for all paid rest periods per manday.

3. Dexterity Losses are based on subjective opinions of the percentage that PPE slows down a normal worker because of factors such as discomfort, clumsiness, weight, and restricted breathing and communication. The number of minutes actually worked is reduced by the percentage representing the average response for that particular PPE level.

4. Values for A, B, and C were derived by averaging the survey responses for each PPE level. Responses that varied greatly from the average were subject to omission at the author's discretion.

5. Total Paid Time = 480 minutes

6. 50 min delay on clean site = 10 min. safety meeting & instructions + 10 min. cleanup + 30 min. breaks

7. Calculations:
   - D = A + B + C
   - E = 480 - D
   - F = 480 - 50
   - G = E / F

   U/M = Unit of Measure
   MD = Man-Day
   Min = Minutes
   T = Temperature Farenheit

8. Level A protection is used in extreme emergency situations only. Productivity factors for Level A should be used with caution because they were extrapolated from 2 data points.

Appendix C
Example Cost Templates

The following pages provide example summary sheets for capital costs, annual O&M costs, periodic costs, present value analysis, and sensitivity analysis. Also provided is example cost worksheet that can be used to calculate and provide backup for cost element or sub-element unit costs used in an estimate.

☐	Subcontractor Overhead and Profit	_____
☐	Prime Contractor Overhead and Profit	_____

Appendix D

Glossary

Capital Costs: Expenditures required to construct a remedial action. They are exclusive of costs required to operation or maintain the action.

Constant (Real) Dollars: Observed dollar values that are not affected by general price inflation. Typically used during FS cost estimating to compare relative prices over time.
