Contingency: An amount added to a cost estimate to cover costs associated with unknowns, unforeseen circumstances, or unanticipated conditions that are not possible to evaluate from the data on hand at the time the estimate is prepared. Can include both scope (design) contingency, to cover costs due to scope changes during design, and bid (construction) contingency, to cover unknown costs associated with constructing or implementing a given project scope.

Cost Element: An activity identified for a remedial alternative that is used to estimate both capital, annual O&M, or periodic costs and help define the project. Cost element categories include construction activities, O&M activities, professional/technical services, and institutional controls.

Cost Engineering: The practice of total cost management over the life cycle of a project, facility, or manufacturing operation. Components include cost estimation, cost control, project management, planning, scheduling, and profitability analysis.

Cost Estimate: An evaluation of all the costs of the elements of a project or effort as defined by an agreed-upon scope.

Discount Rate: The interest rate used in calculating the present value of expected future costs. A nominal discount rate is an interest rate that has not been adjusted for any change in the general price level (inflation). Nominal interest rates are those that usually may be observed in the market, such as the published rate on a savings account or a bond. Nominal interest rates should be used to discount costs that are in current, or nominal, dollars. A real discount rate is an interest rate that has been adjusted to account for the effect of expected or actual inflation. Real interest rates can be approximated by subtracting the expected or actual inflation rate from a nominal interest rate. Real interest rates should be used to discount costs that are in constant, or real, dollars, which is the typical situation for FS present value analyses.

Life Cycle Cost: The total cost across the life span of a project, including design, construction, operation and maintenance, and closeout activities. Includes initial capital costs plus any continuing costs of operation and maintenance. For the purposes of this guide, excludes costs prior to design, such as investigation and study costs, and excludes government or program management costs.

Nominal (Current) Dollars: Values as they are observed in the market when transactions occur. Nominal dollars are real dollars that have been escalated to reflect the effects of inflation.

O&M Costs: Post-construction costs necessary to ensure continued effectiveness of a remedial action. Includes both short-term O&M and long-term O&M costs. Most O&M costs are estimated on an annual basis.

Periodic Costs: Capital or O&M costs that occur only once every few years or only once during the entire project timeframe. Because of their periodic nature, these costs are usually considered separately in the estimating process from initial capital or annual O&M costs.

Present Value: The present value of a future investment or payment that is calculated using a particular discount or interest rate. Total present value is the amount of money, which, if invested in the current year, would be sufficient to cover all the costs over time associated with a project.

Sensitivity Analysis: A type of uncertainty analysis that measures the project impact of changing one or more input values. For remedial alternative cost estimates, sensitivity analyses are typically completed for those factors that have a relatively high degree of uncertainty and that, with only a small change in their value, could significantly affect the overall cost of the alternative.

Unit Cost: A cost per unit of measure that is usually multiplied by a quantity to estimate the cost of an element or sub-element within the cost estimate of a remedial alternative. A unit cost is typically adjusted for decreased crew productivity, escalation to base year, geographic location, contractor markups (e.g., overhead, profit), and other factors, depending on the source of cost data (e.g., quotes, cost references, historical data).

GEOLOGY AND GROUND-WATER RESOURCES OF OUTAGAMIE COUNTY, WISCONSIN

By E. F. LeRoux

ABSTRACT

Outagamie County is in east-central Wisconsin. It has no serious ground-water problem at present, but the county is important as a recharge area for the principal aquifers supplying water to Brown County and industrial Green Bay to the east.

The county is covered by glacial drift and lake deposits of the Wisconsin stage of glaciation. In the northwestern quarter of the county these deposits rest upon Precambrian crystalline rocks; throughout the remainder of the county they are underlain by sandstone, limestone, dolomite, and shale of Cambrian and Ordovician age. Where they are sufficiently thick, and where more productive formations are absent, glacial sand and gravel are an important source of ground water. The major sources, however, are the St. Peter sandstone, of Ordovician age, and the sandstones of the Upper Cambrian series. The Precambrian crystalline rocks, which underlie all the county, yield little or no water to wells.

The regional dip of the Paleozoic bedrocks is 25 to 30 feet per mile eastward and southeastward. There are no major folds, but the thickness of each geologic unit may change from place to place because of predepositional or postdepositional erosion. There is no conclusive evidence of major faulting in the area.

Ground water in Outagamie County occurs under both water-table (unconfined) and artesian (confined) conditions. The source of the ground water is precipitation which falls on the surface and percolates downward into the underlying permeable materials. Regional movement of ground water in the eastern third of the county is controlled by the bedrock structure, and the discharge is toward the east and south. Throughout the rest of the county the movement of water is controlled mainly by bedrock and surface topography, and the water moves toward the streams and bedrock valleys.

Water-level fluctuations follow definite patterns. Where the effects of pumping are at a minimum, water levels reach a high in April or May, decline through the summer months owing to natural discharge, and lack of recharge, and do not begin to recover until after the ground thaws in the spring. In areas of heavy pumping where this pattern is distorted, the lowest water levels occur in the early fall and recoveries begin in October or November after the period of heaviest pumping.

Pumpage in the county was estimated to be about 9.0 million gallons per day (mgd) in 1951 and 1952. Nearly half of this was for industrial, commercial, and public-supply use along the Fox River. Wells, most of which are drilled by the cable-tool method, range in diameter from 3 to 16 inches and in depth from 10 or 20 feet to 804 feet. In the alluvium and glacial drift 1¼- to 2½-inch driven wells are common.

Pumping tests were made to determine the hydraulic characteristics of the aquifers at Seymour, Appleton, and Hortonville. The average coefficient of transmissibility at Seymour is about 18,000 gpd per foot; at Appleton it is about 19,000 gpd per foot. The coefficients of storage are 0.00022 and 0.00015 at Seymour and Appleton, respectively. Movement of ground water out of the county, assuming an average transmissibility of 18,000 gpd per foot, was calculated to be more than 10 mgd toward the southeast.

The ground water differs greatly in chemical quality from well to well, but it is generally a very hard calcium magnesium bicarbonate water, some of it high in iron. To aid in determining the source of well waters, 22 chemical analyses were plotted on a logarithmic diagram to obtain characteristic patterns for waters from several geologic sources.

INTRODUCTION

PURPOSE AND SCOPE

The study of ground-water conditions in Outagamie County described in this report was made by the U. S. Geological Survey in cooperation with the University of Wisconsin. The report includes a discussion of the geology of the area, the occurrence of ground water, the hydrologic properties of the aquifers, and the chemical quality of the water. Hydrologically the county is important as a recharge area for the principal aquifers underlying Brown County and Green Bay to the east. The present study is, in part, supplemental to the investigation of Brown County published as U. S. Geological Survey Water-Supply Paper 1190. There is no serious ground-water problem at present in Outagamie County, and this report is presented as a compilation and summary of available data for use in conjunction with the expected expansion of agriculture and industry in the county.

METHOD OF INVESTIGATION

A canvass of wells and systematic collection of other data were begun in 1951 by W. C. Walton. The investigation was continued and expanded in 1952 and 1953 by V. T. McCauley. The geology was mapped and the fieldwork was completed by the author in 1954. The work was done under the general direction of A. N. Sayre, chief of the Ground Water Branch of the U. S. Geological Survey, and under the immediate supervision of W. J. Drescher, district engineer.

Water levels in several wells have been measured at intervals since 1947 as a part of a Statewide program, and an automatic water-level recorder has been in operation on well Ou 2 since December 1946. A continuing program of water-level measurements was begun in 1952. In April 1949 a pumping test was made at Seymour to determine the hydrologic properties of the water-bearing material at that location. This was followed by a test at Hortonville in 1953 and another in Appleton in 1954. The results of these tests were used to estimate rates of movement of ground water and to predict trends of the water levels in relation to pumping.

Reconnaissance geologic mapping of the county was done on Wisconsin Land Inventory maps at a scale of about 1 inch to the mile; most of the county has not been topographically mapped. Field mapping was based on examination of outcrops and land forms. Subsurface control is from drillers' logs and from logs based on examination of drill cuttings by F. T. Thwaites of the Wisconsin Geological Survey.

ACKNOWLEDGMENTS

The success and value of a study such as this depend in large part on the cooperation and assistance of local persons. The willing cooperation of well owners, well drillers, civil officials, and private citizens is greatly appreciated. The pumping tests would not have been possible without the cooperation of Walter Muehle, superintendent of the Seymour Water Department; Arthur Dunn, Hortonville water superintendent; Walter Schroder, president of the Fox Valley Canning Co.; and W. Segar of the Badger Consolidated Cooperative Dairy.

The author wishes especially to thank F. T. Thwaites, Wisconsin Geological Survey, for the use of his field notes and G. F. Hanson, State Geologist, for his review of the report.

Members of the Bureau of Sanitary Engineering, Wisconsin State Board of Health, contributed greatly to the report by giving access to files of well records and pumpage data. Chemical analysis of water samples, which were collected by members of the U. S. Geological Survey, was made by chemists of the Wisconsin State Laboratory of Hygiene.

PREVIOUS REPORTS

Martin (1932) presents a fairly complete list of early reports on the geology of Wisconsin. Reports by Chamberlin (1877), Weidman and Schultz (1915), and Thwaites (1943) contain much information pertinent to the geology and ground-water resources of Outagamie County. A soil survey by Whitson and others (1921) and a discussion of the geography of the Fox River valley by Whitbeck (1915) provide additional historical and geographical information.

DESCRIPTION OF THE AREA

LOCATION AND EXTENT

Outagamie County is in east-central Wisconsin, north of Lake Winnebago and southwest of Green Bay, between latitudes 44°14′ and 44°36′ N. and longitudes 88°11′ and 88°44′ W. (pl. 1). The county is rectangular, about 27 miles long, east-west, and 24 miles wide; it has an area of about 646 square miles. Appleton (1950 pop. 34,010) is the principal city and the county seat.

CULTURE

In 1950 the county's population was 81,722. About 61 percent of the population lives in the urban areas along the Fox River, about 20 percent on farms, and about 19 percent in villages.

More than 90 percent of the land was in farms in 1949. The farms are small, averaging about 109 acres as compared with 138 acres for the State. Seventy-eight percent are classed by the U. S. Census as dairy farms, and 89 percent of the farm income is from livestock and livestock products. The county ranks 7th in milk production (412,500,000 lbs. in 1953) and 13th in cheese production (15,587,000 lbs. in 1953) in the State.

Industrial growth has been due almost entirely to the abundant water and power furnished by the Fox River. The world's first hydroelectric central station started operation in Appleton in 1882, and electricity has played an important role in industrial development since that time. The principal industries are associated with food processing, and knitting, and the manufacture and processing of paper, wood products, metal products, and machinery. Closely associated with the growth and development of the area is Lawrence College, at Appleton, founded in 1847, 10 years before the city was incorporated.

TOPOGRAPHY

Only small, isolated areas in Outagamie County have been covered by adequate topographic mapping. The well altitudes and rock-outcrop altitudes used in this report were obtained with an aneroid altimeter using U. S. Coast and Geodetic Survey and U. S. Geological Survey bench marks for control. The highest altitude obtained by this method is 1,015 feet above mean sea level at the top of a drumlin along the north edge of sec. 33, T. 22 N., R. 16 E., about 3.5 miles east of Hortonville. This hill is probably the highest point in the county, although several other drumlins near Hortonville reach altitudes of more than 1,000 feet. The lowest measured well altitude (Ou 43) is 620 feet above mean sea level in Kaukauna. However, the lowest point in the county is about 600 feet where the Fox River enters Brown County, about 4.5 miles northeast of Kaukauna.

The county may conveniently be divided into three topographic units. The flat northwestern quarter, bounded on the south and east by the escarpment of the cuesta formed by rocks of the Prairie du Chien group, is covered by glacial-lake deposits and Recent flood-plain deposits. Along both sides of the Fox River is another area of relatively flat but well-drained land, formed by glacial-lake deposits. The remainder of the county is a gently rolling countryside of drumlins, moraines, and occasional small scarps and cliffs of bedrock exposed through thin glacial drift.

DRAINAGE

Essentially all of Outagamie County, except for the land drained by Duck Creek, is included within the Fox River drainage basin.

From the northern boundary of the county, near Leeman, the Wolf River flows parallel to the escarpment formed by the Prairie du Chien group southward through Shiocton to a point about 3 miles northeast of Hortonville, where it turns abruptly to the west and flows through New London. It is joined at Shiocton by the Shioc River, which drains the area north and west of Seymour, and at New London by the Embarrass River, which drains the extreme northwestern part of the county. The drainage basin of the Wolf River above New London has an area of about 2,240 square miles, about 400 square miles being in Outagamie County. The average daily discharge at New London is 1,793 cubic feet per second (cfs) (Paulsen and others, 1952). The Wolf River is a slow-moving, meandering stream as it traverses the flat, poorly drained northwestern quarter of the county. The gradient from Shawano, 47 miles upstream, to New London averages only about 0.8 foot per mile (Smith, 1908). From New London the river flows southwestward through Waupaca County and into Winnebago County, where it joins the Fox River, which flows into Lake Winnebago at Oshkosh.

The lower Fox River leaves the northwest corner of Lake Winnebago at Neenah-Menasha, about 5 river miles south of Appleton. In its 35-mile course to Green Bay it falls about 4.8 feet per mile (Smith, 1908). However, most of this fall is over rapids in the reach from Appleton to Kaukauna, where it drops nearly 10 feet per mile. At Rapide Croche Dam, about 12 miles downstream from Appleton, the average discharge is 4,242 cfs (Paulsen and others, 1952) from a drainage area of 6,150 square miles.

The remainder of the county is drained by Duck Creek, which flows generally south from Seymour, about 6.5 miles north of Little Chute, it turns abruptly to the northeast and flows between two prominent ridges out of the county and, 17 or 18 miles farther northeast, into Green Bay.

CLIMATE

The climate of Outagamie County is characterized by mild, humid summers and rather long, severe winters. The growing season averages 163 days at Appleton, 151 days at New London, and 134 days about 27 miles north of New London at Shawano. Four months of the year, December through March, have an average temperature below 32° F; the 5 months from May through September are generally free from frost (fig. 1). Average monthly temperatures range from a high of 70.9° F in July to a low of 16.2° F in January. The mean annual temperature is 43.6° F, which is 0.2° F above the annual mean for the

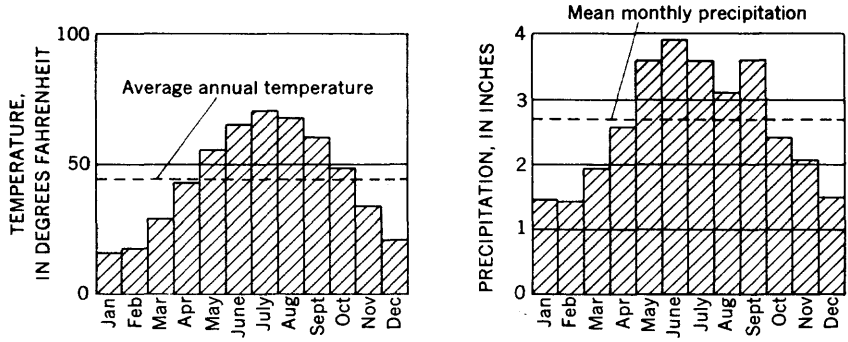

FIGURE 1.—Average monthly temperature and precipitation, Outagamie County, Wis. (Appleton, Green Bay, New London)

entire State. The average annual precipitation, including snow in the winter months, is 31.25 inches. The average ranges from 3.93 inches in June to 1.42 inches in February. Fortunately for agriculture, about 57 percent of the yearly precipitation falls during the growing season, May through September.

GEOLOGIC UNITS AND THEIR WATER-BEARING PROPERTIES

With the exception of the Precambrian granite, all the rock units discussed in the report and shown in table 1 are exposed at the surface in Outagamie County. The map showing bedrock geology (pl. 2) is based on the State geologic map (Bean, 1949). Modifications and changes were made in accordance with field observations and drillers' logs collected during the investigation.

PRECAMBRIAN ROCKS

The crystalline rocks of Precambrian age, which underlie all of Outagamie County, have been encountered in a number of wells throughout the area. They are usually reported to be pink, red, or gray coarse-grained granite or granite gneiss, which may or may not be weathered through the first several feet. Thwaites (1931) suggests that much of the weathered zone of kaolinitic clay, where present, may not be a product of subaerial weathering, but rather a product of alteration of the crystalline rocks by acidic ground water from the overlying sandstone. This theory is supported by the fact that some well drillers report a nongradational contact between the weathered zone and the overlying sandstone. No Precambrian rocks are exposed in Outagamie County. However, a prominent northwest-trending hill in Waupaca County, about 3 miles south-southwest of New London, is composed entirely of a moderate pink coarse- to medium-grained biotite granite intersected by numerous quartz veins.

TABLE 1.—*Description and water-bearing characteristics of geologic units in Outagamie County, Wis.*

System	Geologic unit	Maximum depth to top (feet)[1]	Maximum thickness (feet)[1]	Description		Water-bearing characteristics
				Drill cuttings [2]	Outcrop observations [3]	
Quaternary.	Recent river and swamp deposits.	0	?	----------	Silt, sand, and peat.	Not determined.
	Pleistocene deposits.	?	510	Glacial drift, mostly till; sand, clay, silt, gravel, boulders.	Glacial drift, mostly till, and lake clay. Moderate-red to dark-yellowish-orange silty clay; sand, gravel, silt, boulders.	Good yields where sufficiently thick. Flowing wells and seepage springs common. Only source of groundwater supply in northwest part of county.
Ordovician.	Maquoketa shale.	7	209	Shale, blue, dolomitic, calcareous; thin beds of shaly blue-gray dolomite.	Shale, light-bluish-gray, thin-bedded. Thin beds of dolomite.	Yields very small quantities of highly mineralized water to a few domestic and stock wells.
	Galena dolomite and Platteville formation, undifferentiated.	216	211	Dolomite, sandy, gray to bluish-gray. Sandstone, fine-to medium-grained, gray; usually near base of formation.	Dolomite, thin-bedded to blocky and massive. Greenish-gray to yellowish-gray; sandy, silty, oolitic in places.	Yields small amounts of water along bedding planes and from sandy zones.
	St. Peter sandstone.	424	171	Sandstone, fine- to coarse-grained, pink, gray, and white; some chert. Thin layers of sandy gray and red shale.	Sandstone, fine- to coarse-grained, well-rounded, soft, friable; banded pale-reddish-brown and grayish-orange, occasionally white.	Good yields, but limited by presence of shale and relatively small thickness of formation.
	Prairie du Chien group.	490+	235+	Dolomite, gray, pink, and red, commonly sandy and shaly; layers of chert. Sandstone, fine- to medium-grained, white. Shale, red and green.	Dolomite, usually massive, yellowish-gray; chert layers common. Occasional sandy and shaly zones.	Small quantities of water obtained from cracks and sandy zones.
Cambrian.	Upper Cambrian series.	490+	458+	Sandstone, very fine to coarse-grained; pink, white, gray, and red; occasionally shaly and dolomitic. Dolomite, soft, sandy, with red and greenish-gray dolomitic siltstone.	Sandstone, very fine to coarse-grained, well-rounded; interbedded soft, hard, and friable; pale yellowish-orange and white to medium-gray. Some pyrite.	Yields large amounts of water, especially from the lower portion which is less dolomitic.
Precambrian.		800		Granite, pink, gray, and red; weathered at the top.	Granite, coarse- to medium-grained, moderate-pink, biotitic. (Crops out in Waupaca County.)	Essentially impermeable. May yield some water from weathered and creviced zone.

[1] Based on well logs. [2] By F. T. Thwaites. [3] By E. F. LeRoux.

The crystalline rocks yield little or no water to wells. A very small amount might be obtained from cracks in the rock or from the weathered zone, but drilling usually ceases shortly after reaching granite.

PALEOZOIC ROCKS

CAMBRIAN SYSTEM

Upper Cambrian series.—Sandstones of Late Cambrian age (Dresbach sandstone, Franconia sandstone, and Trempealeau formation) are the principal source of water for industrial and public-supply wells in Outagamie County. They supply water to Seymour and Hortonville and to all the cities along the Fox River below Appleton. They are exposed in several places at the foot of the escarpment of the Prairie du Chien group (pl. 2) and in the Mosquito Hills, about 1½ miles east of New London. In outcrops the sandstones are very fine to coarse grained, ranging from pale yellowish orange to medium gray and white. Hard, well-cemented layers are interbedded with soft, friable layers. Some beds stand up well to weathering; others crumble and disintegrate rapidly. In drillers' logs (table 10) the section is reported as shaly, silty, and dolomitic in the upper part, grading into a fine- to medium-grained sandstone at the base.

A sample taken from an outcrop in the SE¼NE¼ sec. 4, T. 22 N., R. 15 E., had a remarkably symmetrical distribution of grain sizes (J. Lopez, written communication). The histogram in figure 2 shows

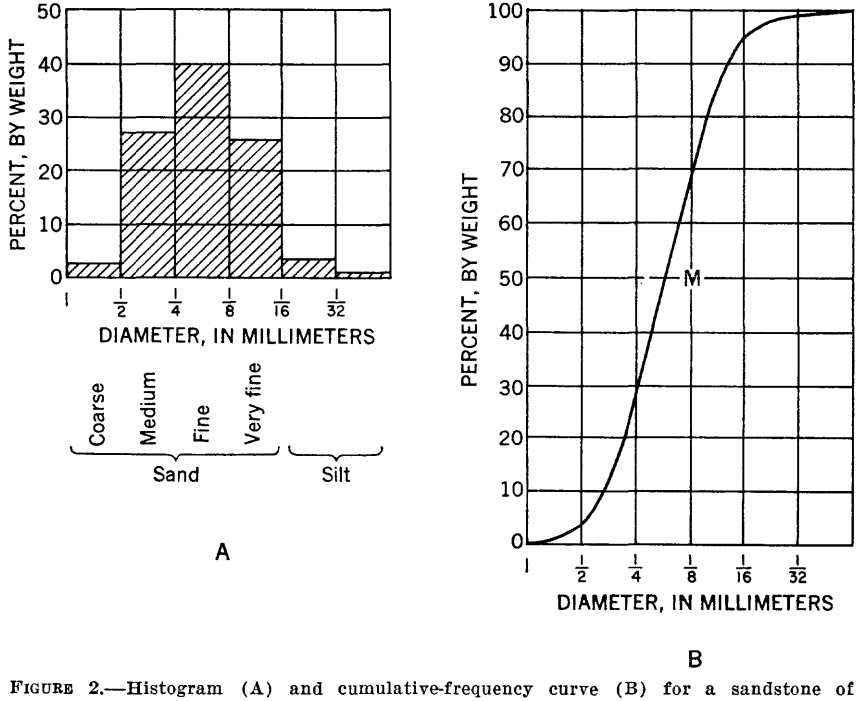

FIGURE 2.—Histogram (A) and cumulative-frequency curve (B) for a sandstone of Cambrian age, Outagamie County, Wis.

that about 40 percent of the grains were in the fine-sand range, the remainder being divided almost equally between the larger and the smaller sizes. The cumulative-frequency curve shows that the mean grain size is about $\frac{3}{16}$ mm (fine grained); it gives also a more exact picture of the gradation between grain size units in the sample.

Although the Upper Cambrian series is the most important aquifer in Outagamie County, a comparison of specific capacities and yield factors (tables 2 and 3) shows the St. Peter sandstone to have a much higher permeability. The specific capacity of a well (yield per unit of drawdown, generally expressed as gallons per minute per foot of drawdown) is an indication of both the water-yielding capacity of wells and the relative transmissibility of the water-bearing materials they penetrate. The yield factor (Poland and others) is an indication of the relative permeability of the water-bearing material. It is expressed as gallons per minute per foot of drawdown per 100 feet of aquifer penetrated. The specific capacity and yield factor of a well are representative of the water-bearing material within the area of influence of the well. In tests of short duration the area of influence is relatively small. As the well continues to pump, the area of influence expands and the specific capacity and yield factor may change, owing to changes in the character of the water-bearing material sampled by the expanding cone of influence. For this reason, comparisons between tests of equal length are the most consistent.

Table 2 summarizes the available data on specific capacity and yield factor for 16 wells. Wells Ou 19, 23, and 280 in Appleton have almost identical yield factors, as do the two wells in Seymour. The lower yield factors for the wells in Kimberly, Little Chute, and Kaukauna indicate lower permeability. Drillers' logs of these wells show that the water-bearing material is finer grained and contains more silt and siltstone than that penetrated by the wells in Appleton. The relatively high yield factors of the remaining wells may be due to their location near the outcrop area or may reflect the smaller dicharge and shorter duration of the tests.

ORDOVICIAN SYSTEM

Prairie du Chien group.—The Prairie du Chien group of Ordovician age, the Lower Magnesian of early reports, is composed of the Oneota dolomite, the New Richmond sandstone, and the Shakopee dolomite (Thwaites, 1923), but it was not subdivided in this investigation. It is best exhibited in the prominent escarpment which forms the southern and eastern boundaries of the flat northwestern quarter of Outagamie County. It is exposed also in many active quarries where rock is obtained for use as road material. An interesting feature of several of these quarries (that in the SE¼SE¼ sec. 17, T. 24 N., R. 17 E., for example) is the domelike structure that is revealed.

These domes are quite characteristic of the Prairie du Chien group. They are composed of concentric layers over a core of brecciated dolomite (Chamberlain, 1883).

TABLE 2.—*Specific capacity and yield factor of wells in the Upper Cambrian series*

Well no. Ou—	Specific capacity [a]	Yield factor [b]	Length of test (hrs)	Average discharge (gpm)	Thickness of aquifer penetrated (ft)	Location	Well diameter (in.)
1	7.4	2.7	24	421	[c] 276	Seymour	10
10	8.6	2.8	24	310	305	do	12

273	.9	1.6	4	20	[d] 58	do	6
280	29	5.8	10	1,200	[e] 500	Appleton	15

[a] Gallons per minute per foot of drawdown.

[b] $\frac{\text{Specific capacity} \times 100}{\text{Thickness of aquifer penetrated (feet)}}$

[c] Includes 65 feet of St. Peter sandstone which contributes water to the well.

[d] Includes 40 feet of hard, non-water-bearing sandstone. If this is not included the yield factor becomes 5.0.

[e] Includes 70 feet of St. Peter sandstone which contributes water to the well.

The weathered surface of the rock is pale brown to pale yellowish brown; fresh surfaces are yellowish gray. Sandy and shaly zones and layers of chert are exposed in some outcrops. Thwaites (1923) states that the presence of oolitic chert is a reliable marker of the Prairie du Chien group, as it has never been found in adjacent dolomite formations. In drillers' logs the rock is described as gray, pink, or red dolomite that is often sandy or shaly. Lenses of fine- to medium-grained white sandstone are found throughout the section, as are thin layers of red or green shale.

The dolomite is dense, and water is transmitted through vertical fractures and along bedding planes and solution channels. The sandstone lenses also supply some water to wells, but the unit as a

whole is not as productive as the overlying and underlying sandstone units. However, many domestic and stock wells obtain a small but adequate supply from the Prairie du Chien. Well Ou 278 was pumped at 12 gallons per minute for 2 hours, the water level lowering 2 feet. In a comparable test, well Ou 15, which taps both the Platteville formation and Galena dolomite and the Prairie du Chien group, yielded 150 gallons per minute but with a drawdown of 150 feet.

St. Peter sandstone.—The St. Peter sandstone of Ordovician age crops out at the base of escarpments topped by the Platteville formation and Galena dolomite or is buried by Pleistocene and Recent deposits in low, swampy areas. It is a soft, friable sandstone that usually weathers to a pale reddish brown. Fresh surfaces show a reddish-brown and grayish-orange banding and occasional zones of pure white sand. The well-rounded grains range in size from fine to coarse and appear well sorted. The drill cuttings are described as fine- to coarse-grained pink, gray, and white sandstone with some chert. Thin layers of sandy gray and red shale are disseminated throughout the section but usually are more common near the base.

The St. Peter sandstone is an important supplier of water to stock and domestic wells but it is absent in most wells in the industrial area along the Fox River. Table 3 shows that the relatively slight importance of the St. Peter as an aquifer in Outagamie County is a reflection of the thinness of the sandstone. Yield factors of 3 of the 4 wells tapping the St. Peter are considerably higher than those of wells tapping the Upper Cambrian series (table 2), showing that, were the St. Peter sandstone as thick and extensive as the Upper Cambrian series, it would easily surpass that series as an aquifer. The short duration of the tests cited in table 3 may account, in part, for the high yield factors, but similar tests of wells in the Upper Cambrian series do not give comparably high figures.

TABLE 3.—*Specific capacity aid yield factor of wells in the St. Peter sandstone*

Well no. Ou—	Specific capacity [1]	Yield factor [2]	Length of test (hrs)	Average discharge (gpm)	Thickness of aquifer penetrated (ft)	Location	Well diameter (in.)

85	4.0	33	4	8	12	Appleton (4 miles northwest)	6
91	2.9	145	2	20	2	Hortonville (5 miles southeast)	6
201	6.0	9.1	1	30	66	Seymour (1 mile southwest)	5

[1] Gallons per minute per foot of drawdown.

[2] $\frac{\text{Specific capacity} \times 100}{\text{Thickness of aquifer penetrated (feet).}}$

Platteville formation and Galena dolomite.—No attempt was made to differentiate the Platteville formation and the Galena dolomite. The Decorah formation could not be recognized. The unit crops out in many small scarps and is exposed in quarries and stream beds throughout the eastern portion of the county. Many of the older quarries have been abandoned but several large ones are still supplying rock. The Fox River has cut through the overlying glacial drift to the Platteville and Galena unit throughout its reach in Outagamie County, and Duck Creek exposes the formation in several places (pl. 2).

As seen in outcrops, the weathered surface of the rock is usually grayish orange; fresh surfaces range from greenish gray to yellowish gray. Numerous sandy or silty zones weather rapidly, allowing blocks of the more crystalline rock to break off along vertical fractures and slump or fall from the scarps. Other outcrops reveal a series of thin beds with very thin shaly partings between the dolomite layers. In drill cuttings the Platteville and Galena section is recognized by its predominantly gray to bluish-gray color, and there may be as much as 20 feet of fine- to medium-grained gray sandstone (Ou 19) near the base of the unit.

The Platteville and Galena formations contribute water to many domestic and stock wells in the county. At least 2 schools (Ou 279, Ou 285) and 1 industrial plant (Ou 38) rely entirely on this unit for their water supplies. Yields are generally small, and drawdowns are excessive in most of the wells. Some domestic and stock wells that penetrate almost the full thickness of the Platteville and Galena are reported to "pump dry" after a short period of pumping. The presence of recoverable water is evidence that the formation is not an ideal confining bed and that it probably transmits some water to recharge the underlying formations where their head is below that of the Platteville and Galena. Drescher (1953) states that where the Platteville and Galena formations are overlain by the more impervious Maquoketa shale it is of little importance as an aquifer. This indicates that the water moves downward through cracks and solution openings more easily than along the nearly horizontal bedding planes.

Maquoketa shale.—The Maquoketa shale underlies the glacial drift in an area of about 1 square mile in the extreme southeastern corner of Outagamie County. It is a light bluish-gray thin-bedded shale with thin layers of dolomite. In well logs it is described as a blue calcareous or dolomitic shale with some layers of shaly blue or gray dolomite. The shale acts as an effective confining bed for the underlying formations and yields little or no water to wells. It has been reported, however, that well Ou 48 obtains its water entirely from the Maquoketa shale.

CENOZOIC ROCKS

QUATERNARY SYSTEM

Pleistocene deposits.—Glacial deposits of the Wisconsin stage, which cover Outagamie County, consist of lake deposits and glacial drift. The lake deposits are exposed at or near the surface over most of the western two-thirds of the county but are covered by ground moraine of the Valders Substage (Thwaites, 1943) in the eastern part. They consist of layers of silt and clay deposited in deep portions of Lake Oshkosh (Thwaites, 1943), zones of fine-to medium sand deposited in shallow water, and beach sand and gravel laid down around the edge of the lake. The glacial drift in Outagamie County includes both stratified and unstratified deposits. Ground moraine, terminal moraines, and drumlins are composed of unsorted and unstratified material left by the glacier and not reworked by water. Eskers formed by swiftly flowing subglacial streams and consisting of roughly stratified sand and gravel are usually somewhat distorted by slump and covered by unstratified till left by the melting ice sheet. More or less irregular bodies of sorted sand and gravel are found in places within the body of the drift.

Pleistocene deposits are the only water source for wells in the northwest quarter of the county. They furnish adequate supplies to domestic and farm wells and for several public-supply systems. New London is supplied by three wells in drift and alluvium, and the village of Black Creek is supplied by a single well (Ou 71), pumping as much as 170,000 gallons per day from 43 feet of coarse gravel and sand. The specific capacity of the well is 18 gpm per foot of drawdown and the yield factor (p. 9) is 42. In a discussion of Pleistocene deposits the term yield factor has a very limited significance because of the rapid change in character of the water-bearing material. For example, well Ou 169 has a yield factor of only 3.3, yet it penetrates 21 feet of what appears to be the same kind of sand and gravel as that tapped by Ou 71 about half a mile away.

In the southern and eastern parts of the county most of the wells obtain water from the consolidated rocks, and the unconsolidated Pleistocene deposits are cased out to prevent caving. However, many wells obtain sufficient water for domestic and farm use from small, discontinuous sand and gravel lenses, confined in the Pleistocene clay. Because of the discontinuity of the Pleistocene beds, the artesian systems developed locally are small and unrelated, each resulting from recharge on nearby high ground.

Thwaites (1943) has published a detailed study of the Pleistocene geology of part of northeastern Wisconsin. It includes all of Outagamie County except the small portion south of the Fox River.

423220—57——3

Recent deposits.—The Recent deposits consist mostly of silt and very fine sand deposited on the flood plains of the Wolf, Embarrass, and Shioc Rivers. They include also about 55,000 acres of peat (Whitson and others, 1921), which is continually forming in the swamps and marshes. Areas of peat are scattered throughout the county but are most extensive in the western half. The peat deposits in a given swamp are usually thickest near the center, where they sometimes extend to depths of more than 10 feet below the surface.

The thickness of the Recent river deposits in the northwestern quarter of the county is not known. Riverbanks here are low, and flooding of the adjacent lands during high water is quite common. The very fine sand and silt deposited at these times are not important as a source of ground water.

BEDROCK STRUCTURE

The regional bedrock structure is one of gentle dips to the east and southeast (pl. 3). The rocks in Brown County dip at about 30 to 35 feet per mile about S. 70° E. (Drescher, 1953). In eastern Outagamie County the dip, determined from well logs and altitudes, is 25 to 30 feet per mile S. 60° E. The few well logs available for wells in the southwestern quarter of the county indicate that the direction of dip there may be nearly S. 45° E.

Because of the nature of their deposition and subsequent erosion, there is a great range in the thickness of most of the geologic units. The Precambrian floor is an uneven surface that slopes generally 20 to 30 feet per mile toward the east and south. Lying unconformably upon this crystalline floor, the Upper Cambrian series fills in the depressions and covers the areas of low relief, producing a relatively flat inclined plane. The base of the Prairie du Chien group is relatively flat, but its upper surface is described by Chamberlin (1877) as being highly undulating and billowy. The origin of the undulations or domes is uncertain. They have been attributed to Cryptozoön reefs, tectonic deformation, subaerial erosion, and compaction of sediments. The presence of brecciated material within the domes, however, indicates that they were formed after deposition of the original sediments.

The St. Peter sandstone was deposited on the undulating surface of the Prairie du Chien group. It fills in the low areas and generally covers the domes, again producing a relatively even surface. However, where the relief of the Prairie du Chien is unusually great, the sandstone is missing from the high areas and the Platteville and Galena formations rest directly upon the dolomite of the Prairie du Chien group (geologic sections *A–A′* and *D–D′*). This may be the situation in the areas 6 miles west of Freedom and about 6 miles

west of Appleton where the boundaries of the St. Peter sandstone are shown as dashed lines on the geologic map (pl. 2). Field observations in these areas indicate that the formation is absent, and it is not encountered in wells immediately to the east. Except where they have been acted upon by glacial and preglacial erosion, the Platteville and Galena formations have a more uniform thickness than any of the other geologic units. The unit has an even upper surface and rests upon a similar surface formed by the St. Peter sandstone and the Prairie du Chien group.

A west-trending fault along the Wolf River and Bear Creek has been reported by Chamberlin (1877) and others. The only evidence of a fault observed during this investigation is the peculiar right-angle turn in the Wolf River northeast of Hortonville and the straight-line effect caused by Bear Creek coming in from the east. Such a straight-line effect, however, is often the only surface expression of a fault and is sufficient reason for further investigation. The fault is not evident in geologic section D–D′ (pl. 3), which shows only a flattening of the apparent dip probably caused by a change in trend of the line of section (see geologic map, pl. 2). The movement of ground water in the area does not appear to be controlled by a fault (pl. 5), and there is no definite indication of a fault on the bedrock-surface map (pl. 4).

No other major faults or anomalies in structure have been found. The odd bedrock pattern in the vicinity of Seymour (pl. 2) is due not to structure but rather to the preglacial valley that heads in that area.

BEDROCK TOPOGRAPHY

In an area where the glacial drift is an important aquifier, it is necessary to define the buried surface of the consolidated rocks. A map showing contours on the bedrock surface may reveal preglacial valleys and depressions that have no surface expression. These valleys and depressions have been filled with glacial debris which may constitute an additional source of ground water.

The bedrock-contour map (pl. 4) was constructed from data obtained in drillers' logs and from field observations of quarries and other outcrops and surface topography. The altitudes are from aneroid-altimeter traverses using U. S. Coast and Geodetic Survey and U. S. Geological Survey bench marks as control. The lack of sufficient surface and subsurface control, the irregularity of the bedrock surface, and the variable thickness of the drift all tend to limit the accuracy of a map of this type. However, the general character and the dominant features of the buried surface are probably as shown on the map.

The outstanding feature of the preglacial landscape is the large buried valley which may be traced from near Seymour to Shiocton.

It is quite narrow and reaches a depth of 512 feet below the land surface at Black Creek. Although the valley may have been deepened and modified by ice advances, it was probably formed by a pre-Pleistocene stream flowing southwestward and emptying into the ancestral Wolf River at Shiocton. Two smaller valleys to the north also seem to terminate along the course of the present Wolf River, which flows southward to a point about 3 miles northeast of Hortonville where it is joined by a deep, narrow valley from the east. The straight-line effect caused by this confluence has been discussed in the section on bedrock structure. The fact that the present-day streams conform so well to the preglacial drainage pattern is due to the thinness of the drift in much of the county. Although the old channels are buried beneath hundreds of feet of sediments, the streams are still controlled by the same bedrock configurations etched out by their ancestors.

Other prominent features of the old surface are the Mosquito Hills about 1½ miles east of New London. They are preglacial erosional remnants of the Upper Cambrian series which were modified by the advancing ice. A cut-and-fill terrace, which may be an early stream terrace or a wave-cut bench from the time of Lake Oshkosh (Thwaites, 1943), was observed on the west side of the mounds.

The bedrock-topography map used in conjunction with land-surface altitudes shows that the glacial drift is thickest in the buried valleys and in the general area north and west of the Prairie du Chien escarpment. The bedrock surface in the remainder of the county is relatively flat, with no evidence of any great thickness of drift except in drumlins and eskers.

GEOLOGIC HISTORY

The Precambrian rocks that underlie all of Outagamie County were formed during the earliest geologic era. In Wisconsin these rocks consist of igneous rocks, as well as of sedimentary rocks that have been altered by heat and pressure. The Precambrian landscape was rugged and mountainous; even after long periods of exposure to the elements it was still dominated by many hills and ridges.

After the close of the Precambrian the area was covered by a sea into which layer after layer of sediment was deposited. The sea was not stationary, and alternating layers of sandstone, limestone, and shale were deposited as the water advanced and retreated. At times the sea retreated entirely, leaving the deposits exposed to subaerial erosion and continental deposition. From the time of final retreat of the sea until the advent of the Pleistocene glaciers, the rocks were subjected to weathering and erosion. It was during this interval that the bedrock valleys (pl. 4) were cut by the ancestral Wolf River and its tributaries.

Modification of the land surface during Pleistocene glaciation was accomplished more by deposition than by erosion. The valleys were filled, moraines were built up, and new drainage patterns were formed. As the ice front withdrew from its last major advance, much of Outagamie County was again covered by fresh water, of a glacial lake (Thwaites, 1943). Lake sediments were deposited, and then the water withdrew, leaving the land surface much as it appears today. Little erosion has taken place, and deposition has been restricted to flood-plain deposits of silt and sand along the streams and to organic deposits in lakes and swamps.

GROUND WATER

SOURCE AND MOVEMENT

The piezometric surface of a water-bearing formation, or aquifer, may be defined as that surface represented by the water level in wells or other large openings. If the water is not confined by impermeable material, the piezometric surface is called the water table. Under artesian conditions the water is confined under pressure by relatively impermeable material, and the piezometric surface is above the top of the aquifer. Ground water occurs under both artesian and water-table conditions in Outagamie County. Water-table conditions prevail locally in bodies of clean sand or gravel, and in limestone and dolomite where the water moves freely through cracks and solution openings that are connected with the atmosphere. Artesian water occurs locally, confined by layers of silt or clay, in the glacial drift and is the source of many springs and flowing wells. It occurs also throughout the bedrock aquifers wherever it is confined by relatively impermeable dolomite and shale. The confining material is not totally impermeable, and there is much slow leakage through the beds, so that over a long period of time the water may be considered as a single water body rather than several water bodies.

The direction of movement of ground water is illustrated by the piezometric map (pl. 5), which was constructed from water-level measurements made in 91 wells during April 1954. The wells do not represent any one aquifer, as most wells are cased only through the drift, and the leaky-artesian conditions that prevail in much of the county make it impossible to assign a water level to a specific aquifer without a driller's log and casing record of the well. The contour lines represent points of equal altitude on the piezometric surface. Because water flows down the hydraulic gradient, the direction of movement at any given point can be determined. Natural movement is controlled by discharge, recharge, topography, and geologic structure. It is altered by local pumping and by recharge from man-made reservoirs. In the eastern third of Outagamie County the water flows

southeastward. The direction of flow is the result of natural discharge into the Fox River, of recharge from the large area to the west, of municipal and industrial pumping along the Fox River from Lake Winnebago to Green Bay, and of the eastward dip of the bedrock. Industrial and municipal pumping has increased the gradient and hence the volume of water moving toward the areas of discharge, but it has not greatly changed the direction of ground-water movement. An increase in gradient at any given place may also be due to a decrease in permeability of the water-bearing material or to a local increase in recharge.

The quantity of water moving out of the county to the southeast was computed by applying Darcy's law to the area between the 780- and 700-foot contours running northeast from Appleton. From Darcy's law it follows that the quantity of water discharged in a unit of time (Q) is equal to the product of the average permeability of the material (P), the hydraulic gradient (I), and the cross-sectional area through which the water moves (A). It may be written in the form $Q=TIL$, where T is the transmissibility and L is the length of the section perpendicular to the direction of flow. An approximate T of 18,000 gpd per foot was obtained from pumping tests at Seymour and Appleton. L is the average length of the contours between the limiting flow lines A–B and C–D (pl. 5). The gradient, I, is averaged as the quotient of the area between the contours divided by the average length of the contours. Table 4 summarizes the data and results of the computations.

TABLE 4.—*Calculated movement of water to the southeast in Outagamie County, Wis.*

Contour interval (feet)	T (gpd per foot)	I (foot per foot)	L (miles)	Q (mgd)
780–740	18,000	0.0036	29.6	10.1
740–700	18,000	.0040	27.7	10.5

The amount of water moving southeastward is more than 10 mgd. Of this, about 4.5 mgd is pumped from wells along the Fox River from Appleton to Kaukauna. A large quantity is discharged naturally into the river, and the remainder flows downvalley toward the city of Green Bay, where the pumpage is estimated to average about 12.5 mgd.

Throughout the remainder of Outagamie County ground-water movement is controlled mainly by surface and bedrock topography. The water flows outward from the high areas toward lower ground, where it may come to the surface through seeps and springs. The large bedrock valley near Seymour influences ground-water move-

ment in the central part of the county. Water moves toward the valley from both sides and then westward toward the Wolf River. The number and distribution of control wells in the northwestern part of the county did not justify the drawing of piezometric contours in this area. The water here is in glacial drift, and, except in a few places where it is confined by impermeable layers, it exists under water-table conditions. The gradient appears to be quite flat, the water moving toward the Wolf and Embarrass Rivers.

The source of the ground water is precipitation. Recharge to the Paleozoic rocks takes place by percolation through the glacial drift into the subjacent sandstones or dolomites and thence downward into the deeper lying formations. The best opportunities for recharge are in areas where the sandstones crop out or are covered only by permeable glacial deposits. The piezometric map shows that where a stream influences ground-water movement the flow is usually toward the stream, indicating that water is entering rather than leaving the stream.

In areas of local recharge, the seasonal distribution of rainfall and seasonal changes in temperature have a pronounced effect on water levels. Rainfall on a recharge area may add water to the ground-water body; it also reduces the demand for ground water, thus tending to maintain natural conditions. High temperatures create a greater demand for water and a consequent lowering of water levels. High temperatures also increase the rates of evaporation and transpiration, thus reducing the amount of water available for recharge.

WATER LEVELS

Periodic water-level measurements (table 5, figs. 3 and 4) were made in 27 wells during the investigation. In addition, a continuous water-

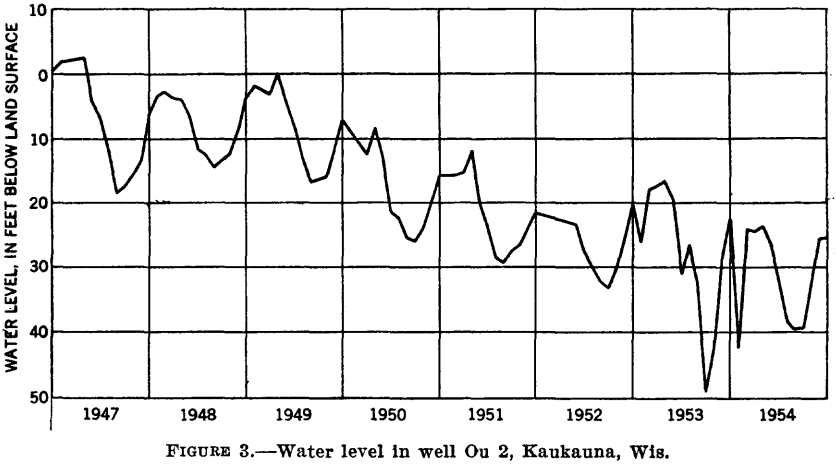

FIGURE 3.—Water level in well Ou 2, Kaukauna, Wis.

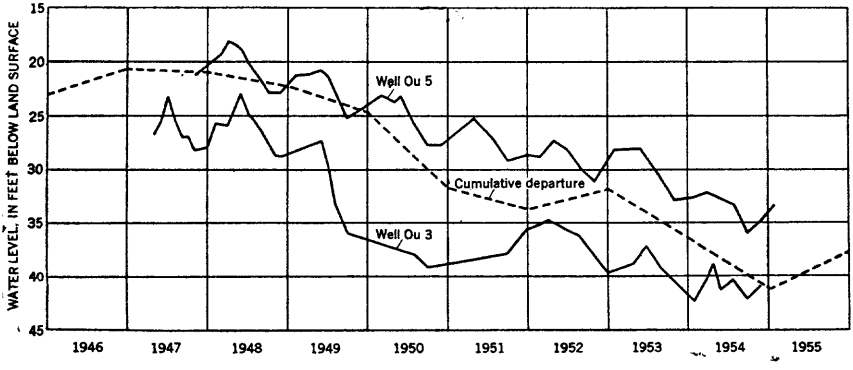

FIGURE 4.—Water levels in two wells and cumulative departure from normal precipitation since 1947–55, Outagamie County, Wis.

level recorder has been in operation on well Ou 2 since December 1946. More than 90 wells were measured in April 1954 for use in construction of the piezometric map (pl. 5).

Fluctuations caused by pumping from a water-table aquifer represent actual removal of water from the aquifer and usually are relatively small. In an artesian aquifer the fluctuations caused by pumping are relatively rapid and large, as they represent mostly changes in pressure within the system. Evaporation of water directly from the ground-water body and evaporation from plants (transpiration) are effective when the ground-water body is at or near the land surface. Barometric and other pressure effects on water levels are most pronounced in wells tapping confined water. Atmospheric pressure is transmitted through the well to the elastic artesian aquifer, and the well acts as a water barometer.

Fluctuations in water level may be grouped into three categories: short-term (ranging from a few seconds or minutes to several days); seasonal; and long-term. Nearly instantaneous fluctuations may be the result of loading of the aquifer by railroad trains, of earthquakes, of pumping from wells, etc. Diurnal or semidiurnal fluctuations may be caused by pumping, diurnal barometric changes, earth tides, or evaporation and transportation. Weekly fluctuations may occur as a result of a decrease in industrial and municipal pumping on weekends.

Seasonal fluctuations are due to seasonal variations in pumping, evaporation and transpiration, and recharge. Normally, water levels decline through the summer as a result of reduced recharge (due to increased evaporation and transpiration) and of drainage into streams. The decline continues through the winter months when the ground is frozen and recharge is at a minimum. Recharge is greatest in the spring, owing to snow melt and spring rains. In southeastern Outagamie County the pattern is distorted by pumping along the Fox River. Hydrographs (figs. 3 and 4) show that the lowest water levels occur in the early fall at the end of the period of heaviest industrial and municipal pumping. Recovery is rapid, and a nearly stable condition is reached early the following year. The water level in well Ou 3, which of the three wells illustrated is that least affected by pumping, follows more closely the natural influences of recharge and discharge. It continues to decline during the winter and reaches its maximum recovery in April or May.

Long-term trends in water levels are the result of precipitation and temperature cycles or of pumping trends. About 8 years of records are available for wells Ou 2, 3, and 5 (figs. 3 and 4). All three

wells are affected by increased pumping at Green Bay and along the Fox River, and all three hydrographs show a downward trend during the period of record. However, the cumulative-departure curve for precipitation in Outagamie County also shows a downward trend during this period. The curve follows quite closely the trend of the hydrographs, indicating that the precipitation cycle has a definite influence on water levels. The effects of precipitation and temperature cycles on water levels are accentuated by corresponding pumping cycles; for example, high temperatures and lack of precipitation, which reduce recharge and cause water levels to decline, usually result in increased pumping, which has a similar effect. Wells Ou 2 and 5 are deep wells near the area of maximum withdrawal and relatively far from the recharge area. Here the effect of pumping is at a maximum and the effect of fluctuations in precipitation are minimized. Well Ou 3 is a shallow well located near the outcrop area, where water levels are influenced by precipitation cycles. This influence is shown by the trend of the hydrograph, which follows very closely the cumulative-departure curve for precipitation. The well is west of the recharge boundary, determined by Drescher (1953), for the Green Bay area and should not be greatly affected by withdrawals at Green Bay.

USE

Withdrawal of ground water in Outagamie County in 1951 and 1952 is estimated to have averaged about 9.0 mgd. Industrial, commercial, and public-supply pumping along the Fox River accounts for 48 percent of the total. The city of Appleton and the paper mills use Fox River water, but pumping by other industries and businesses in the Appleton area amounts to about 1.7 mgd. The cities of Kaukauna, Little Chute, Kimberly, and Combined Locks use ground water at the rate of 2.6 mgd for all purposes. Pumpage in the remainder of the county, estimated to be about 4.6 mgd, is predominantly for domestic and general farm use. The estimate is based on pumpage figures supplied by the villages and on an estimated average consumption of 40 gallons per day (gpd) per person for rural areas, 35 gpd per cow for milk cows and associated dairy servicing, 12 gpd for cattle and horses, and smaller amounts for other animals.

WELLS

The locations of the 287 wells visited during the investigation are shown on plate 1. The data assembled for each well are listed in table 6. Wells are numbered consecutively in the order visited and prefixed by the letters Ou to show that they are in Outagamie County.

Drilled wells range in diameter from 3 to 16 inches, depending upon the size and type of pump to be used and the yield required. Those ending in consolidated rock are usually cased only through the drift; those penetrating just the drift use perforated casing or screen to keep the hole open and to allow water to enter the well. Some wells ending in coarse sand or gravel are cased with unperforated pipe, and water enters through the open bottom of the casing.

When a relatively small quantity of water is needed for stock or domestic use, a well may be driven into sandy deposits of the glacial drift or lake sediments. Such wells are usually 1¼ to 2½ inches in diameter and have a well point or a length of slotted pipe near the bottom. The driven well is best suited to the sandy areas in the northwestern quarter of the county.

A few dug wells are still in use for domestic and stock supplies, but most of them have been replaced by drilled or driven wells. The dug wells are 3 to 5 feet in diameter and as much as 30 feet deep. They have been dug by hand or by power shovel and are lined with stone to prevent caving. The material penetrated must be firm and must stand without caving, so the wells are usually dug through clay to the top of a more permeable underlying bed.

Twenty-four of the wells visited exceed 500 feet in depth. Of these, 20 are industrial or municipal wells along the Fox River. The deepest well visited is Ou 35, drilled for the Village of Kimberly and ending in granite at 804 feet. The average depth of the 257 wells whose depth is known is 195 feet, the median depth of the same wells is 127 feet—that is, 128 wells are less than and 128 wells are more than 127 feet deep.

SPRINGS

A spring is the discharge of ground water, under hydrostatic pressure, at the land surface or into lakes and streams. There are many different types of springs, but the two most common in Outagamie County may be classed as seepage and contact springs. Seepage springs represent an outcrop of the water table and may disappear during periods of water-table decline. They are most numerous in the low, marshy areas along the Wolf and Embarrass Rivers, where there is a considerable amount of effluent seepage. Although most marshy areas are the result of effluent ground-water seepage, in most places the seepage is not concentrated enough to be classed as a spring.

Contact springs occur when the contact between a permeable and an impermeable formation is exposed at the surface. Along the Fox River, ground water percolates downward through the glacial drift to the top of the less permeable Platteville formation, where some of the water moves laterally toward the river and issues as springs along the sides of the valley. At the base of the escarpment of Prairie du

Chien rocks between Hortonville and New London the process is reversed. Here artesian water rising in the permeable sandstone of Cambrian age is partly retarded by the overlying dolomite of the Prairie du Chien group and flows to the surface along the contact near the base of the scarp.

Weidman and Schultz report that springs were a common source of water supply in the county at the time of their report (1915), but now few are in use.

PUMPING TESTS

Determination of the hydraulic characteristics of an aquifer is essential in predicting the effects of withdrawal of water from it. The term coefficient of transmissibility is used to designate the amount of water, in gallons, that will pass in 1 day across a vertical strip of the aquifer, 1 foot wide and extending the full thickness of the aquifer, under a unit hydraulic gradient. The coefficient of storage of an aquifer is the volume of water it releases from or takes into storage per unit surface area of the aquifer per unit change in the component of head normal to that surface.

The most reliable short-term method of determining the hydraulic characteristics of an aquifer is to apply the nonequilibrium formula of Theis (1935) to observations of the amount and rate of change in the piezometric surface at or near a discharging well.

The nonequilibrium formula is:

$$s = \frac{114.6\,Q}{T}\,W(u)$$

where $$W(u) = \int_u^\infty \frac{e^{-u}du}{u} = -0.577216 - \log_e u + u - \frac{u^2}{2\cdot 2!} + \frac{u^3}{3\cdot 3!} - \frac{u^4}{4\cdot 4!} \cdots$$

and $$u = \frac{1.87r^2S}{Tt}$$

where s = drawdown, in feet, at observation well
Q = discharge, in gallons per minute
T = coefficient of transmissibility, in gpd/ft
r = distance, in feet, from observation well to pumped well
S = coefficient of storage
t = time, in days, since pumping started

To develop the formula it was assumed that the aquifer is infinite in extent and confined between impermeable beds, that it transmits water equally in all directions and releases water from storage instantaneously with a decline in artesian head, and that its hydraulic characteristics do not change. It is recognized that these are ideal conditions which are never completely satisfied in nature, but in many areas they are substantially satisfied.

SEYMOUR TESTS

The pumping tests at Seymour in April 1949 consisted of pumping wells that tap sandstone of Cambrian age and observing the effects produced on the piezometric surface. Water-level measurements were

made with a steel tape in wells Ou 10 and 11 and with an air line in well Ou 1. Well Ou 7 was equipped with a water-stage recorder which made a continuous record of the water level in the well. The hydrographs (pl. 6) show the decline and recovery of water levels in three observation wells and the drawdown and recovery in the pumped well. Distances between wells are given in table 7, and computed values of the coefficients of transmissibility and storage are listed in table 8.

TABLE 7.—*Distances, in feet, between pumped well and observation wells used during pumping tests at Seymour, Wis.*

[a] Not figured in average because well is shallow and penetrates a zone separated from principal aquifer by a shaly horizon.

Wells Ou 1 and 10 are deep wells which penetrate more than 200 feet of the sandstone. Well Ou 7 is drilled about 15 feet into the sandstone, and well Ou 11 is a shallow well which may be separated from the sandstone by several feet of shale. The shallow penetration of wells Ou 7 and 11 is reflected in their hydrographs, which show a relatively narrow range of fluctuations during the tests. For example, the water level in well Ou 11 was lowered less than 8 feet when well Ou 1 was pumped, whereas the water level in well Ou 10, at a much greater distance from the pumping well, was lowered nearly 6 feet during the same period. The small irregularities in the hydrograph of well Ou 7 were caused by the pumping of a shallow well nearby.

APPLETON TEST

In March 1954 a test was made in Appleton, using well Ou 22 as the pumped well and well Ou 253 as an observation well. The wells are 1,115 feet apart and both are open in the St. Peter sandstone, the dolomite of the Prairie du Chien group, and the underlying sandstone of Cambrian age. The average coefficient of transmissibility obtained from the drawdown and recovery tests is about 19,000 gpd per foot. The average coefficient of storage for the two tests is about 0.00015. The coefficients are based on measurements in only one observation well and may not be representative. However, they are in close agreement with values obtained in the Seymour tests, and the specific capacities of the wells are similar to those of other wells in the Appleton area.

HORTONVILLE TESTS

In Hortonville, pumping tests were made in October 1953 using wells Ou 33 and 80 as pumped wells and Ou 81 and 248–252 as observation wells. The pumped wells tap sandstone of Cambrian age which lies immediately below the glacial drift in this area.

Values obtained for the coefficient of transmissibility (T) range from about 27,000 to about 75,000 gpd per foot and average about 43,000 gpd. Values of the coefficient of storage (S) range from about 0.00006 to about 0.0009 and average about 0.0004. The wide range in T and S values, which is attributed to local recharge and the fact that some of the observation wells may terminate in the glacial drift, make it impossible to apply the values to a prediction of interference or water-level trends.

QUALITY

Chemical analyses of 37 samples of ground water from Outagamie County are listed in table 9. The chemical quality of the water differs greatly from well to well. For example, the mean hardness is about 385 ppm (median 300 ppm), but the range in hardness is from 1,200 ppm to 58 ppm. Although the water generally is very hard, the dissolved-solids content averages about 540 ppm (median about 350 ppm); a limit of 500 ppm is recommended by the U. S. Public Health Service (1946) for drinking and culinary water. The sulfate concentration ranges from 815 ppm to less than 1 ppm and averages about 169 ppm (median 30 ppm). The limit suggested by the Public Health Service for sulfate is 250 ppm. High iron content is a problem in many wells. A concentration of 27 ppm is reported in well Ou 56. However, in 34 analyses listed in table 9 the range is from 4.0 ppm to 0.0 ppm and the average is about 0.8 ppm (median 0.4 ppm). The median is 0.1 ppm above the limit set by the Public Health Service for iron, or iron and manganese together.

[a] Weidman, Samuel, and Schultz, A. R., 1915, p. 493.

Information on the chemical character of ground water is important to all users of this valuable resource. It is also an important tool for use by the hydrologist interested in the source and movement of water. A table of analyses, such as table 9, presents the available data but the form is not readily adaptable for interpretive work. In the past, several illustrative methods have been used to show the similarity or dissimilarity of various waters. These methods include the bar graph, the pie diagram, the trilinear plot, and others, each of which has advantages and disadvantages. R. C. Vorhis of the U. S. Geological Survey has suggested for interpretive work the use of a logarithmic diagram (Schoeller, 1935) adopted by the French hydrogeologists in Tunisia, Algeria, and French Morocco. The diagram consists of vertical logarithmic scales for constituents and properties, and the graph is a series of straight-line segments connecting the values plotted for each analysis (pl. 7). The similarity or difference of two analyses is readily apparent from a comparison of their graphs.

Logarithmic graphs for 22 analyses are shown on plate 7. They are grouped by geologic source to show that the source is the predominant factor in determining the pattern of the graph. The form of the graphs in diagram *A* is distinctive and is characteristic for wells that tap all the Paleozoic formations below the Maquoketa shale. Water from the Maquoketa shale is similar to, but more highly mineralized than, water from the Platteville and Galena formations (diagram *B*). Water from rocks of the Upper Cambrian series (diagram *C*) is generally characterized by a low chloride and sulfate content. Well Ou 10, which does not fit this pattern, is an old well cased through the Prairie du Chien. However, the graph for Ou 10 closely resembles those of diagram *D*, indicating that water from the Prairie du Chien must be entering the well through a defective casing, raising the sulfate content of the water sampled. The patterns of diagrams *D* and *E* are noticeably alike. They represent water from similar material but of a different age.

The graphs for well Ou 114 (diagram *C*), Ou 196 (diagram *D*), and Ou 85 (diagram *E*) are anomalous because of an abnormally high chloride content. This is attributed to their location near poorly drained, marshy areas where the chloride concentration of the water is increased by surface evaporation of the stagnant water. The pattern of diagram *F*, representing water from Pleistocene deposits, is somewhat similar to that of diagrams *D* and *E*, except for the nearly straight line formed by the calcium-magnesium-hardness plot.

The logarithmic diagram has been useful in the study of the geology and ground water of Outagamie County. Although a limited number of analyses were made and plotted, a definite tendency toward characteristic patterns for the various sources of water was

evident. Where other evidence was inconclusive, comparisons of water-analysis graphs helped in determining the source and movement of water and in establishing geologic boundaries.

CONCLUSIONS

More than three-fourths of Outagamie County is underlain by thick beds of sandstone of Cambrian age which supply most of the water to industrial and public-supply wells along the Fox River. Consolidated rocks of the St. Peter sandstone, Platteville formation and Galena dolonite, and Prairie du Chien group and unconsolidated deposits of Pleistocene age are tapped by many domestic and farm wells and probably could be developed to a much greater extent. An especially promising reservoir is the buried preglacial valley that heads near Seymour.

Recharge occurs throughout most of the county but is greatest in areas where the sandstones are at or near the surface. Practically all recharge is from local precipitation. Ground-water discharge occurs naturally by flow from contact and seepage springs; by diffused seepage into swamps, from which it is evaporated and transpired, and into streams; and by underflow to the south and east.

Ground-water pumpage along the Fox River in Outagamie County was about 4.3 mgd in 1952. There is no evidence of overdraft at present, but additional pumping tests should be made to determine the acquifer characteristics in localities other than the few already tested, to enable prediction of water-level trends and interference that would result from additional development.

WELL LOGS

Tables 10 and 11 contain selected logs of wells drilled in Outagamie County. The descriptions and stratigraphic correlations in table 10 are by F. T. Thwaites of the Wisconsin Geological Survey from his examination of drill cuttings from each well. In table 11, descriptions of the material penetrated are those of the driller and stratigraphic correlations are by the author.

Logs of 337 wells were collected from several sources during the investigation. Of these, 161 were located in the field, 49 logs were used in construction of the geologic sections, and 45 logs are published in tables 10 and 11. Essentially all drilling in the county is by the cable-tool method. This method, when used by experienced drillers facilities accurate logging of wells.

Sandstone, very fine grained, pink, dolomitic; dolomite, gray	14	359
Sandstone, fine-grained, light-gray, dolomitic	10	369
Sandstone, medium- to very fine grained, pink, dolomitic	5	374
Sandstone, fine-grained, dark pink, dolomitic, glauconitic	8	382
Sandstone, fine-grained, dark-gray, dolomitic, glauconitic	5	387
Sandstone, fine-grained, silty, green, dolomitic	27	414
Sandstone, medium- to fine-grained, gray, white	7	421
Sandstone, very fine to fine-graine , dark-gray, dolomitic	29	450
Sandstone, fine-grained, gray, dolomitic	15	465
Sandstone, fine- to medium-grained, gray, dolomitic	20	485
Sandstone, medium- to fine-grained, gray, silty	5	490
Sandstone, fine- to medium-grained, silty, light-gray	15	505
Sandstone, medium- to fine-grained, silty, gray	25	530
Sandstone, fine- to medium-grained, light-gray	10	540
Sandstone, very fine to fine-grained, light-gray	15	555
Sandstone, fine- to medium-grained, light-gray	65	620
Sandstone, medium- to fine-grained, light-gray	10	630
Sandstone, fine- to medium-grained, light-gray	20	650
Sandstone, medium- to fine-grained, light-pink-gray	10	660
Sandstone, fine-grained, silty, pink	15	675
Sandstone, fine-grained, light-gray	20	695
Sandstone, medium- to fine-grained, light-gray	30	725
Sandstone, fine- to medium-grained, light-gray	5	730
Precambrian:		
Granite, light-pink	4	734

Well Ou 71, SE¼SW¼ sec. 9, T. 23 N., R. 17 E.

Glacial drift:		
Clay, red, dolomitic	80	80
Clay, gray, dolomitic	35	115
Gravel, coarse, pebbles to over ½-inch, stony	40	155
Sand, coarse, gray	3	158

Well Ou 82, SE¼NE¼ sec. 2, T. 21 N., R. 15 E.

Glacial drift:		
Till, red, dolomitic	8	8
Till, light pinkish-gray, dolomitic	72	80
Upper Cambrian series:		
Dolomite, very sandy, pink, red; shale, red	14	94
Sandstone, medium-grained, light-gray, pink, dolomitic, glauconitic	6	100
Sandstone, medium-grained, white	20	120
Sandstone, medium-grained, white; some yellow gray, dolomitic	14	134

Well Ou 97, SE¼SE¼ sec. 8, T. 23 N., R. 17 E.

Glacial drift:		
Surface soil	2	2
Clay, red	50	52
"Pack sand" and "quicksand"	38	90
"Sand-pan" and "quicksand"	20	110
"Gumbo" clay, red	20	130
"Gumbo" clay, black	38	168
"Hardpan"	100	268
"Pack sand"	2	270
Sand, coarse	8	278
"Hardpan"	25	303
"Hardpan" and "bedrock"	28	331
Sand	2	333
"Bedrock"	12	345
Sand, coarse; some water: "pack sand"	5	350
Gravel, very coarse; "hardpan"	5	355
Sand, very coarse; some water	10	365
"Hardpan," blue and gray	5	370
Gravel, coarse, and "hardpan," gray	10	380
"Bedrock" and gravel	5	385
Sand, rock and gravel; layers of mud	10	395
Gravel and rock, streaks of clay, dry, red; gravel and sand	23	418
Gravel and sand, clay, dry, red and streaks of shale rock mixed	28	446
Rock	3	449
"Shale hardpan"	24	473
Streaks of rock and shale	11	484
No record	28	512
Precambrian:		
Granite, pink, gneissic	58	570

TABLE 10.—*Materials penetrated by wells in Outagamie County, Wis.*—Continued

Well Ou 101, SE¼NE¼ sec. 31, T. 23 N., R. 17 E.

	Thickness (feet)	Depth (feet)
Glacial drift:		
Gravel and sand	8½	8½
Prairie du Chien group:		
Dolomite, gray	5½	14
Dolomite, brownish-gray, sandy, pyritic	5	19
Dolomite, gray	31	50
Dolomite, pink and gray	30	80
Dolomite, gray, green, and pink; chert, white, oolitic	11	91
Upper Cambrian series:		
Sandstone, medium-grained, gray, dolomitic	8	99
Sandstone, very fine grained, pink, red and gray, dolomitic	19	118
Sandstone, very fine grained, red and gray, very dolomitic, hard	6	124
Dolomite, sandy, red, glauconitic	6	130
Sandstone, very fine grained, dark red, dolomitic, glauconitic	5	135
Sandstone, medium-grained, gray and pink, dolomitic	75	210
Sandstone, very fine grained, gray, dolomitic, some glauconite	5	215
Sandstone, medium-fine-grained, white, dolomitic, glauconitic	15	230
Sandstone, medium-to fine-grained, light-gray, dolomitic, hard	10	240
Sandstone, like above with streaks of gray dolomite	10	250
Sandstone, medium-to-fine-grained, white	25	275
Sandstone, medium-to-fine-grained, white, streaks of pink dolomite	20	295
Sandstone, fine-to-coarse-grained, white	10	305

Well Ou 102, NW¼SW¼ sec. 23, T. 21 N., R. 18 E.

Glacial drift:		
Till, red, dolomitic	10	10
Clay, gray, dolomitic	10	20
Till, gray, dolomitic	5	25
Galena dolomite and Platteville formation:		
Dolomite, gray	30	55
Dolomite, light-gray	30	85
Dolomite, light-gray and gray	20	105
Dolomite, blue-gray	20	125
No samples	20	145
Dolomite, light-gray	10	155
Dolomite, gray and light-gray	40	195
Dolomite, light-gray; much sand	20	215
Prairie du Chien group:		
Dolomite, light-gray, green spots	20	235
Dolomite, light-gray	10	245
Dolomite, light-gray; chert, dense and oolitic, red and gray; sandstone, fine-grained, white, very dolomitic	40	285
Dolomite, light-gray	17	302

Well Ou 280, NW¼NW¼ sec. 34, T. 21 N., R. 17 E.

Glacial drift:		
Sand, fine, gray-pink, weathered	5	5
Till, pink, dolomitic	80	85
Gravel, fine, stony	5	90
Till, light yellow-gray	5	95
Galena dolomite and Platteville formation:		
Dolomite, light-gray; some light blue-gray	10	105
Sandstone, medium-to fine-grained, light-gray, dolomitic	10	115
St. Peter sandstone:		
Sandstone, fine-to medium-grained, very light gray	20	135
Chert, gray, pink-gray	5	140
Shale, red; chert, green-gray, pink	5	145
Chert, gray, yellow-gray, pink-gray; quartzite, fine-grained, light-gray	40	185
Prairie du Chien group:		
Dolomite, very light gray	30	215
Dolomite, light-gray to very light gray	20	235
Dolomite, light-gray	40	275
Dolomite, light-gray, pink, some sand	5	280
Dolomite, very light gray, light-gray	30	310
Dolomite, very light gray, sandy; chert, gray, oolitic	5	315
Upper Cambrian series:		
Sandstone, very fine-grained, very light gray, dolomitic	10	325
Sandstone, very fine grained to silty, orange-pink, dolomitic	5	330
Siltstone, red-brown, red, red-orange, green-gray, glauconitic, dolomitic; shale, gray-green	25	355
Sandstone, fine-grained, pale-red, dolomitic, glauconitic	5	360
Sandstone, fine-grained, light pink-gray, dolomitic, glauconitic	10	370
Sandstone, fine- to medium-grained, light-gray, dolomitic, some glauconite	65	435
Sandstone, fine-grained, light-gray, some glauconite	15	450
Siltstone, light medium-grained, gray, dolomitic, hard	5	455
Sandstone, fine- to coarse-grained, light-gray, dolomitic	10	465

TABLE 10.—*Materials penetrated by wells in Outagamie County, Wis.*—Continued

Well Ou 280, NW¼NW¼ sec. 34, T. 21 N., R. 17 E.—Continued

	Thickness (feet)	Depth (feet)
Upper Cambrian series—Continued		
Sandstone, fine- to medium-grained, very light gray	45	510
Sandstone, medium- to fine-grained, very light gray	5	515
Sandstone, fine- to medium-grained, very light gray	110	625
Sandstone, medium- to fine-grained, very light gray	5	630
Sandstone, fine- to medium-grained, very light gray	25	655
Sandstone, medium- to fine-grained, very light gray	5	660
Sandstone, very fine to medium-grained, very light gray	20	680
Sandstone, fine- to medium-grained, very light gray	10	690
Sandstone, very fine to medium-grained, very light gray	10	700
Sandstone, medium- to fine-grained, very light gray	5	705
Sandstone, fine- to medium-grained, very light gray	10	715
Sandstone, medium- to fine-grained, very light gray	5	720
Sandstone, fine- to medium-grained, very light gray	25	745

TABLE 11.—*Materials penetrated by wells in Outagamie County, Wis.*

Interpretation, by the author, of drillers' logs from the files of the Wisconsin State Board of Health]

Well Ou 104, NW¼SE¼ sec. 32, T. 21 N., R. 17 E.

	Thickness (feet)	Depth (feet)
Alluvium and drift:		
Clay	10	10
Gravel	23½	33½
Galena dolomite and Platteville formation:		
Lime rock	8½	42
St. Peter sandstone:		
Sandstone	7	49

Well Ou 105, NE¼SW¼ sec. 29, T. 21 N., R. 16 E.

Alluvium and drift:		
Gravel and sand	30	30
Sand and clay	12	42
Prairie du Chien group:		
Limestone	86	128
Upper Cambrian series:		
Sandstone	14	142

Well Ou 106, NW¼SW¼ sec. 36, T. 21 N., R. 15 E.

Alluvium and drift:		
Sand and gravel	40	40
Prairie du Chien group:		
Limestone	86	126
Upper Cambrian series:		
Sandstone	12	138

Well Ou 107, NW¼NW¼ sec. 33, T. 22 N., R. 16 E.

Alluvium and drift:		
Clay	10	10
Clay and sand	40	50
Sand	10	60
Hardpan	5	65
Prairie du Chien group:		
Limestone	100	165
Upper Cambrian series:		
Sandstone, red	15	180

Well Ou 111, NE¼NE¼ sec. 32, T. 22 N., R. 18 E.

Alluvium and drift:		
Clay	34	34
Galena dolomite, Platteville formation, and Prairie du Chien group:		
Limestone	206	240
Sandstone	10	250
Limestone	55	305

TABLE 11.—*Materials penetrated by wells in Outagamie County, Wis.*—Continued

Well Ou 115, SW¼SW¼ sec. 30, T. 22 N., R. 18 E.

	Thickness (feet)	Depth (feet)
Alluvium and drift:		
Clay	15	15
Sand and gravel	45	60
Hardpan and stones	30	90
Galena dolomite, Platteville formation, and Prairie du Chien group:		
Shell limestone	6	96
Limestone	208	304

Well Ou 117, SE¼SE¼ sec. 6, T. 22 N., R. 18 E.

Alluvium and drift:		
Clay	40	40
Sand	17	57
Hardpan	16	73
Galena dolomite and Platteville formation:		
Hard rock	23	96
St. Peter sandstone:		
Sandstone	34	130

Well Ou 119, SE¼SE¼ sec. 18, T. 24 N., R. 17 E.

Alluvium and drift:		
Soil and clay	28	28
Quicksand	40	68
Clay	49	117
Hardpan	20	137
Gravel		

Well Ou 124, SE¼NE¼ sec. 30, T. 23 N., R. 19 E.

Alluvium and drift:		
Sand	20	20
Clay	6	26
Hardpan	16	42
Clay	16	58
Galena dolomite and Platteville formation:		
Limestone	42	100
St. Peter sandstone:		
Shale	2	102
Limestone	1	103
Shale	4	107
Sandstone	13	120

Well Ou 126, NW¼SW¼ sec. 20, T. 23 N., R. 19 E.

Alluvium and drift:		
Sand	46	46
Clay	11	67
Hardpan	11	78
Clay	12	90
Gravel	2	92

Well Ou 152, SE¼SW¼ sec. 12, T. 23 N., R. 17 E.

Alluvium and drift:		
Clay	42	42
Hardpan	4	46
Clay	10	56
Hardpan	29½	85½

Well Ou 154, SE¼NW¼ sec. 30, T. 24 N., R. 17 E.

Alluvium and drift:		
Soil and sand	6	6
Clay	20	26
Quicksand	15	51
Clay	53	103
Hardpan	10	113
Sand and gravel		

TABLE 11.—*Materials penetrated by wells in Outagamie County, Wis.*—Continued

Well Ou 163, SW¼SW¼ sec. 6, T. 23 N., R. 18 E.

	Thickness (feet)	Depth (feet)
Alluvium and drift:		
Sand	10	10
St. Peter sandstone:		
Sandstone	44	54

Well Ou 167, SE¼SE¼ sec. 5, T. 22 N., R. 17 E.

Alluvium and drift:		
Soil and clay, red	50	50
Hardpan and gravel	23	73
Prairie du Chien group:		
Limestone	52	125
Upper Cambrian series:		
Sandstone	100	225

Well Ou 175, NW¼NE¼ sec. 5, T. 24 N., R. 17 E.

Alluvium and drift:		
Sand	15	15
Clay	25	40
Quicksand	30	70
Clay	60	130
Hardpan	11	141
Sand, coarse	10	151

Well Ou 177, NW¼NE¼ sec. 9, T. 24 N., R. 16 E.

Alluvium and drift:		
Overburden	68	68
Upper Cambrian series:		
Sandstone	34	102

Well Ou 188, SE¼SW¼ sec. 24, T. 24 N., R. 16 E.

Alluvium and drift:		
Soil, sandy	12	12
Clay, hard	65	77
Hardpan	26	103
Sand		

Well Ou 193, SW¼NW¼ sec. 15, T. 23 N., R. 17 E.

Alluvium and drift:		
Clay	80	80
Sand	20	100
Hardpan	50	150
Gravel	4	154

Well Ou 197, NW¼NW¼ sec. 35, T. 23 N., R. 16 E.

Alluvium and drift:		
Soil	40	40
Hardpan	48	88
Upper Cambrian series:		
Sandstone	12	100

Well Ou 200, NW¼NW¼ sec. 26, T. 21 N., R. 15 E.

Alluvium and drift:		
Soil and clay	7	7
Prairie du Chien group:		
Shell rock	6	13
Limestone	42	55
Upper Cambrian series:		
Sandstone	11	66

TABLE 11.—*Materials penetrated by wells in Outagamie County, Wis.*—Continued

Well Ou 206, NE¼NE¼ sec. 32, T. 23 N., R. 18 E.

	Thickness (feet)	Depth (feet)
Alluvium and drift:		
Soil	13	13
Galena dolomite and Platteville formation:		
Limestone	27	40

Well Ou 227, NW¼NW¼ sec. 30, T. 24 N., R. 15 E.

Alluvium and drift:		
Clay	22	22
Sand and clay	68	90
Sand, fine	11	101
Sand, medium	5	106

Well Ou 230, SW¼SW¼ sec. 28, T. 24 N., R. 15 E.

Alluvium and drift:		
Soil and clay, red	25	25
Quicksand	10	35
Clay, blue and stones	40	75
Sand	3	78
Clay, red; sand, stones	50	128
Clay, blue	23	151
Gravel	8	159

Well Ou 232, NW¼SW¼ sec. 7, T. 23 N., R. 15 E.

Alluvium and drift:		
Sand	25	25
Clay	55	80
Sand and gravel	20	100

Well Ou 235, NW¼SW¼ sec. 19, T. 22 N., R. 15 E.

Alluvium and drift:		
Sand	106	106
Clay	67	173
No record	7	180
Sand	9	189
Gravel	8	197

Well Ou 263, SW¼NW¼ sec. 24, T. 22 N., R. 16 E.

Alluvium and drift:		
Clay	10	10
Sand and clay	20	30
Sand	60	90
Hardpan	20	110
Sand	62	172
Rock	8	180
Upper Cambrian series: Sandstone	162	342

Well Ou 272, SE¼NW¼ sec. 17, T. 22 N., R. 16 E.

Alluvium and drift:		
Clay and stones	43	43
Sand	22	65
Upper Cambrian series:		
Sand rock	60	125

Well Ou 275, SW¼SW¼ sec. 8, T. 22 N., R. 16 E.

Alluvium and drift:		
Clay, sand, gravel, and hardpan	205	205
Rock (could not drill farther)		205

TABLE 11.—*Materials penetrated by wells in Outagamie County, Wis.*—Continued

	Thickness (feet)	Depth (feet)
Well Ou 279, NW¼NW¼ sec. 1, T. 24 N., R. 18 E.		
Alluvium and drift:		
Clay	16	16
Hardpan	14	30
Clay	8	38
Galena dolomite and Platteville formation:		
Limestone	25	63
Well Ou 283, SW¼NW¼ sec. 24, T. 22 N., R. 17 E.		
Alluvium and drift:		
Clay	35	35
Sand	60	95
Clay	28	123
Sand	60	183
Hardpan	5	188
Galena dolomite, Platteville formation, and Prairie du Chien group:		
Lime rock	70	258
Upper Cambrian series:		
Sandstone	97	355
Well Ou 285, NE¼NW¼ sec. 7, T. 21 N., R. 17 E.		
Alluvium and drift:		
Soil	5	5
Clay	25	30
Hardpan	12	42
Galena dolomite and Platteville formation:		
Limestone, hard	88	130
Limestone, porous	24	154

Pre-CERCLA Screening Checklist/Decision Form

This form is used in conjunction with a site map and any additional information required by the EPA Region to document completion of a Pre-CERCLA Screening (PCS). The form includes a decision on whether a site should be added to the Superfund program's active site inventory for further investigation. This checklist replaces Attachment A in the December 2016 PCS Guidance document. A current version of the PCS checklist and additional information is available at: https://www.epa.gov/superfund/pre-cercla-screening.

Site Description

Use this section to briefly describe site background and conditions if known or (easily) available, such as: operational history; physical setting and land use; site surface description, soils, geology and hydrogeology; source and waste characteristics; hazardous substances/contaminants of concern; historical releases, previous investigations and cleanup activities; previous regulatory actions, including permitting and enforcement actions; institutional controls; and community interest.

Parcel J is a strip of river bank no more than 46 feet wide, immediately upstream (west) of the Kaukauna City Dam and Power Canal, on the south side of the river. The property has more than a century of activity, dating back to 1885 with the Kaukauna Water Power Company, and likely before. As of 1910, a railroad spur and associated buildings existed on and adjacent to the property. The USACE took over supervision of river traffic in the late 1800s, and the property transferred to federal ownership in the early 1900s.

Photographs from the 1950s show a mostly wooded lot and existence of a small pond. Also according to aerial photographs, filling activities took place beginning in the 1960s, and an unimproved road existed until at least 1992. Since approximately 2000, residential apartment complexes neighbor the riverbank. The riverbank exists as partially-wooded grass yard as of 2019.

Geospatial Information

Latitude: +44.281215 **Longitude:** -88.276265

Decimal Degree North (e.g., 38.859156) Decimal Degree West (e.g., 77.036783)

Provide 4 significant digits at a minimum, more if your collection method generates them.

Except for certain territories in the Pacific Ocean, all sites in U.S. states and territories are located within the northern and western hemispheres and will have a positive latitude sign and negative longitude sign. Coordinate signs displayed above are based on the State/Territory entry on page A-1. Geospatial data tips from the PCS Guidance document are available **here**.

Point Description: Select the option below that best represents the site point for future reference and to distinguish it from any nearby sites. See additional information **here**.

- ☐ Geocoded (address-matched) Site Address
- ☐ Site Entrance (approximate center of curb-cut)
- ☒ Approximate Center of Site
- ☐ Other Distinguishing Site Feature (briefly describe):

Point Collection Method: Check the method used to collect the coordinates above and enter the date of collection. See additional information **here**.

- ☒ Online Map Interpolation
- ☐ GPS (handheld, smartphone, other device or technology with accuracy range < 25 meters)
- ☐ GPS Other (accuracy range is ≥ 25 meters or unspecified)
- ☐ Address Matching: Urban
- ☐ Address Matching: Rural
- ☐ Other Method (briefly describe below):

Collection Date (mm/dd/yyyy): 04/15/2019

POINT-SELECTION CONSIDERATIONS

- Often the best point is a feature associated with the environmental release or that identifies the site visually.
- Use the curb cut of the entrance to the site if there is a clear primary entrance and it is a good identifier for the overall location.
- The approximate center of the site (a guess at the centroid) is useful for large-area sites or where there are no appropriate distinguishing features.
- Use the geocoded address if that is the only or best option available, but if possible use something more representative for sites larger than 50 acres.

Complete this checklist to help determine if a site should be added to the Superfund Active site inventory. See Section 3.6 of the PCS guidance for additional information.	YES	NO	Unknown
1. An initial search for the site in EPA's Superfund active, archive and non-site inventories should be performed prior to starting a PCS. Is this a new site that does not already exist in these site inventories?	☒	☐	☐
2. Is there evidence of an actual release or a potential to release?	☒	☐	☐
3. Are there possible targets that could be impacted by a release of contamination at the site?	☒	☐	☐
4. Is there documentation indicating that a target has been exposed to a hazardous substance released from the site?	☒	☐	☐
5. Is the release of a naturally occurring substance in its unaltered form, or is it altered solely through naturally occurring processes or phenomena, from a location where it is naturally found?	☒	☐	☐
6. Is the release from products which are part of the structure of, and result in exposure within, residential buildings or business or community structures?	☐	☒	☐
7. If there has been a release into a public or private drinking water supply, is it due to deterioration of the system through ordinary use?	☐	☒	☐
8. Are the hazardous substances possibly released at the site, or is the release itself, excluded from being addressed under CERCLA?	☐	☒	☐
9. Is the site being addressed under RCRA corrective action or by the Nuclear Regulatory Commission?	☐	☒	☐
10. Is another federal, state, tribe or local government environmental cleanup program other than site assessment actively involved with the site (e.g., state voluntary cleanup program)?	☐	☒	☐
11. Is there sufficient documentation or evidence that demonstrates there is no likelihood of a significant release that could cause adverse environmental or human health impacts?	☐	☒	☐
12. Are there other site-specific situations or factors that warrant further CERCLA remedial/integrated assessment or response?	☐	☐	☒

Preparer's Recommendation: ☒ **Add** site to the Superfund Active site inventory.

☐ **Do not add** site to the Superfund Active site inventory.

Please explain recommendation below:

PCS Summary and Decision Rationale

Use this section to summarize PCS findings and support the decision to add or not add the site to the Superfund active site inventory for further investigation. Information does not need to be specific but, where known, can include key factors such as source and waste characteristics (e.g., drums, contaminated soil); evidence of release or potential release; threatened targets (e.g., drinking water wells); key sampling results (if available); CERCLA eligibility; involvement of other cleanup programs; and other supporting factors. Attach additional pages as necessary.

The Parcel J property contains lead in shallow soil above the state non-industrial direct contact limit. Limited site investigations showed that the top 2-4 feet of soil are contaminated. No groundwater contamination existed as of 2006; however TCLP and SPLP samples at the time showed the potential to leach lead into groundwater at concentrations 15 times higher than the enforcement standard. Due to a dispute over the lead source, the USACE (current owner) plans no further site investigation or remediation. Site work halted in 2006, and the nature/extent of lead contamination remain unknown. Potential receptors include residents by direct contact, drinking water, and the ecological food chain through plant and/or surface water uptake.

Site Description

(All text as entered on page A-2)

Parcel J is a strip of river bank no more than 46 feet wide, immediately upstream (west) of the Kaukauna City Dam and Power Canal, on the south side of the river. The property has more than a century of activity, dating back to 1885 with the Kaukauna Water Power Company, and likely before. As of 1910, a railroad spur and associated buildings existed on and adjacent to the property. The USACE took over supervision of river traffic in the late 1800s, and the property transferred to federal ownership in the early 1900s.

Photographs from the 1950s show a mostly wooded lot and existence of a small pond. Also according to aerial photographs, filling activities took place beginning in the 1960s, and an unimproved road existed until at least 1992. Since approximately 2000, residential apartment complexes neighbor the riverbank. The riverbank exists as partially-wooded grass yard as of 2019.

In the early 2000s, the USACE began transferring a series of properties along the Fox River to the State of Wisconsin, in order to upgrade and preserve historic locks once used for shipping commerce. At that time, several limited site investigations at Parcel J identified elevated levels of lead in soil from an unknown source. The property transaction (and site cleanup) stalled when the state required site remediation prior to taking ownership from the USACE. The last active site work ended in 2006.

The site investigations between 2003 and 2006 showed that lead existed (at the time) in shallow soil between 290 and 11,000 mg/kg, which is above Wisconsin's non-industrial direct contact standard of 250 mg/kg. Site soil is a mix of poorly-correlating unconsolidated river sediment, including sand, gravel, silt and clay in medium to very thick beds. Generally the site investigations extended to a depth of 10 feet or less, with lead concentrated in the top 2 to 4 feet.

The lead concentration in sediment is unknown for Parcel J; however, extensive sampling from the Fox River PCB dredging may exist in site investigations from other parcels.

Shallow groundwater samples contained lead below state enforcement standards of 15 ppb. However, SPLP and TCLP analysis showed the ability to leach lead to groundwater at concentrations above 150 ppb (15 times the enforcement standard). No groundwater wells exist at the site as of 2019.

The lead source is unknown. Potential sources may include the rail spur, lead paint removal, paint shop buildings and even a blacksmith shop that formerly existed on or near the property. The USACE maintains that they are not the causer, and despite ownership, have not completed lead delineation and cleanup.

Potential receptors include residents by direct contact, drinking water sources and the ecological food chain by uptake or leaching to surface water.

PCS Summary and Decision Rationale

(All text as entered on page A-4)

The Parcel J property contains lead in shallow soil above the state non-industrial direct contact limit. Limited site investigations showed that the top 2-4 feet of soil are contaminated. No groundwater contamination existed as of 2006; however TCLP and SPLP samples at the time showed the potential to leach lead into groundwater at concentrations 15 times higher than the enforcement standard. Due to a dispute over the lead source, the USACE (current owner) plans no further site investigation or remediation. Site work halted in 2006, and the nature/extent of lead contamination remain unknown. Potential receptors include residents by direct contact, drinking water, and the ecological food chain through plant and/or surface water uptake.

1.0 INTRODUCTION

The U.S. Environmental Protection Agency (EPA) tasked the Wisconsin Department of Natural Resources (WDNR) with completion of this Pre-CERCLIS Screening (PCS) and Preliminary Assessment (PA) at the USACE Parcel J site (the "Site"), in Outagamie County, Wisconsin. The assessment lies under authority of the Comprehensive Environmental Response Compensation Liability Act of 1980 (CERCLA), and the Superfund Amendments and Reauthorization Act of 1986 (SARA). The assessment falls within the fiscal-year 2019 – 2020 Cooperative Agreement between the U.S. EPA and the WDNR.

The PCS and PA document Site conditions and information sufficient to assess threats posed to human health and the environment, and to determine the need for additional CERCLA/SARA or other appropriate action. This scope includes a review of available file information, a comprehensive target survey and an on- and off-site reconnaissance. The PCS form is included in Appendix B.

2.0 SITE BACKGROUND

2.1 Location and Climate

The Site area lies along the Fox River's south bank in Kaukauna, Wisconsin (Figure 1). According to the WDNR Bureau of Remediation and Redevelopment Tracking System (BRRTS), the Site's latitude and longitude are 44.28139 North, 88.27615 West. The Site lies within the SE¼ of the NE¼ of section 23, T21N, R18E (Reference 1). The Outagamie County Interactive GIS website indicates that the Site parcel is approximately 1.07 acres in size as Parcel Identification Number 44331 (Figure 2 and Reference 2).

The climate of Outagamie County is continental and characterized by cold and typically snowy winters with moderate and humid summers. The average January temperatures range from 10^{o} to 25^{o} F and average July temperatures range from 62^{o} to 81^{o} F. The average annual precipitation is approximately 31 inches, including 45 inches of snow. (Reference 3).

2.2 Site Description

Figure 3 shows the site area and neighboring properties. The Site area lies within the physical flood plain of the Fox River, directly adjacent to the river. The site elevation is approximately 650 feet above mean sea level. The surrounding area includes residential, commercial and industrial properties, closely surrounded by apartment and municipal buildings. Former Site use includes shipping and related industries, including a rail yard. The site now exists as green space between private residences and the Fox River.

The tax parcel is a narrow and long 1.07 acre grass strip with no buildings or other structures. The ground surface is flat. Access to the area is unrestricted. It is used as grass yard space for the adjacent properties. Public utilities serve the site area. The photo log in Appendix C shows site pictures including adjacent neighbors.

The site is grass-covered with mature trees and occasional brick walkways. The river lies to the north. Municipal buildings, an apartment complex and commercial business line the eastern Site area, opposite the river. The Site is approximately 20 to 30 feet wide on the eastern portion. Multi-unit apartment complexes rim the western site area, where the property is as wide as 46 feet. Infrequent topsoil erosion occurs in areas with heavier usage. Similar housing units lie to the west, with similar grassed banks to the river.

2.3 Operational History and Waste Characteristics

Little is known about historic Site use. In 1872, the USACE acquired navigational control of the Fox River Waterway (Reference 4-1) and ownership of this and other properties along the river. Previous reports (Reference 4-2) describe the Site as being owned by the Kaukauna Water Power Company as of 1885. Through the early 1900s, shipping became more abundant in the Fox River, and locks were added to move and maintain boats and ships on nearby properties. In a 1910 map, the Site includes small buildings, a pond and a railroad spur. By the 1950s, the Site was wooded and all structures had been removed. Through the 1970s, fill activities occurred, and by the 1990s development had begun with roadways that led to the apartment complexes that exist adjacent to the current Site. The property was likely a small part of a larger property that was parceled off during development, and other nearby sites may have similar soil contamination.

In the 1980s, the State of Wisconsin began acquiring locks and adjacent properties from the USACE. Most other USACE parcels are now owned by the State of Wisconsin. Although the 2000 MOA between the State and USACE required the USACE to complete cleanup prior to property transfer, remediation activities stalled at Parcel J due to the USACE belief that the lead contamination was caused by a previous owner. Therefore, the USACE does believe they are the responsible party.

Historic usage is not well known, though it may be speculated that the area housed soil or other materials related to the shipping industry, as occurred with most neighboring properties. This property's use is not well documented; typical site use for neighboring properties included painting activities (including stripping and repainting), waste storage and shipping-related maintenance.

2.4 Regulatory Status

The site exists as an open case in the WDNR Environmental Repair Program (ERP), BRRTS No. 02-45-548419. There is no pending action by the USACE at this time due to a dispute about the responsible party.

The case began in 2002 with a notification of discharge for a series of USACE land parcels along the Fox River lock system. The state of Wisconsin agreed to take ownership of USACE parcels as part of a cleanup and restoration effort for the historic locks. Incomplete cleanup of lead contamination continues to prevent the closure and property transaction for Parcel J. The USACE pursued remediation efforts through 2008, when they decided that they would not pay for cleanup of contamination they do not believe they created. Under Wisconsin state law, both the causer and property owner are considered responsible parties.

The only complete investigation document in the case file is a 2006 Phase II investigation (Altech Environmental Services, July, 2006), which summarizes other previously investigative work. The case file also includes correspondence documents regarding cleanup and funding discussions with the property owner and the WDNR. No remediation plans or activities are documented.

2.5 Past Environmental Investigations

Following a recommended property transfer in 2002, three years of site evaluation and sampling led to a limited Phase 2 investigation at the property (Altech, 2006). Investigation was largely driven by the property transfer of various USACE properties associated with the Fox River and lock system.

The 2006 report summarizes sampling from 2003 – 2005. Sample data showed that lead existed in soil above the Wisconsin Administrative Code NR 720 Industrial Direct Contact Criteria at multiple samples,

at concentrations as high as 11,000 mg/kg. Soil results from previous investigations are provided in Table 1 and References 5-1 through 5-5, which include both summary tables and location figures.

2.6 Other Releases in the Area

Figure 4 shows the location of other nearby open and closed releases listed in BRRTS. Within 500 feet, there are two open sites and two closed sites, one with continuing obligations for notification of residual contamination. Another four sites lie between 500 and 1000 feet from the property, one of which remains open. Two closed sites have continuing obligations. Table 2 lists the properties and general descriptions of each cleanup.

The Fox River dredging project is a Superfund site related to removal of sediment contaminated with PCBs and metals. The river abuts the northern Site boundary. The sediment dredging project is one part of a general Fox River cleanup that includes restoration of various properties with lead contamination. It's likely that lead contamination in the river and the Site are both related to shipping and lead based paint that was applied to or removed from ships and boats. No PCBs are known to exist at the Site, and no PCB sampling is documented in the case file.

The Fox Shores Apartments case to the south has a similar situation and contaminants, likely due to the same unknown contributor. In addition, site soils contain PVOCs and PAHs. This case remains open and active.

The Ghost Town Fitness Center to the southeast had a minor detect of metals in a temporary monitoring well. Several metals (lead, selenium, arsenic) were detected above the state's Wis. Admin. Code NR 140 Preventive Action Limit. The well was abandoned and the case was closed with no action required.

Kaukauna City Waste Oil collected and stored waste oil for city residents. The case is closed with a continuing obligation to maintain a cover for soil contaminated with PVOCs.

Cases farther than 500 feet away either do not share similar contaminants, or are not similar in use or setting to the Parcel J site. The other remaining cases likely have little to no effect on the Site.

3.0 FIELD INSPECTION ACTIVITIES

BJ LeRoy from the WDNR completed the Site reconnaissance in July 2019. Appendix C includes a photo log compiled from site reconnaissance and prior site investigation materials. On the surface, the property looks like a backyard used by apartment residents for recreation. The yards are well kept and there are no visual signs of contamination or disrepair.

The USACE permitted site access for the inspection and photo log. No interview was completed due to previous work at the site.

The property is as described in Section 2.2; a long, narrow, mostly grass covered flat shoreline adjacent to the Fox River. There are no buildings or other structures on site. Vegetation covers the soil in most places as shown in the photographs. Some mature trees exist along the shoreline, with roots that occasionally break through the grass to the land surface. Directly along the shore, grass erodes to allow soil exposure. Yard use is heavier to the west where multi-unit apartment buildings line the property. To the east, the property appears nearly untouched, other than lawn mowing activity. More activity appears to occur on the northwest property where apartments exit to the yard, and picnic tables show typical wear and tear of heavy use with some exposed soil.

Gunderson Cleaners	0345402371	Open	CVOCs from dry cleaning operation.
Jim's Car Wash	0345000082	Closed	CVOC and metals in soil and groundwater from plating operations
Van Hoof Service LLC – Heating Oil	0345244868	Continuing Obligation	Petroleum in soil due to service station activities; required surface cap for groundwater and direct contact protection.
Van Hoof Oil and Service	0345002042	Continuing Obligation	Petroleum in soil due to service station activities; required surface cap for groundwater and direct contact protection.

The area contains mostly residential buildings to the west, and far south, with commercial, residential, municipal and light manufacturing to the east and near south. Residential buildings are typically 10 to 20-unit apartments surrounding the site. Farther to the south and southwest, single family homes form downtown neighborhoods.

City service buildings are in the near area, with fire, police, municipal, utility and highway buildings within a few blocks. To the east lies the downtown, with restaurants, taverns and other commercial businesses. Most downtown businesses are well kept and occupied. Traffic is light to moderate with personal cars and trucks at various homes and businesses.

River View Middle School is the nearest school, approximately 800 feet to the east. The closest daycares are over 2000 feet away.

Residences include approximately 12 multi-unit apartment buildings adjacent to the property, with approximately 200 total units. An additional 25 single family residences lie within ¼ mile of the property, and most of the City of Kaukauna lies within one mile, with a population of 16,246 as of 2018 (Reference 6).

The immediate surrounding area is a flat-lying flood plain of the Fox River. The river is the prominent physical feature in the Site area with several bridges and easy access for recreational activity. Lying directly north of the site, the river flows from west to east through the downtown as shown on Figure 1. Precipitation that doesn't infiltrate the ground flows to either the storm sewer or directly to the river. From the site, most precipitation likely flows to the storm sewer which discharges at various locations to the river.

The river represents the only mapped wetland and navigable waterway within 1000 feet of the site. Mapped wetlands typically do not intersect the property. According to the Wisconsin Surface Water Data Viewer, most soils at the site and surrounding area are not wetland indicating soils (Reference 7).

Fisherman use the river for a wide variety of sport fishing. However, the WDNR advises restricting fish consumption due to PCBs and mercury in the water and sediment. The river is considered in poor condition for fish and aquatic life, according to 2019 DNR reporting (Reference 8). No fisherman were observed during the site visit.

Groundwater is the principle water source for the City of Kaukauna and surrounding area (Reference 9). Five municipal wells serve the city with groundwater from bedrock aquifers consisting of Ordovician and Cambrian dolomite and sandstone. Municipal wells range in depth from 726 to 806 feet deep, with 120 to 239 feet of surface casing. Wells are sampled regularly with few violations and no significant contamination issues.

Four private potable wells reportedly exist within one mile of the site, with no wells closer than 1000 feet. The well logs and locations are included in Appendix D, Reference 10. Wells are screened between 76 and 82 feet below ground surface.

4.0 GROUNDWATER PATHWAY

4.1 Hydrogeologic Setting

Wisconsin lies in the Interior Plains Province and the Great Lakes Basin of the United States (Reference 11-1 and 11-2). The site lies in southeast Outagamie County within the Lower Fox River Basin, and the Garners Creek-Fox River Watershed (Reference 12). Wisconsinan-aged glaciers and subsequent drainage formed the basin's land surface into watersheds that eventually drain to Lake Michigan. The

watershed contains the Lower Fox River which flows west to east, directly adjacent to the Site area (Reference 13).

Site-area surficial deposits are typically low permeability lacustrine sand, silt and clay sediment (Reference 14). Sediments consist of varied deposits from shoreline to deep water lake sediment, to fluvial deposits of re-worked lake sediment. Local sediment thickness ranges from 0 to 100 feet thick in the area (Reference 15), typically less than 20 feet thick at the site (Reference 16).

The soil profile formed in the top few feet of glacial deposits is classified only as disturbed soil (udorthent, or Uo) at the site location. Adjacent soil is Kewaunee (KkE3), which is the likely predecessor to the anthropogenically disturbed soil. The USDA soil survey lists Kewaunee as a well drained, 0-6" thick soil formed from loess or clay till (Reference 17).

The uppermost bedrock consists of fractured and porous Ordovician dolomite or sandstone that form the upper regional aquifer. Bedrock dips slightly to the east toward Lake Michigan. Ordovician-aged dolomite overlies the Cambrian St. Peter Sandstone, a regional aquifer with high capacity and high use. (Reference 18).

Private potable wells screened in the aquifer range from approximately 76 to 568 feet in depth. Four private wells exist within one mile of the Site (Reference 19). Unconsolidated formation thickness ranges from 26 to 70 feet and is typically cased so that it is not used as a groundwater source. Drillers' notes most often include references to clay or hard pan, and infrequently note gravel. (Reference 10).

Five municipal wells surround the site, from 0.2 to one mile away (Reference 20). Wells range from 726 to 841 feet deep. The city draws approximately 1.2 million gallons of water per day (800 gallons per minute) (Reference 9). Municipal wells are screened in the Ordovician dolomite aquifer and the Cambrian sandstone aquifer.

4.2 Site Conceptual Model

The Site lies in a discharge zone, directly adjacent to the Fox River. Water enters the site through precipitation and upland flow. Most precipitation likely flows overland to the river. A small amount of precipitation may infiltrate the ground surface and recharge the water table, which is approximately 5 feet below ground surface (Reference 16).

Local and shallow groundwater generally flows to the site area from the south. The Fox River dominates the shallow local flow system, accepting discharge from groundwater. Shallow Site groundwater flows northward to the river. Some shallow groundwater may also migrate downward from the shallow unconsolidated system to recharge the uppermost aquifer.

Regionally, topographic highs formed by dolomite bedrock create recharge areas where infiltration migrates to groundwater and flows generally toward the Fox River (Reference 21).

4.3 Groundwater Targets

The population within a 4-mile radius, approximately 51,882 people (Reference 22), relies primarily on groundwater as a water source. Approximately one third of this population lives within the Kaukauna city limits, where residents are assumed to be using municipally-supplied water. The City of Kaukauna groundwater supply comes from five wells located within one mile of the site (Reference 20). Four wells lie between ½ and 1 mile from the site, and one well is within approximately 1/3rd of a mile away. Four wells City wells are screened in the Ordovician dolomite aquifer and Cambrian sandstone aquifer. City well water is blended from the five wells and redistributed as needed to the City of Kaukauna.

In addition, water supply wells for the Kimberly, Darboy and Little Chute lie between two and four miles to the northeast, east and southeast (Reference 20). Two wells are just inside 2 miles away; two wells are between 2 and 3 miles away; four wells lie between 3 and 4 miles from the site. The wells are screened between 525 and 805 feet below ground surface, which is a consistent elevation with wells in Kaukauna. Screened formations include Ordovician dolomite and sandstone, and Cambrian sandstone. Wells in these three communities lie upgradient from the Parcel J site.

Five high capacity wells exist within 4 miles of the property, each used for non-potable sources. Three golf courses, a race track and the Kaukauna water utility use high capacity wells as process water for various operations.

The rural population within 4 miles relies primarily on private residence wells. Approximately 760 residences (Reference 23) reportedly use private well water within 4 miles. The WDNR was unable to determine which of these wells still exist. However, wells outside the city limits are assumed to be continuing water sources. Approximately half the area lies outside city limits. Two potential private drinking water wells lie approximately 1000 feet from the Site (Reference 19).

Table 3 lists approximate populations served by wells within specific radii of the Site area. A WDNR GIS specialist used ESRI Community Analyst to estimate populations within each area. The total population within the four-mile radius of the Site is approximately 51,882 people (Reference 22). Populations between 1-2 miles, 2-3 miles and 3-4 miles are based on ESRI Community analyst estimates. Associated maps are attached as Figures 5 and 6.

Current municipal wells are sampled for a variety of parameters. Water samples from five municipal wells indicate no violations in the public water supply (Reference 9). The city does not typically sample the public water supply for lead. No other signs of contamination exists in sample results from recent groundwater sampling events.

4.4 Groundwater Conclusions

A known, observed lead release from the Site exists in shallow soil, but has not been linked to groundwater. No monitoring well data exists for the Site. Lead is a naturally occurring substance in Wisconsin, and can be found in groundwater at low levels. Little to no data exists in the Site area that could be correlated with the Site. To date, the Site area, geologic and hydrogeologic characteristics, and nature and extent of contamination have been studied on a limited basis and are not well defined.

5.0 SURFACE WATER PATHWAY

5.1 Hydrologic Setting

Site area topography is flay lying within the physical flood plain of the Lower Fox River (Reference 1). Precipitation drains overland, primarily to the river due to its proximity. The river itself lies directly adjacent to the Site. Due to ample groundwater availability and local use advisories including PCBs, the river is not used as a source of potable water, and it is not considered a valuable sport fishing waterway (Reference 8). Within the region's watershed, topographic highs on either side of the river valley guide runoff toward the river. The Fox River drains directly to Lake Michigan in Green Bay, approximately 24 miles from the Site.

5.2 Surface Water Targets

Table 3
Population Summary

Radius from Site Area	0-0.25 Mile	0.25-0.5 Mile	0.5-1 Mile	1-2 Miles	2-3 Miles	3-4 Miles	Total
Population Inside Specific Radius [1,2]	450	1,982 (2,432)	6681 (9113)	13,019 (22,132)	15,400 (37,532)	14,350 (51,882)	51,882
Approximate Number of Households[2]	271	830 (1,101)	2,790 (3,891)	5,201 (9,092)	5,890 (14,982)	5,389 (20,371)	20,371
Number of Private Wells[3]	2	2 (4)	29 (33)	108 (141)	297 (438)	322 (760)	760
Modified Groundwater Population [4]	5	3,856 (3,861)	15,473 (19,333)	7,961 (27,394)	12,264 (39,558)	12,324 (51,882)	51,882

1 - The two numbers in each cell represent the total inside the specific radius (total cumulative inside radius).

2 – Reference 22

3 – Reference 23

4 – Modified groundwater population (each cell denoted by specific radius/cumulative); private well users plus the number of people served by city wells inside the radius

The river system does not supply drinking water due to ample groundwater supply and widespread chemical water advisories. The WDNR advises sport fishers not to over-consume fish from the Fox River and its downstream watershed (Reference 24).

No recorded wetlands lie in the Site's near vicinity (Reference 25), other than the river itself. At the site and throughout the area, most soil is considered disturbed land. Wetland-indicating soils exist father downstream, and farther away from the river valley where the property hasn't been anthropogenically disturbed (Reference 26). Area soil lies flat and drains poorly. According to the FEMA Flood Insurance Map database, the Site has a minimal chance of flooding in a given year, likely due to dams and proximity to the river mouth (Reference 27).

The WDNR identified endangered resources that have been recorded in the Site vicinity. This list and information are taken from the state's Natural Heritage Inventory (NHI) database, which also includes federally threatened and endangered species. This evaluation includes both the project area and a buffer of one mile for terrestrial and wetland species and a two-mile buffer for aquatic species. Descriptions are generalized due to using confidential data from the NHI database.

The database indicates three bald eagle nest sites within one mile of the project area, although none are within the United State Fish and Wildlife Service buffer of 660 feet. The bald eagle is federally protected through the Bald and Golden Eagle Protection Act, and could be exposed to lead through the uptake of organisms (primarily fish) or through surface water use.

The site is approximately 2000 feet from a migratory bird concentration site. Migratory bird concentration sites are important resting and feeding areas for birds as they fly between their breeding and wintering grounds. These areas also can be locations where large numbers of migrating birds often become concentrated due to prevailing winds and/or water barriers. Sites are used by many different species, both rare and non-rare. Birds using this area as a migratory stopover could be exposed to lead through the uptake of organisms or through surface water use.

A state endangered bird has also been recorded within one mile of the project area. This species could be exposed to lead through the uptake of organisms (primarily other birds) or through surface water use.

5.3 Surface Water Conclusions

No visual observation of contamination exists at the site or near vicinity. There is little likelihood of a further release due to overland flow or runoff.

The site lies in a discharge area within the shallow groundwater system directly adjacent to the Fox River. Previous studies, while limited, indicate that contamination exists in shallow soil and may be exposed to humans or the environment through erosion, and migration into the Fox River. There is no current evidence that this does (or doesn't) occur. The lack of flood potential and low permeability of soils indicate that surface water may be a limited migration pathway.

6.0 SOIL EXPOSURE, SUBSURFACE INTRUSION, AND AIR PATHWAYS

6.1 Physical Conditions

Lead soil contamination at the Site exists in the top four feet of soil, where it may pose a threat via subsurface migration or direct contact threat to building residents or trespassers. Lead does not pose a subsurface vapor intrusion or air pathway hazard.

The property is a mostly grass strip between apartment complexes and the Fox River. A dozen multi-unit apartments neighbor the Site, while the farther surrounding area is mixed residential, commercial and industrial with light to medium street traffic. The property itself is unsecured, though fairly private due to the river and the apartments buildings. Grass typically covers the soil, except in high-wear areas like walkways and near picnic tables.

Soil samples collected from the upper four feet exceed Wisconsin Administrative Code ch. NR 720 residual contamination levels (RCLs) for direct contact (Reference 5, Table 1). Seven soil samples range from 290 to 11,000 mg/kg of lead, well above the soil industrial and non-industrial RCLs of 800 and 400 mg/kg.

An adjacent investigation at Fox Shores Apartments identified lead in soil as high as 960 mg/kg. A second adjacent investigation at Ghost Town Fitness showed discovered only background lead concentrations in soil. No other neighboring properties have been sampled to DNR knowledge.

6.2 Soil, Subsurface Intrusion, and Air Targets

Site access is generally unrestricted, with a risk of direct contact exposure to passers-by or trespassers due to shallow soil contamination. Residents in the buildings are at higher risk for direct contact due to a higher exposure frequency. The number of adjacent apartment complexes also presents a higher risk factor.

Table 3 lists population statistics inside radii from ¼ to 4 miles. Within 50 feet, approximately 480 people live in adjacent apartment complexes. Most soil results reported in Table 1 are within 50 feet on at least one apartment building. The closest school/daycare is over 800 feet away.

6.3 Soil Exposure, Subsurface Intrusion, and Air Conclusions

While there are high concentrations of lead in soil in the unsaturated zone within four feet of the ground surface, subsurface vapor intrusion and air are not viable pathways due to the stability of lead as a solid.

7.0 SUMMARY AND CONCLUSIONS

Limited investigations at the USACE Parcel J Site show that significant lead contamination exists in shallow soil. No site groundwater results exist to date, because no monitoring wells have ever been installed on-Site. The nature and extent of lead is not well defined at depth or in other media, as previous investigations were limited in scope.

The direct contact pathway provides a route to receptors, particularly the residents in apartment complexes that line the Site perimeter. Surface water may also provide a completed pathway with the proximity of the Fox River, and the existence of uncontrolled lead in near-surface soil. The groundwater pathway is potentially complete due to a shallow water table and the bedrock aquifer system. The subsurface vapor intrusion and air pathways are not complete due to the nature of lead as a contaminant.

Site Description

Use this section to briefly describe site background and conditions if known or (easily) available, such as: operational history; physical setting and land use; site surface description, soils, geology and hydrogeology; source and waste characteristics; hazardous substances/contaminants of concern; historical releases, previous investigations and cleanup activities; previous regulatory actions, including permitting and enforcement actions; institutional controls; and community interest.

Parcel J is a strip of river bank no more than 46 feet wide, immediately upstream (west) of the Kaukauna City Dam and Power Canal, on the south side of the river. The property has more than a century of activity, dating back to 1885 with the Kaukauna Water Power Company, and likely before. As of 1910, a railroad spur and associated buildings existed on and adjacent to the property. The USACE took over supervision of river traffic in the late 1800s, and the property transferred to federal ownership in the early 1900s.

Photographs from the 1950s show a mostly wooded lot and existence of a small pond. Also according to aerial photographs, filling activities took place beginning in the 1960s, and an unimproved road existed until at least 1992. Since approximately 2000, residential apartment complexes neighbor the riverbank. The riverbank exists as partially-wooded grass yard as of 2019.

Geospatial Information

Latitude: +44.281215 **Longitude:** -88.276265

Decimal Degree North (e.g., 38.859156) Decimal Degree West (e.g., 77.036783)

Provide 4 significant digits at a minimum, more if your collection method generates them.

Except for certain territories in the Pacific Ocean, all sites in U.S. states and territories are located within the northern and western hemispheres and will have a positive latitude sign and negative longitude sign. Coordinate signs displayed above are based on the State/Territory entry on page A-1. Geospatial data tips from the PCS Guidance document are available **here**.

Point Description: Select the option below that best represents the site point for future reference and to distinguish it from any nearby sites. See additional information **here**.

- ☐ Geocoded (address-matched) Site Address
- ☐ Site Entrance (approximate center of curb-cut)
- ☒ Approximate Center of Site
- ☐ Other Distinguishing Site Feature (briefly describe):

Point Collection Method: Check the method used to collect the coordinates above and enter the date of collection. See additional information **here**.

- ☒ Online Map Interpolation
- ☐ GPS (handheld, smartphone, other device or technology with accuracy range < 25 meters)
- ☐ GPS Other (accuracy range is ≥ 25 meters or unspecified)
- ☐ Address Matching: Urban
- ☐ Address Matching: Rural
- ☐ Other Method (briefly describe below):

Collection Date (mm/dd/yyyy): 04/15/2019

POINT-SELECTION CONSIDERATIONS

- Often the best point is a feature associated with the environmental release or that identifies the site visually.
- Use the curb cut of the entrance to the site if there is a clear primary entrance and it is a good identifier for the overall location.
- The approximate center of the site (a guess at the centroid) is useful for large-area sites or where there are no appropriate distinguishing features.
- Use the geocoded address if that is the only or best option available, but if possible use something more representative for sites larger than 50 acres.

Complete this checklist to help determine if a site should be added to the Superfund Active site inventory. See Section 3.6 of the PCS guidance for additional information.	YES	NO	Unknown
1. An initial search for the site in EPA's Superfund active, archive and non-site inventories should be performed prior to starting a PCS. Is this a new site that does not already exist in these site inventories?	☒	☐	☐
2. Is there evidence of an actual release or a potential to release?	☐	☐	☐
3. Are there possible targets that could be impacted by a release of contamination at the site?	☒	☐	☐
4. Is there documentation indicating that a target has been exposed to a hazardous substance released from the site?	☒	☐	☐
5. Is the release of a naturally occurring substance in its unaltered form, or is it altered solely through naturally occurring processes or phenomena, from a location where it is naturally found?	☒	☐	☐
6. Is the release from products which are part of the structure of, and result in exposure within, residential buildings or business or community structures?	☐	☐	☐
7. If there has been a release into a public or private drinking water supply, is it due to deterioration of the system through ordinary use?	☐	☐	☐
8. Are the hazardous substances possibly released at the site, or is the release itself, excluded from being addressed under CERCLA?	☐	☐	☐
9. Is the site being addressed under RCRA corrective action or by the Nuclear Regulatory Commission?	☐	☐	☐
10. Is another federal, state, tribe or local government environmental cleanup program other than site assessment actively involved with the site (e.g., state voluntary cleanup program)?	☐	☒	☐
11. Is there sufficient documentation or evidence that demonstrates there is no likelihood of a significant release that could cause adverse environmental or human health impacts?	☐	☒	☐
12. Are there other site-specific situations or factors that warrant further CERCLA remedial/integrated assessment or response?	☐	☐	☒

Preparer's Recommendation: ☒ **Add** site to the Superfund Active site inventory.

☐ **Do not add** site to the Superfund Active site inventory.

Please explain recommendation below:

PCS Summary and Decision Rationale

Use this section to summarize PCS findings and support the decision to add or not add the site to the Superfund active site inventory for further investigation. Information does not need to be specific but, where known, can include key factors such as source and waste characteristics (e.g., drums, contaminated soil); evidence of release or potential release; threatened targets (e.g., drinking water wells); key sampling results (if available); CERCLA eligibility; involvement of other cleanup programs; and other supporting factors. Attach additional pages as necessary.

The Parcel J property contains lead in shallow soil above the state non-industrial direct contact limit. Limited site investigations showed that the top 2-4 feet of soil are contaminated. No groundwater contamination existed as of 2006; however TCLP and SPLP samples at the time showed the potential to leach lead into groundwater at concentrations 15 times higher than the enforcement standard. Due to a dispute over the lead source, the USACE (current owner) plans no further site investigation or remediation. Site work halted in 2006, and the nature/extent of lead contamination remain unknown. Potential receptors include residents by direct contact, drinking water, and the ecological food chain through plant and/or surface water uptake.

Site Description

(All text as entered on page A-2)

Parcel J is a strip of river bank no more than 46 feet wide, immediately upstream (west) of the Kaukauna City Dam and Power Canal, on the south side of the river. The property has more than a century of activity, dating back to 1885 with the Kaukauna Water Power Company, and likely before. As of 1910, a railroad spur and associated buildings existed on and adjacent to the property. The USACE took over supervision of river traffic in the late 1800s, and the property transferred to federal ownership in the early 1900s.

Photographs from the 1950s show a mostly wooded lot and existence of a small pond. Also according to aerial photographs, filling activities took place beginning in the 1960s, and an unimproved road existed until at least 1992. Since approximately 2000, residential apartment complexes neighbor the riverbank. The riverbank exists as partially-wooded grass yard as of 2019.

In the early 2000s, the USACE began transferring a series of properties along the Fox River to the State of Wisconsin, in order to upgrade and preserve historic locks once used for shipping commerce. At that time, several limited site investigations at Parcel J identified elevated levels of lead in soil from an unknown source. The property transaction (and site cleanup) stalled when the state required site remediation prior to taking ownership from the USACE. The last active site work ended in 2006.

The site investigations between 2003 and 2006 showed that lead existed (at the time) in shallow soil between 290 and 11,000 mg/kg, which is above Wisconsin's non-industrial direct contact standard of 250 mg/kg. Site soil is a mix of poorly-correlating unconsolidated river sediment, including sand, gravel, silt and clay in medium to very thick beds. Generally the site investigations extended to a depth of 10 feet or less, with lead concentrated in the top 2 to 4 feet.

The lead concentration in sediment is unknown for Parcel J; however, extensive sampling from the Fox River PCB dredging may exist in site investigations from other parcels.

Shallow groundwater samples contained lead below state enforcement standards of 15 ppb. However, SPLP and TCLP analysis showed the ability to leach lead to groundwater at concentrations above 150 ppb (15 times the enforcement standard). No groundwater wells exist at the site as of 2019.

The lead source is unknown. Potential sources may include the rail spur, lead paint removal, paint shop buildings and even a blacksmith shop that formerly existed on or near the property. The USACE maintains that they are not the causer, and despite ownership, have not completed lead delineation and cleanup.

Potential receptors include residents by direct contact, drinking water sources and the ecological food chain by uptake or leaching to surface water.

PCS Summary and Decision Rationale

(All text as entered on page A-4)

The Parcel J property contains lead in shallow soil above the state non-industrial direct contact limit. Limited site investigations showed that the top 2-4 feet of soil are contaminated. No groundwater contamination existed as of 2006; however TCLP and SPLP samples at the time showed the potential to leach lead into groundwater at concentrations 15 times higher than the enforcement standard. Due to a dispute over the lead source, the USACE (current owner) plans no further site investigation or remediation. Site work halted in 2006, and the nature/extent of lead contamination remain unknown. Potential receptors include residents by direct contact, drinking water, and the ecological food chain through plant and/or surface water uptake.

USACE Parcel J

1.3 SITE HISTORY

In 1872, the USACE acquired navigational control of the Fox River waterway, between the cities of Menasha and De Pere, Wisconsin for commercial navigational needs for the Fox River.

Kaukauna Lock 3, one of 17 lift locks on the Lower Fox River lock system, was built by the USACE in 1879. By the 1940s, the Fox River, which originally played a major role in regional transportation and commerce, saw a major decline in navigation with the advent of railroads and highways. In 1983, the USACE closed the Lower Fox River to commercial traffic and discontinued operation and maintenance of the locks (including Kaukauna Lock 3) and placed its property holdings (including Parcel F at Kaukauna Lock 3) in caretaker status. The USACE continues to own and operate nine federal dams and retain control over four privately-owned dams on the Lower Fox River as part of its flood control responsibilities.

Beginning in the 1980's, an effort began to transfer ownership of the locks from the USACE to the State of Wisconsin with the goal of renovating and reopening the locks for commercial and recreational boating. A MOA was signed on September 11, 2000 (USACE 2015) by the Wisconsin Governor, the Secretary of the WDNR, and the Assistant Secretary of the Army for Civil Works. In the MOA, the federal government agreed to "complete any necessary remediation action required by the CERCLA.

On September 17, 2004, the USACE began transferring the ownership of the 17 locks, 38 ha (94 ac) of land bordering the Lower Fox River, three harbors, and an assortment of related buildings along the Lower Fox River to the Wisconsin DOA. The transfer of the locks excluded Parcel F at Kaukauna Lock 3 (Figure 2), due to the presence of lead contamination in soil, which is the subject of this response action.

1.3.1 Previous Investigations and Remedial Activities

Elevated concentrations of lead were detected in soil on the sloped western portion of Parcel F (between the dry dock and garage/storage shed). This lead contamination is likely the result of historic scraping of lead-based paint from exterior walls of the wooden structures located on the parcel and/or historic maintenance of boats in the boat dry dock.

Several investigations and remedial activities were conducted by USACE on Parcel F at Kaukauna Lock 3 to evaluate the potential for, delineate the extent of, and address lead contamination in the vicinity of site building structures. Historic sample locations and excavation footprints are shown on Figure 3 and prior analytical results are listed in Tables 1 and 2. No background samples for lead in soil were collected during these investigations.

1.3.2 Recent Remedial Activities

Based on the results of previous investigations, the USACE issued an Action Memorandum for a Time-Critical Removal Action for the removal of Lead contamination from Parcel F at Kaukauna Lock 3 in June 2015 (USACE 2015). The proposed scope of work called for the deconstruction of the storage building and adjacent catwalk along with removal, transportation and disposal of asbestos bearing materials from the storage building. Additionally, lead contaminated soil along the western side of Parcel F and contaminated sediments within the dry dock area exhibiting lead levels

Dam, and Property Northeast of the Dam. These Property features are located on Canal and Augustine Streets in Kaukauna, Wisconsin. The Property parcels cover 50.4 acres. The layout of the Property is shown on Figure 5.

5.5.2 Property History

Locks 1, 2, 3, 4, and 5 were built in 1883, 1903, 1879, 1879, and 1898, respectively. The portion of the Lock 3 Property now supporting the Project Office and the Generator Building was acquired by the U.S. Government in 1947 by condemnation procedures. Current and known historical structure locations are shown on Figure 5.

Property Southwest of Dam

The Property southwest of the dam was depicted as part of the Kaukauna Water Power Company canal system in the 1885 Sanborn Map. The 1910 U.S. Government Map shows a small building with a well (purpose unknown), railroad spur, and a water closet. In 1952, 1956, and 1964, the Property was wooded, contained a small pond, and no structures. Surface disturbances were observed at the Property on the 1964 aerial photograph which may have been filling activities. The area of disturbance was larger in the 1971 aerial photograph. The 1974 historic map and 1992 topographic map show an unimproved roadway on the Property. This roadway is not apparent in the 1981 aerial photograph. In the 1992 aerial photograph, a square-shaped disturbance and driveway on the southeast portion of this Property are apparent. The locations of the disturbed areas are shown on Figure 5.

Property Northeast of Dam

From 1885 to 1951, the Property northeast of the dam contained small buildings/sheds related to the commercial establishments on Wisconsin Street. A "needle house" and "Guard Lock Skeleton Gates" were shown on the 1910 U.S. Government Map. From 1952 to 1964, this Property was open and vacant. In 1971, the Property was disturbed to construct an access road onto the Property.

Lock 1

The 1885, 1890, 1894, 1900, and 1906 Sanborn Maps show small outbuildings related to the adjoining lumber, paper, and hub-and-spoke manufacturing facilities on Lock 1 Property. The maps also show flumes related to these facilities crossing the Property and draining into the U.S. Canal. The 1910 U.S. Government Map shows a coal shed, warehouse, Lockmaster's dwelling, and barn immediately north of Lock 1. Small buildings associated with neighboring properties to the north of Lock 1, including a machine shop, are also shown on the Property. Buildings associated with the Union Bar and Paper Co. and Thilmany Paper Mill are also shown on the Property south of Lock 1. The neighboring property buildings on the northern portion of the Lock 1 Property remained on the Property until at least 1925. These buildings, including the machine shop, were removed from the Property by 1945. The 1952 and subsequent aerial photographs, and the 1956 Sanborn Map show an access road for Thilmany Paper on the southern shore of the Lock 1 Property. The areas of the Property used by adjacent commercial and industrial facilities are shown on Figure 5. In the 1981 aerial photograph, the large oil house, Lockmaster's dwelling, and garage are observed. The 1992 aerial photograph also shows a circular structure and a small area of surface disturbance/debris along the canal bank. The purpose of the circular structure is not known. During the site visit, the Lockmaster's dwelling, garage, large oil house, small oil house, and a lockshelter were observed at the Property.

ANNUAL WATER QUALITY REPORT

WATER TESTING PERFORMED IN 2017

Reference 9
Kaukauna Public Water Report
USACE Parcel F

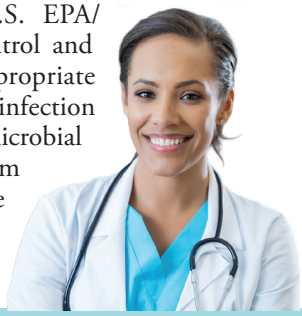
PWS ID#: 44503360

Quality First

Once again we are pleased to present our annual water quality report. As in years past, we are committed to delivering the best-quality drinking water possible. To that end, we remain vigilant in meeting the challenges of new regulations, source water protection, water conservation, and community outreach and education while continuing to serve the needs of all of our water users. Thank you for allowing us the opportunity to serve you and your family.

We encourage you to share your thoughts with us on the information contained in this report. After all, well-informed customers are our best allies.

Information on the Internet



The U.S. EPA (https://goo.gl/TFAMKc) and the Centers for Disease Control and Prevention (www.cdc.gov) Web sites provide a substantial amount of information on many issues relating to water resources, water conservation, and public health. Also, the Wisconsin Department of Natural Resources has a Web site (dnr.wi.gov/topic/drinkingwater) that provides complete and current information on water issues in Wisconsin, including valuable information about our watershed.

How Is My Water Treated and Purified?

The treatment process consists of a series of steps. First, raw water is pumped from our wells and sent to the filter plant, where we add potassium permanganate and manganese sulfate to the water before it reaches the filter tank. The addition of these substances oxidizes the iron, causing small particles to adhere to one another (called floc), which makes the particles big enough to be filtered out as the water passes through the layers of anthracite and manganese greensand in the filter tank. This process removes the iron and also reduces the radium levels in the drinking water. Then we add chlorine to the water for disinfection. Finally, the water is pumped to the distribution system.

Important Health Information

Some people may be more vulnerable to contaminants in drinking water than the general population. Immunocompromised people such as those with cancer undergoing chemotherapy, those who have undergone organ transplants, people with HIV/AIDS or other immune system disorders, some elderly, and infants may be particularly at risk from infections. These people should seek advice about drinking water from their health care providers. The U.S. EPA/CDC (Centers for Disease Control and Prevention) guidelines on appropriate means to lessen the risk of infection by *Cryptosporidium* and other microbial contaminants are available from the Safe Drinking Water Hotline at (800) 426-4791 or http://water.epa.gov/drink/hotline.

Water Conservation

You can play a role in conserving water and save yourself money in the process by becoming conscious of the amount of water your household is using and by looking for ways to use less whenever you can. It is not hard to conserve water. Here are a few tips:

- Automatic dishwashers use 15 gallons for every cycle, regardless of how many dishes are loaded. So get a run for your money and load it to capacity.
- Turn off the tap when brushing your teeth.
- Check every faucet in your home for leaks. Just a slow drip can waste 15 to 20 gallons a day. Fix it and you can save almost 6,000 gallons per year.
- Check your toilets for leaks by putting a few drops of food coloring in the tank. Watch for a few minutes to see if the color shows up in the bowl. It is not uncommon to lose up to 100 gallons a day from an invisible toilet leak. Fix it and you save more than 30,000 gallons a year.
- Use your water meter to detect hidden leaks. Simply turn off all taps and water-using appliances. Then check the meter after 15 minutes. If it moved, you have a leak.

Source Water Assessment

The Department of Natural Resources conducted assessments for all drinking water sources across the state. The purpose of the assessments was to determine the susceptibility of each drinking water source to potential contaminant sources and establish a relative susceptibility rating of High, Moderate, or Low for each source. The Kaukauna Utilities system is susceptible to contamination by volatile organic compounds, nitrate, beryllium, and microbes. The system has Moderate susceptibility to contamination by synthetic organic compounds (SOCs). The system has Low susceptibility to ethylene dibromide (EDB). For additional information on the source water assessment, call Jeff Helmuth at (608) 266-5234.

QUESTIONS?

For more information about this report, or for any questions relating to your drinking water, please call Kevin Obiala, Water Department Superintendent, at (920) 462-0233.

Where Does My Water Come From?

The source of Kaukauna Utilities water is five groundwater wells that are located throughout the city. The depths of the wells range from 500 to 850 feet. Our daily pumping averages around 1.2 million gallons a day, which calculates to 438 million gallons of treated water a year. We have the capability of pumping in excess of 4 million gallons a day. The distribution system consists of approximately 100 miles of water main, ranging from 6 to 16 inches in diameter. We have three iron filters, which serve the dual purpose of removing both iron and radium from the water. We have two water towers, one on the north side and one on the south side of the city, each with a capacity of 500,000 gallons. We also have three underground reservoirs, with a combined capacity of 600,000 gallons of water.

Benefits of Chlorination

Disinfection, a chemical process used to control disease-causing microorganisms by killing or inactivating them, is unquestionably the most important step in drinking water treatment. By far the most common method of disinfection in North America is chlorination.

Before communities began routinely treating drinking water with chlorine (starting with Chicago and Jersey City in 1908), cholera, typhoid fever, dysentery, and hepatitis A killed thousands of U.S. residents annually. Drinking water chlorination and filtration have helped to virtually eliminate these diseases in the U.S. Significant strides in public health are directly linked to the adoption of drinking water chlorination. In fact, the filtration of drinking water plus the use of chlorine is probably the most significant public health advancement in human history.

How chlorination works:

Potent Germicide Reduction in the level of many disease-causing microorganisms in drinking water to almost immeasurable levels.

Taste and Odor Reduction of many disagreeable tastes and odors like foul-smelling algae secretions, sulfides, and odors from decaying vegetation.

Biological Growth Elimination of slime bacteria, molds, and algae that commonly grow in water supply reservoirs, on the walls of water mains, and in storage tanks.

Chemical Removal of hydrogen sulfide (which has a rotten egg odor), ammonia, and other nitrogenous compounds that have unpleasant tastes and hinder disinfection. It also helps to remove iron and manganese from raw water.

Community Participation

You are invited to participate in our public forum and voice your concerns about your drinking water. We meet the third Wednesday of each month beginning at 4 p.m. at Kaukauna Utilities Operations Building, 777 Island Street, Kaukauna, WI.

Count on Us

Delivering high-quality drinking water to our customers involves far more than just pushing water through pipes. Water treatment is a complex, time-consuming process. Because tap water is highly regulated by state and federal law, water treatment plant and system operators must be licensed and are required to commit to long-term, on-the-job training before becoming fully qualified. Our licensed water professionals have a basic understanding of a wide range of subjects including mathematics, biology, chemistry, and physics. Some of the tasks they complete on a regular basis include:

- Operate and maintain equipment to purify and clarify water
- Monitor and inspect machinery, meters, gauges, and operating conditions
- Conduct tests and inspections on water and evaluate the results
- Maintain optimal water chemistry
- Apply data to formulas that determine treatment requirements, flow levels, and concentration levels
- Document and report test results and system operations to regulatory agencies
- Serve our community through customer support, education, and outreach
- So the next time you turn on your faucet, think of the skilled professionals who stand behind each drop.

Water Main Flushing

Distribution mains (pipes) convey water to homes, businesses, and hydrants in your neighborhood. The water entering distribution mains is of very high quality; however, water quality can deteriorate in areas of the distribution mains over time. Water main flushing is the process of cleaning the interior of water distribution mains by sending a rapid flow of water through the mains.

Flushing maintains water quality in several ways. For example, flushing removes sediments like iron and manganese. Although iron and manganese do not themselves pose health concerns, they can affect the taste, clarity, and color of the water. Additionally, sediments can shield microorganisms from the disinfecting power of chlorine, contributing to the growth of microorganisms within distribution mains. Flushing helps remove stale water and ensures the presence of fresh water with sufficient dissolved oxygen, disinfectant levels, and an acceptable taste and smell.

During flushing operations in your neighborhood, some short-term deterioration of water quality, though uncommon, is possible. You should avoid tap water for household uses at that time. If you do use the tap, allow your cold water to run for a few minutes at full velocity before use, and avoid using hot water, to prevent sediment accumulation in your hot water tank.

Please contact us if you have any questions or if you would like more information on our water main flushing schedule.

Substances That Could Be in Water

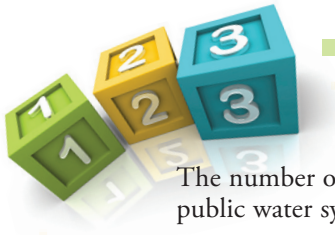
To ensure that tap water is safe to drink, the U.S. EPA prescribes regulations limiting the amount of certain contaminants in water provided by public water systems. U.S. Food and Drug Administration regulations establish limits for contaminants in bottled water that must provide the same protection for public health. Drinking water, including bottled water, may reasonably be expected to contain at least small amounts of some contaminants. The presence of these contaminants does not necessarily indicate that the water poses a health risk.

The sources of drinking water (both tap water and bottled water) include rivers, lakes, streams, ponds, reservoirs, springs, and wells. As water travels over the surface of the land or through the ground, it dissolves naturally occurring minerals, in some cases, radioactive material, and substances resulting from the presence of animals or from human activity. Substances that may be present in source water include:

Microbial Contaminants, such as viruses and bacteria, which may come from sewage treatment plants, septic systems, agricultural livestock operations, or wildlife;

Inorganic Contaminants, such as salts and metals, which can be naturally occurring or may result from urban stormwater runoff, industrial or domestic wastewater discharges, oil and gas production, mining, or farming;

Pesticides and Herbicides, which may come from a variety of sources such as agriculture, urban stormwater runoff, and residential uses;



Organic Chemical Contaminants, including synthetic and volatile organic chemicals, which are by-products of industrial processes and petroleum production and may also come from gas stations, urban stormwater runoff, and septic systems;

Radioactive Contaminants, which can be naturally occurring or may be the result of oil and gas production and mining activities.

For more information about contaminants and potential health effects, call the U.S. EPA's Safe Drinking Water Hotline at (800) 426-4791.

How Is My Water Treated and Purified?

The treatment process consists of a series of steps. First, raw water is pumped from our wells and sent to the filter plant, where we add potassium permanganate and manganese sulfate to the water before it reaches the filter tank. The addition of these substances oxidizes the iron, causing small particles to adhere to one another (called floc), which makes the particles big enough to be filtered out as the water passes through the layers of anthracite and manganese greensand in the filter tank. This process removes the iron and also reduces the radium levels in the drinking water. Then we add chlorine to the water for disinfection. Finally, the water is pumped to the distribution system.

BY THE NUMBERS

34 BILLION — The number of gallons of water produced daily by public water systems in the U.S.

1 MILLION — The number of miles of drinking water distribution mains in the U.S.

135 BILLION — The amount of money spent annually on maintaining the public water infrastructure in the U.S.

300 MILLION — The number of Americans who receive water from a public water system.

2 BILLION — The age in years of the world's oldest water found in a mine at a depth of nearly two miles.

Test Results

Our water is monitored for many different kinds of substances on a very strict sampling schedule. The information in the data tables shows only those substances that were detected between January 1 and December 31, 2017. Remember that detecting a substance does not necessarily mean the water is unsafe to drink; our goal is to keep all detects below their respective maximum allowed levels. The state recommends monitoring for certain substances less often than once per year because the concentrations of these substances do not change frequently. In these cases, the most recent sample data are included, along with the year in which the sample was taken.

We participated in the 3rd stage of the U.S. EPA's Unregulated Contaminant Monitoring Rule (UCMR3) program by performing additional tests on our drinking water. UCMR3 benefits the environment and public health by providing the EPA with data on the occurrence of contaminants suspected to be in drinking water, in order to determine if the EPA needs to introduce new regulatory standards to improve drinking water quality. Contact us for more information on this program.

REGULATED SUBSTANCES

SUBSTANCE (UNIT OF MEASURE)	YEAR SAMPLED	MCL [MRDL]	MCLG [MRDLG]	AMOUNT DETECTED	RANGE LOW-HIGH	VIOLATION	TYPICAL SOURCE
Alpha Emitters (pCi/L)	2017	15	0	4.8	3.1–4.8	No	Erosion of natural deposits
Barium (ppm)	2017	2	2	0.004	0.003–0.004	No	Discharge of drilling wastes; Discharge from metal refineries; Erosion of natural deposits
Combined Radium (pCi/L)	2017	5	0	3.1	1.5–3.1	No	Erosion of natural deposits
Fluoride (ppm)	2017	4	4	2.0	1.9–2.0	No	Erosion of natural deposits; Water additive that promotes strong teeth; Discharge from fertilizer and aluminum factories
Haloacetic Acids [HAAs] (ppb)	2017	60	NA	3	2–3	No	By-product of drinking water disinfection
TTHMs [Total Trihalomethanes] (ppb)	2017	80	NA	8.9	7.6–8.9	No	By-product of drinking water disinfection

Tap water samples were collected for lead and copper analyses from sample sites throughout the community.

SUBSTANCE (UNIT OF MEASURE)	YEAR SAMPLED	AL	MCLG	AMOUNT DETECTED (90TH%TILE)	SITES ABOVE AL/TOTAL SITES	VIOLATION	TYPICAL SOURCE
Copper (ppm)	2017	1.3	1.3	0.1540	0/30	No	Corrosion of household plumbing systems; Erosion of natural deposits
Lead (ppb)	2017	15	0	3.40	1/30	No	Corrosion of household plumbing systems; Erosion of natural deposits

SECONDARY SUBSTANCES

SUBSTANCE (UNIT OF MEASURE)	YEAR SAMPLED	SMCL	MCLG	AMOUNT DETECTED	RANGE LOW-HIGH	VIOLATION	TYPICAL SOURCE
Sulfate (ppm)	2017	250[1]	NA	550.00	460.00–550.00	No	Runoff/leaching from natural deposits; Industrial wastes

UNREGULATED SUBSTANCES

SUBSTANCE (UNIT OF MEASURE)	YEAR SAMPLED	AMOUNT DETECTED	RANGE LOW-HIGH	TYPICAL SOURCE
Nickel (ppb)	2017	2.5000	2.2000–2.5000	Alloy products
Sodium (ppm)	2017	16.00	12.00–16.00	Naturally occurring

[1] Secondary contaminants are regulated merely to protect the aesthetics of drinking water like taste, appearance, and odor. The U.S. EPA has not established adverse health effects associated with exceedances of SMCLs

Definitions

AL (Action Level): The concentration of a contaminant that, if exceeded, triggers treatment or other requirements that a water system must follow.

MCL (Maximum Contaminant Level): The highest level of a contaminant that is allowed in drinking water. MCLs are set as close to the MCLGs as feasible using the best available treatment technology.

MCLG (Maximum Contaminant Level Goal): The level of a contaminant in drinking water below which there is no known or expected risk to health. MCLGs allow for a margin of safety.

MRDL (Maximum Residual Disinfectant Level): The highest level of a disinfectant allowed in drinking water. There is convincing evidence that addition of a disinfectant is necessary for control of microbial contaminants.

MRDLG (Maximum Residual Disinfectant Level Goal): The level of a drinking water disinfectant below which there is no known or expected risk to health. MRDLGs do not reflect the benefits of the use of disinfectants to control microbial contaminants.

NA: Not applicable

pCi/L (picocuries per liter): A measure of radioactivity.

ppb (parts per billion): One part substance per billion parts water (or micrograms per liter).

ppm (parts per million): One part substance per million parts water (or milligrams per liter).

SMCL (Secondary Maximum Contaminant Level): SMCLs are established to regulate the aesthetics of drinking water like appearance, taste and odor.

Watershed Detail
USACE Parcel J

The Lower Fox River basin is located in northeastern Wisconsin and encompasses the following counties: Brown, Calumet, Outagamie and Winnebago. The 638 square mile (1,654 square kilometers) drainage basin is bordered by the Twin Door Kewaunee basin to the north and east, the Manitowoc River basin to the south and east, the Upper Fox River basin to the south, the Wolf River basin to the west and the Upper Green Bay basin to the north.

The Lower Fox River empties a drainage basin of 6,349 square miles (including drainage from the Wolf River and Upper Fox River basins), flowing northeast from the outlet of Lake Winnebago to the bay of Green Bay. The Fox River Valley is one of Wisconsin's most urbanized and industrialized areas. Most of these urban areas are close to the river and localized urban and industrial runoff has contributed to water quality problems. Urban nonpoint sources include runoff from existing urban areas including established commercial, industrial, freeways and residential land uses. The basin also contains many rich farmlands, which also contributes to the water quality problems in the area. Nonpoint sources include runoff from barnyards, areas winterspread with livestock manure, eroding agricultural lands and streambank erosion, cattle accessing the streams and other poor landuse practices.

Water quality studies reveal that most of the Lower Fox River basin streams and lower Green Bay suffer from excessive loadings of sediment, nutrients, bacteria and heavy metals resulting in: degraded aquatic habitat and an unbalanced fish community with low populations and limited diversity; sedimentation and excessive nutrient levels resulting in an advanced state of eutrophication; and high levels of toxic materials in bottom sediments and invertebrate organisms consumed by fish.

The Lower Fox River basin has been given statewide attention for improving and protecting water quality. Three watersheds: the East River, the Apple and Ashwaubenon Creeks and Duck Creek, have been selected as priority watersheds under the Wisconsin Nonpoint Source Water Pollution Abatement Program. The three remaining watersheds have been ranked "high" for possible selection, Plum Creek, Fox River/Appleton and Little Lake Butte Des Mort watersheds. The main focus of these projects is to reduce nutrient and sediment loadings to streams and rivers by 50% which is necessary for meaningful water quality improvements to occur.

Report — Map Unit Description

Outagamie County, Wisconsin

Uo—Udorthents

Map Unit Setting

National map unit symbol: g5rd
Elevation: 590 to 1,010 feet
Mean annual precipitation: 27 to 34 inches
Mean annual air temperature: 45 to 48 degrees F
Frost-free period: 130 to 150 days
Farmland classification: Not prime farmland

Map Unit Composition

Udorthents and similar soils: 100 percent

Estimates are based on observations, descriptions, and transects of the mapunit.

Description of Udorthents

Typical profile

A,C - 0 to 60 inches: variable

Properties and qualities

Slope: 0 to 6 percent
Depth to restrictive feature: More than 80 inches
Natural drainage class: Somewhat excessively drained
Capacity of the most limiting layer to transmit water (Ksat): Very low to high (0.00 to 5.95 in/hr)
Depth to water table: About 60 to 80 inches
Frequency of flooding: None
Frequency of ponding: None

Interpretive groups

Land capability classification (irrigated): None specified
Land capability classification (nonirrigated): 7e
Hydrologic Soil Group: A
Hydric soil rating: No

Setting

Landform: Ground moraines
Landform position (two-dimensional): Shoulder, backslope
Down-slope shape: Convex
Across-slope shape: Convex
Parent material: Silty loess over clayey till

Typical profile

A,E - 0 to 6 inches: silty clay loam
Bt - 6 to 27 inches: clay
C - 27 to 60 inches: silty clay

Properties and qualities

Slope: 20 to 45 percent
Depth to restrictive feature: More than 80 inches
Natural drainage class: Well drained
Capacity of the most limiting layer to transmit water (Ksat): Very low to moderately high (0.00 to 0.57 in/hr)
Depth to water table: About 60 to 80 inches
Frequency of flooding: None
Frequency of ponding: None
Calcium carbonate, maximum in profile: 35 percent
Available water storage in profile: Moderate (about 8.5 inches)

Interpretive groups

Land capability classification (irrigated): None specified
Land capability classification (nonirrigated): 7e
Hydrologic Soil Group: C
Forage suitability group: Mod AWC, adequately drained with limitations (G095AY006WI)
Hydric soil rating: No

Minor Components

Slope is greater than 45%

Percent of map unit:
Hydric soil rating: No

Slope is less than 20%

Percent of map unit:
Hydric soil rating: No

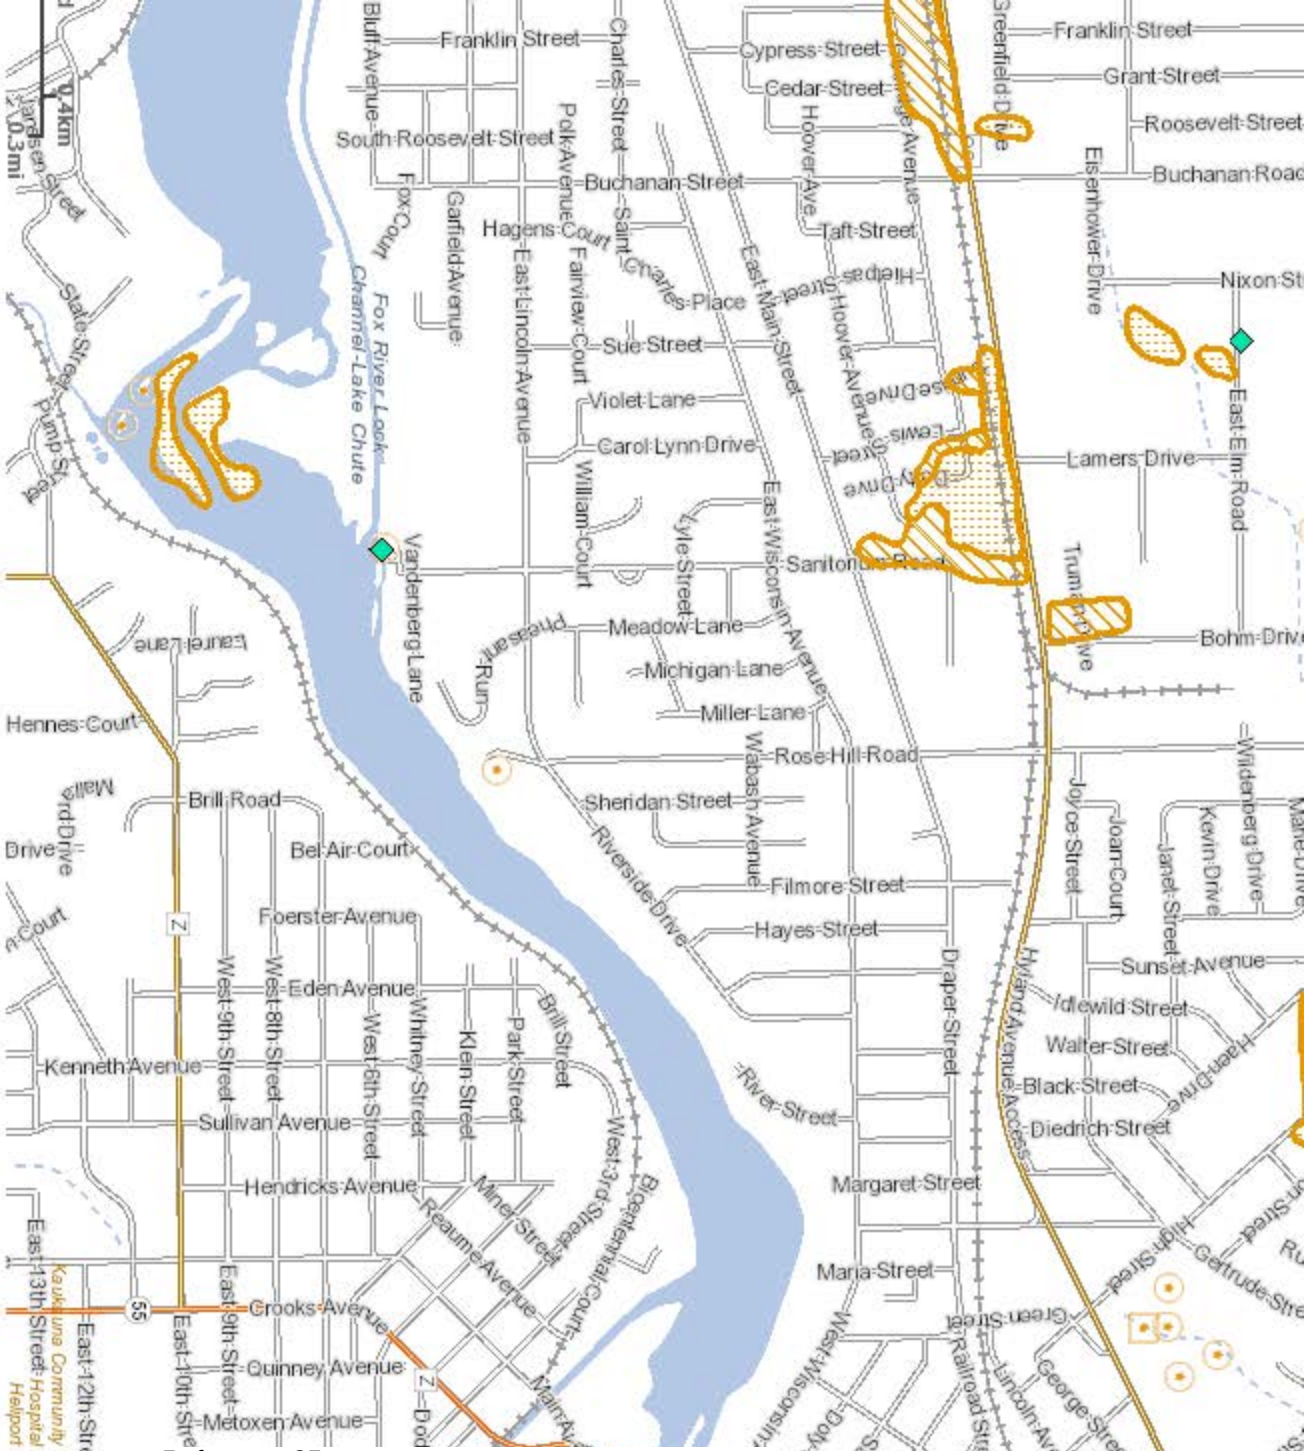
Find the advice for eating fish from Wisconsin waters

County	
Advisory Area	

Advice for eating fish from the area you selected:

County: Brown, Outagamie, Winnebago
Advisory Area: FOX RIVER FROM LITTLE LAKE BUTTE DES MORTS TO THE DAM AT DEPERE
Includes: FOX RIVER, FOX RIVER LOCK CHANNEL-KAUKAUNA, LITTLE LAKE BUTTE DES MORTS

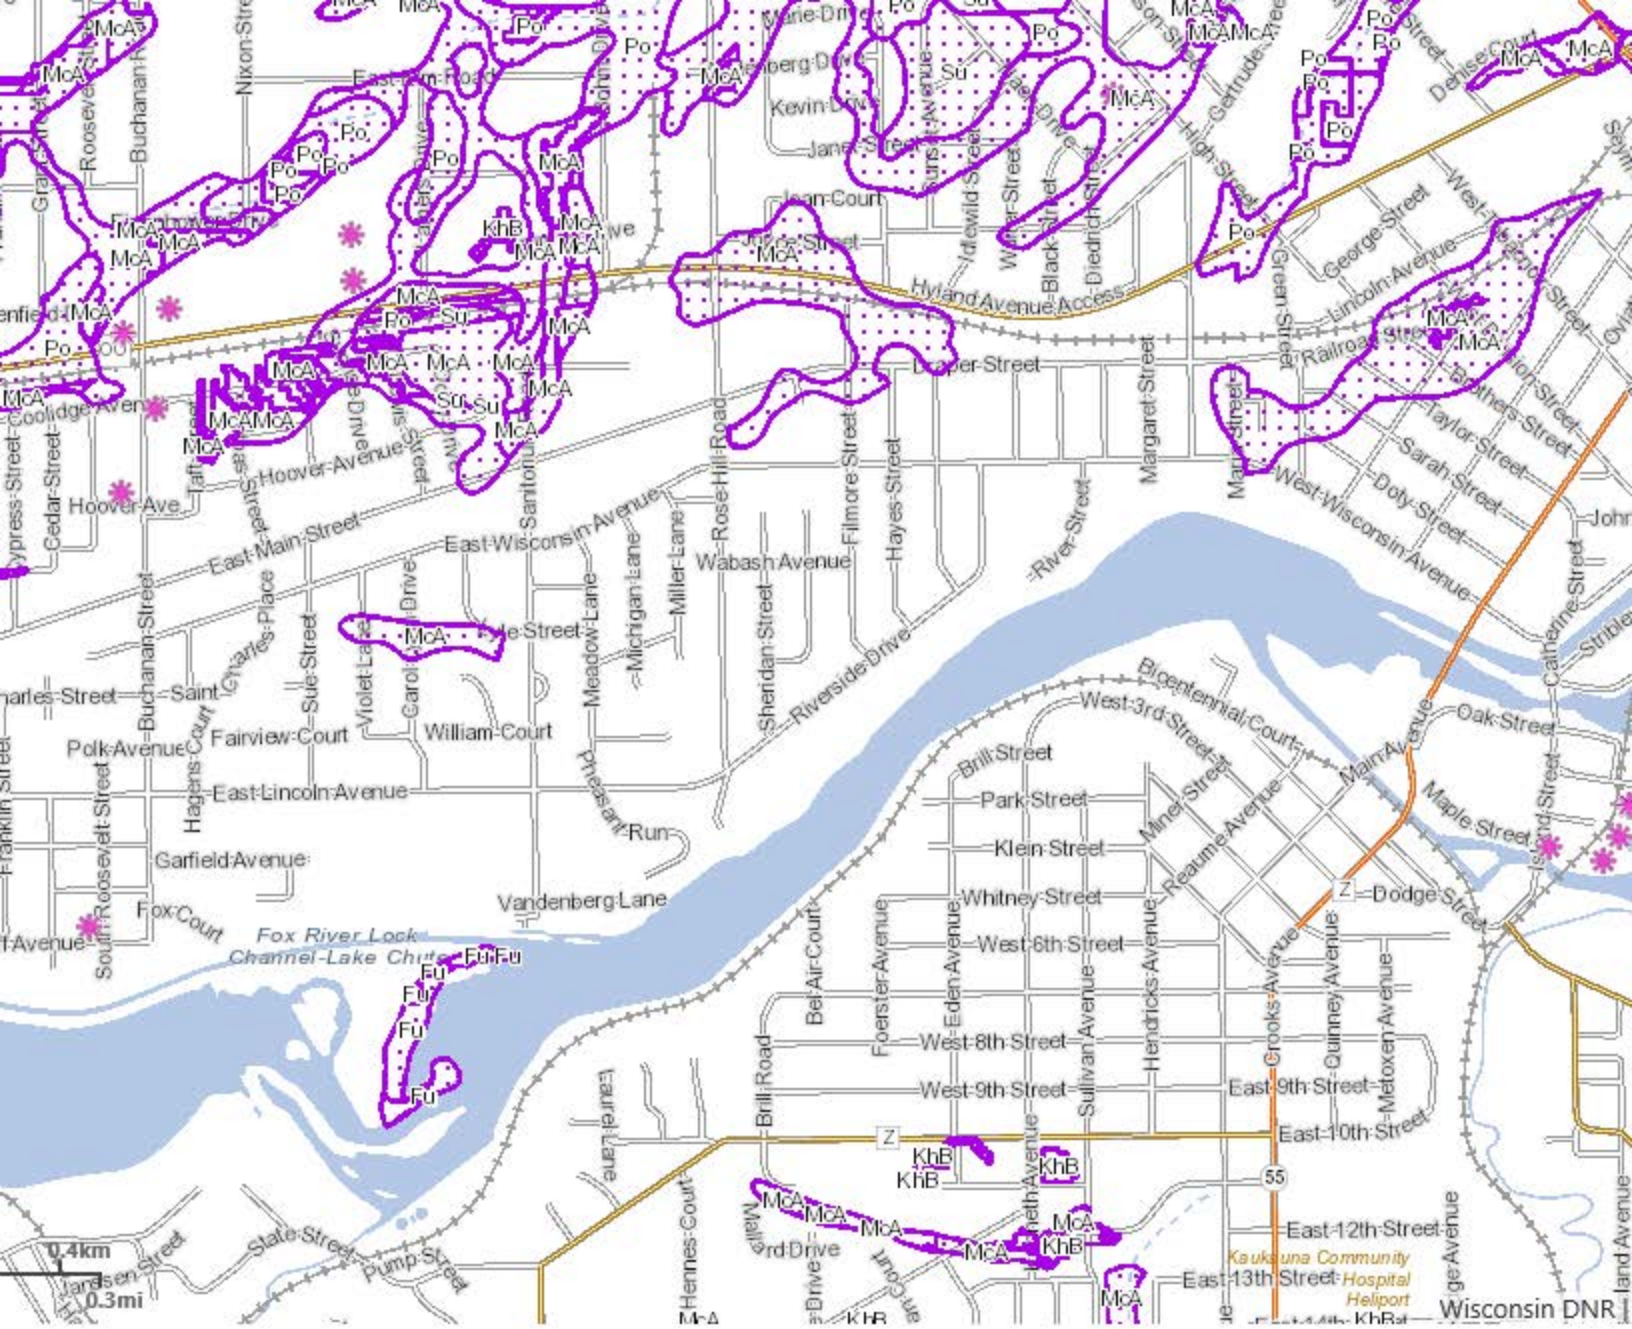
Women up to age 50 (child bearing age) and children (under age 15) may safely eat:



1 Meal Per Week	bluegill and sunfish, bullheads, crappies, inland trout
and	
1 Meal Per Month	channel catfish, pike, walleye, white bass, white perch, yellow perch, all other species and sizes
6 Meals Per Year	carp less than 28"
Do Not Eat	carp larger than 28", muskies

All men (15 and older) and older women (50 and older) may safely eat:

Unrestricted	bluegill and sunfish, bullheads, crappies, inland trout
1 Meal Per Week	pike, all other species and sizes
and	
1 Meal Per Month	channel catfish, muskies, walleye, white bass, white perch, yellow perch
6 Meals Per Year	carp less than 28"
Do Not Eat	carp larger than 28"



The above advice is due to the following pollutants:MERCURY, PCB
Date of Query:August 26 2019

Whether you are in a high risk zone or not, you may need flood insurance (https://www.fema.gov/national-flood-insurance-program) because most homeowners insurance doesn't cover flood damage. If you live in an area with low or moderate flood risk, you are 5 times more likely to experience flood than a fire in your home over the next 30 years. For many, a National Flood Insurance Program's flood insurance policy could cost less than $400 per year. Call your insurance agent today and protect what you've built.

Learn more about steps you can take (https://www.fema.gov/what-mitigation) to reduce flood risk damage.

Bald Eagle

Bald eagles are no longer protected under the federal Endangered Species Act and Section 7 consultation with the U.S. Fish and Wildlife Service is no longer necessary. However, the bald eagle remains protected under the Bald and Golden Eagle Protection Act.

Information about Bald Eagles

Information about Eagle Permits and the Bald and Golden Eagle Protection Act

Gray Wolf

Due to a Federal court decision, wolves in the western Great Lakes area (including Michigan, Minnesota, and Wisconsin) were relisted under the Endangered Species Act, effective December 19, 2014.

Revised Jan. 10, 2018

Species	Status	Counties	Habitat
Mammals			
Canada lynx (*Lynx canadensis*)	Threatened	Ashland, Bayfield, Burnett, Douglas, Florence, Forest, Iron, Marinette, Oneida, Price, Sawyer, Vilas, Washburn	While no resident populations are known from Wisconsin, the species occasionally occurs in northern forested areas, and counties listed are those with the highest

			occur on protected conservation lands.
Northern monkshood *(Aconitum noveborancense)*	Threatened	Grant, Monroe, Richland, Sauk, Vernon	North facing slopes
Pitcher's thistle *(Cirsium pitcheri)*	Threatened	Door, Manitowoc, Sheboygan	Stabilized dunes and blowouts
Prairie bush-clover *(Lespedeza leptostachya)*	Threatened	Columbia, Dane, Grant, Green, Iowa, Lafayette, Pepin, Pierce, Rock, St. Croix, Sauk	Dry to mesic prairies with gravelly soil areas

****Whooping Crane -** On June 26, 2001, a nonessential experimental population of the whooping crane was designated in a 20-state area of the eastern United States. The first release of birds occurred in Wisconsin in 2001, and the counties listed are those where the species has been observed to date. It is unknown at this time which counties the species will occupy in the future, as the birds mature and begin to exhibit territorial behavior. For purposes of section 7 consultation, this species is considered as a proposed species, except where it occurs within the National Wildlife Refuge System or the National Park System, where it is treated as a threatened species.

231 S. LaSalle Street STE 1500
Chicago IL 60604

Subject: Reported Contamination at USACE – Parcel J (Kaukauna Power Canal), End of Bicentennial Ct, Kaukauna, WI
DNR BRRTS Activity # 02-45-548419

Dear Mr. O'Neil:

In February 2004 the Department of Natural Resources ("department") issued a Responsible Party Letter to the United States Army Corps of Engineers (USACE) for all releases discovered at USACE properties along the Fox River, identified in the 2003 Altech Phase II report, including parcel J (Kaukauna Power Canal). Parcel J had lead detected soil which was reported as part of the 2003 Phase II report. In November 2007 USACE submitted a case closure request for the Parcel J (Kaukauna Power Canal) Site (BRRTS #: 02-45-548419). Closure was denied March 2008, at the time the department recommended remedial action to address lead impacts in soil and evaluating if groundwater monitoring would be necessary following the remedial action. Since that letter was issued no additional action has been performed at the site by the USACE. In 2020, the department will be completing a Superfund Site Assessment at Parcel J.

Based on the information available to the DNR regarding ownership of this property, we believe that the USACE remains the landowner in possession of the above referenced property. As the landowner you are in possession or control of the hazardous substance discharge or other environmental pollution (hereafter referred to as "contamination") at the above-described site, and, as such, you are responsible under Wisconsin Statutes ("Wis. Stats.") ch. 292 for the investigation and cleanup of the contamination at the site. The term "site" includes the property where the contamination occurred and any other property it has migrated to, pursuant to Wisconsin Administrative Code ("Wis. Admin. Code") § NR 700.03(56).

This letter explains how to initiate the investigation and cleanup of contamination of the site, and how to access further information and assistance from the department. The longer contamination is left in the environment, the farther it can spread and the more it may cost to clean up. Quick action may lessen damage to your property and neighboring properties and reduce your costs in investigating and cleaning up the contamination.

Legal Responsibilities:

Persons meeting the definition of "responsible party" under § NR 700.03(51) must follow applicable law to address the discharge of a hazardous substance to the environment or other environmental pollution. Wisconsin Statutes ("Wis. Stats.") ch. 292 and Wis. Admin. Code chs. NR 700 through NR 754 provide

specific requirements for undertaking appropriate response actions to address contamination, including requirements for emergency and interim actions, public information, site investigations, remedy selection, design and operation of remedial action systems, and case closure.

General Recommendations for Responsible Parties:

The department recommends that you:

1. Hire a Qualified Environmental Consultant

To ensure response actions you plan to undertake comply with Wisconsin law, you should hire an environmental consultant within **30 days,** by September 11, 2020, to meet the regulatory deadlines listed below. A delay in hiring an environmental consultant could result in you missing key submittal deadlines.

Hiring a consulting firm with staff that have the appropriate State of Wisconsin qualifications to supervise and certify the submittals is a critical component and necessary to meet your requirements. Further, an environmental consultant should be knowledgeable of Wisconsin's technical procedures and laws, and be able to answer questions regarding cleanup requirements. Required qualifications for environmental consultants are specified in Wis. Admin. Code ch. NR 712. Program guidance is available, see *Wis. Admin. Code ch. NR 712 Qualifications and Certifications, RR-081*.

2. Properly Submit Reports on Time with Required Information Included

Wisconsin law includes timeframes for submitting technical documents and conducting work, as well as specifications for what should be included in those submittals. This letter provides a general overview of the timeframes and first steps to take for site investigation and cleanup. For an overview of timing requirements, please refer to *NR 700 Process and Timeline Overview, RR-967*, *enclosed.*

The department developed the publication *Guidance for Electronic Submittals for the Remediation and Redevelopment Program, RR-690,* to assist responsible parties and consultants in properly submitting documents. Wis. Admin. Code § NR 700.11(3g), and other specific provisions within Wis. Admin. Code ch. NR 700, outline the requirements for submittals, including electronic submittals. Consultants and representatives of responsible parties are required to submit one paper copy and one electronic copy of submittals, including case closure documents. The electronic version must be an exact duplicate of the paper version. Failure to submit both a paper copy and electronic copy delays acceptance of your submittals.

3. Consider the Benefits of a Fee-based Technical Review of your Submittals

In-depth department review of technical reports and submittals is available for a fee. The Remediation and Redevelopment (RR) Program project managers are available throughout the process to answer general questions and provide general input as the site moves toward closure. However, if you want a formal written response from the department, a meeting or both on a specific submittal, a review fee will be required in accordance with Wis. Admin. Code ch. NR 749. **Obtaining technical assistance from department project managers throughout the process is an effective way to prevent problems and delays at the end of the process when case closure is requested.** Forms, a fee schedule, and further information on technical assistance is available at dnr.wi.gov and searching "brownfield fees".

Required Steps to Take and Documents to Submit:

The steps listed below serve as a general overview only — all mandatory steps and submittals specified in state law must be met before the department can grant "case closure", which is a determination by the department that no further cleanup is necessary at a site, as defined in Wis. Admin. Code § NR 700.03(3m).

1. **Scoping and Work Plan Submittal – NR 716.07 and 716.09**: The law requires that you appropriately scope out your site investigation and submit a work plan within **60 days of this notification,** by October 10, 2020, for completing a site investigation. The work plan must comply with the requirements in Wis. Admin. Code, chs. NR 700 through NR 754. For additional assistance, the department has extensive guidance on its web page at dnr.wi.gov and search "brownfield publications".

   Prior to and during a site investigation, you must evaluate whether any interim actions are needed to contain or stabilize a hazardous substance discharge or environmental pollution, pursuant to Wis. Admin. Code § NR 708.11. If you undertake an interim action (*e.g.*, free product removal), you must submit documentation of the action per Wis. Admin. Code § NR 708.15.

   As you develop the site investigation work plan, you must include an assessment of the vapor intrusion pathway. Wis. Admin. Code § NR 716.11(5) outlines the requirements for when to evaluate for the presence of vapors in the sub-surface and in indoor air. The results and conclusions from the vapor assessment must be included in the Wis. Admin. Code § NR 716.15 site investigation report whether or not you elected to take vapor samples. *Addressing Vapor Intrusion at Remediation & Redevelopment Sites in Wisconsin, RR-800,* is available to help responsible parties and their consultants comply with these requirements.

2. **Field Investigation – NR 716.11**: Following submission of the work plan, the site investigation must be started within the timeframe provided under law. The timeframe varies depending on whether you are requesting the department's fee-based review of the work plan. If you do not request a fee-based review of the work plan, you must initiate the field investigation within 90 days of submitting the work plan, and you may proceed with the field investigation upon department notification to proceed; however, if the department has not responded within 30 days, from submittal of the work plan, you may then proceed with the field investigation. If a fee and request for department review of the work plan is submitted, the field investigation must begin within 60 days after receiving department approval.

3. **Sample Results Notification Requirements – NR 716.14**: You must report sampling results to the department, owners, occupants, and various other parties within 10 business days after receiving the sampling results, unless a different timeframe is approved by the department, in accordance with Wis. Admin. Code § NR 716.14.

4. **Site Investigation Report – NR 716.15**: Within 60 days after completion of the field investigation and receipt of the laboratory data, the law requires you to submit a Site Investigation Report (SIR) to the department. As part of the SIR or in the Remedial Actions Options Report (RAOR), if there is soil contamination, the responsible party shall identify the current land use (*i.e.*, industrial or non-industrial) and zoning for the site or facility in accordance with Wis. Admin. Code § NR 720.05(5).

Also, as part of the SIR or in the RAOR, you must include any interim action report that may be required under Wis. Admin. Code § NR 708.15.

5. **Remedial Actions Options Report – NR 722**: Within 60 days after submitting the SIR, the law requires you to submit a RAOR. The selected remedy in the RAOR should include an evaluation of green and sustainable remediation criteria, as appropriate, as required by Wis. Admin. Code § NR 722.09(2m). This may be submitted as part of a broader SIR.

6. **Remedial and Interim Action Design, Implementation, Operation, Maintenance and Monitoring Reports – NR 724**: Unless otherwise directed by the department, the responsible party shall submit all plans and reports required in Wis. Admin. Code ch. NR 724.

7. **Notification of Residual Contamination or Continuing Obligations – NR 725**: In situations where notification is required, the responsible party must provide submittal(s) that confirms that continuing obligations have been identified and affected property owners have been notified by the responsible parties 30 days prior to case closure, as required by Wis. Admin. Code ch. NR 725.

8. **Semi-annual Reporting -- NR 700.11**: Wis. Admin. Code § NR 700.11(1)(a) requires responsible parties to submit semi-annual site progress reports to the department until final case closure is granted. The reports summarize the work completed over six months and additional work planned to adequately complete the response action at the site. Consultants may submit these reports on behalf of responsible parties. These reports are due in January and July of each year. Please refer to department publication *NR 700 Semi-Annual Site Progress Report, RR-082*, for more information.

Submittals required under Wis. Admin. Code chs. NR 700 - 726

These documents, as applicable, must be submitted to the department prior to the responsible party requesting case closure, unless otherwise directed by the department:

- Ch. NR 708 reports and documentation for any immediate or interim actions.
- Ch. NR 712 professional certifications and signatures are included with applicable submittals.
- Ch. NR 716 work plan(s) and site investigation report.
- Ch. NR 722 remedial action options report (exception is for Dry Cleaners Environmental Response Fund sites), with the selected remedial action identified.
- Ch. NR 724 design, construction documentation, operation, maintenance and monitoring plans and reports, including vapor mitigation commissioning.
- Ch. NR 725 submittal(s) that confirms that continuing obligations have been identified and affected property owners have been notified by the responsible parties 30 days prior to case closure.
- If requesting case closure, the Ch. NR 726 case closure form and documentation substantiating compliance with the NR 700 rule series.
- Ch. NR 749 fees have been paid, as applicable, including closure and database fees.
- Ch. NR 700 semi-annual site progress reports starting six months after notification.

Additional Information:

The department tracks information on all cleanup sites in a department database available at dnr.wi.gov and search "BOTW". The Bureau for Remediation and Redevelopment Tracking System (BRRTS) identification number for this site is listed at the top of this letter. You may view information related to your site on this database at any time.

All correspondence regarding this site should be directed to:

Sarah Krueger
Remediation and Redevelopment Program
Wisconsin Department of Natural Resources
2984 Shawano Avenue
Green Bay WI 54313-6727
sarah.krueger@wisconsin.gov

As previously noted, you are required to submit one paper copy and one electronic copy of plans and reports. To speed up processing, your correspondence should reference the BRRTS and Facility Identification (FID) numbers (if assigned) listed at the top of this letter.

Please visit the department's Remediation and Redevelopment Program website at dnr.wi.gov and search "Brownfields", for information on selecting a consultant, seeking financial assistance, and understanding the investigation and cleanup process. Information regarding review fees, liability clarification letters, post-cleanup liability and more is also available.

If you have questions, please call Sarah Krueger at 920-662-5443 for more information.

Thank you for your cooperation.

Sincerely,

Denise D. Danelski

Arsenic in Drinking Water

Drinking Water Wells tested with Arsenic Levels Greater than 10 ppb.

Arsenic has been detected in every county in the State of Wisconsin. The shaded counties on the map represent areas with water wells that had arsenic levels exceeding the arsenic drinking water standard of 10 parts per billion (ppb). Serious problems with arsenic are however concentrated in specific regions within these counties.

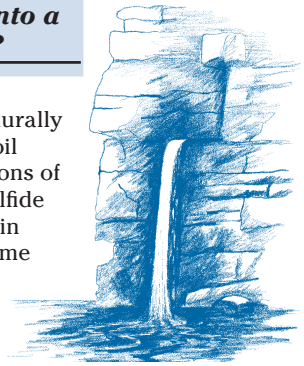
Wisconsin Department of Natural Resources
Bureau of Drinking Water & Groundwater

What is arsenic?

Arsenic is an element that occurs naturally in soil and bedrock formations. Traces of arsenic are also found in groundwater, lakes, rivers and ocean water. Foods like fruits, vegetables, and seafood can also contain arsenic. Some fruits and vegetables absorb traces of arsenic from the soil they grow in. Ocean fish and seafoods naturally have high levels of an organic non-toxic form of arsenic.

High levels of inorganic arsenic, the most toxic form, have been found in over 1,200 private drinking water wells in Wisconsin. The map on the cover shows counties where wells have been tested and found to contain arsenic above 10 ppb.

How can I be exposed to arsenic?



Since arsenic is a natural part of our environment, everyone is exposed to small amounts. The major source of arsenic exposure is drinking water that contains elevated levels of arsenic. Other sources of arsenic exposure include:

- foods containing traces of arsenic
- smoke from wood, coal, tobacco products
- dust from some industrial processes
- pesticides
- anti-parasitic veterinary medicines
- folk remedies
- some treated lumber

People who are exposed to arsenic over a period of years can experience a variety of health problems. Arsenic can be easily absorbed into the human system by drinking contaminated water or by breathing airborne particulates. In most cases, it is safe to use water that contains arsenic to bathe and for household chores. Arsenic is not easily absorbed through the skin and does not evaporate from the water into the air.

How does arsenic get into a drinking water supply?

Most of the arsenic found in Wisconsin groundwater is naturally occurring, deposited in the soil and bedrock layers over millions of years. Arsenic is tied up in sulfide minerals, which are common in bedrock formations and in some glacial deposits. Arsenic can be released from soil and rock into the groundwater and drawn into wells.

Scientists who have studied this problem believe arsenic is being released into groundwater at elevated levels in the Outagamie, Winnebago and Brown County area at least partly because people are now using more water than ever before due to rapid suburban development. During the past ten years, about 10,000 new wells have been constructed in this area. Water quality problems have increased as more new wells are being drilled and demands on groundwater continue to increase.

Studies have shown that increased water demands have lowered the water table in this area. This has allowed oxygen to get into the bedrock aquifers, creating chemical reactions that release arsenic into the water. In other areas of the State, different types of reactions can release arsenic that moved into Wisconsin, in the geologic past, from other geographic sources. Scientists are studying these and other possible factors to determine the best ways to avoid arsenic problems. The Department of Natural Resources staff continue to study arsenic contamination problems throughout the State to determine its geographical extent and severity.

How can arsenic affect my health?

Consumption of arsenic-contaminated water has been associated with the following possible health effects:

- Skin cancer
- Internal cancers (bladder, prostate, lung and other sites)
- Thick, rough skin on hands and feet
- Unusual skin pigmentation (dappling of dark brown or white splotches)
- Numbness in the hands and feet
- Circulatory disorders
- Tremors
- Stomach pain, nausea, diarrhea
- Diabetes
- Depression

Arsenic contamination of drinking water is a serious health concern. If you think you or someone in your family has symptoms from arsenic exposure talk to your doctor and have your water tested for arsenic.

How can I find out if my water is contaminated with arsenic?

You cannot smell, taste or see arsenic in your drinking water. The only way to know if your water contains arsenic is to have a water sample from your private well tested by a certified laboratory. A list of certified labs is available at **dnr.wi.gov**, Search: Arsenic

If you use water from a public water system, check the water system's Consumer Confidence Report (CCR). Public water systems distribute copies of their CCR to system users each summer. The section titled "Where can I get more information", found in this brochure contains instructions to help you find your CCR on the website.

If the arsenic level in your water is above the drinking water standard of 10 ppb, stop drinking your water. Obtain water from a known safe source for drinking and preparation of beverages or for foods like baby formula, soup, and coffee. Unless your arsenic level exceeds 100 ppb, it is safe to bathe in the water and use it for household purposes. If arsenic levels exceed 100 ppb, you should consult your local or County health department.

If the arsenic level in your water is just under 10 ppb and you consume 2 liters (about 68 ounces) or more of drinking water from this source per day, you may wish to try to reduce your exposure to arsenic. Contact your health care provider or local health department to determine your specific needs.

New well construction or reconstructions have been successful at reducing the arsenic concentrations in water supply systems. For levels of arsenic contamination exceeding 50 ppb, Department of Natural Resources *Well Compensation Program* funds may be available for replacement water systems for income eligible private well owners or lessees.

Everyone should have a sample of their water tested for arsenic at least once every five years, whenever a change in the color of your water or staining of fixtures is observed, or if water levels in your well have changed. If you are in the *"Special Well Casing Depth Area"* (Outagamie and Winnebago Counties) or an area where arsenic has been detected, the Department of Natural Resources recommends you retest your well water each year, regardless of previous test results because concentrations of arsenic can change over time. (See the map on the front of this brochure for counties in Wisconsin where arsenic levels are known to have exceeded 10ppb.) In a small percentage of wells that produce water with high levels of arsenic, the water is very acid and can corrode plumbing pipes and fixtures. Conversely, if you have corrosive water, i.e. your pipes and fixtures are corroding, there is a greater chance you have an arsenic problem.

Can water treatment systems remove arsenic?

Yes, special treatment systems can remove arsenic from well water. However, be aware that common treatment systems like water softeners, carbon filters and sediment filters do not adequately remove arsenic from water. Do not purchase a treatment system unless you have first checked with the Department of Safety and Professional Services (DSPS) approved treatment device list. (website below under Department of Safety and Professional Services)

There are two types of treatment systems currently available for arsenic removal. These treatment systems are "point-of-use" and "point-of-entry" systems. Point-of-use systems generally only treat one faucet that is used for drinking and cooking. Point-of-entry systems treat all the water entering the house. New treatment technologies that will reduce arsenic in your water supply are presently being developed. Once you have determined which treatment option is correct for your water supply, it is recommended that you use a licensed plumber for installation. After installation, follow the maintenance instructions provided by the manufacturer very closely and verify with sampling to make sure the system continues to operate as a viable arsenic reduction water treatment system.

Drilling a new well may be necessary for extremely high levels of arsenic. Talk to your well driller or your drinking water & groundwater specialist at your DNR regional office about special well construction guidelines.

Where can I get more information?

Health Departments

The Department of Health & Family Services has more information on the health effects of arsenic exposure at **dhs.wi.gov**, Search: Arsenic

State Department of Health Services, Division of Public Health..... 608-266-7480

Brown Co. Health Dept. 920-448-6400

Outagamie Co. Health Dept. 920-832-5100

Winnebago Co. Health Dept..... 920-232-3000

Department of Safety and Professional Services

The Department of Safety and Professional Services maintains a list of treatment devices approved for removing arsenic at **dsps.wi.gov/php/sb-ppalopp/contam_alpha_list.php**

Department of Natural Resources

The DNR maintains the following pages with information relating to labs, water quality and arsenic research.

Wisconsin's Arsenic Information Page

Visit the DNR Web site for arsenic information related to well drilling, water treatment options, recent news articles, research papers and more! Go to **dnr.wi.gov**, Search: Arsenic

Certified Laboratories

A list of certified labs is available on the Arsenic webpage mentioned above or check your local yellow pages and ask if they are state certified to test for arsenic.

Consumer Confidence Reports

Your local water supplier prints a special report on the quality of your public water system's drinking water. Contact your local water supplier or find your system's latest report on the Web! Go to **dnr.wi.gov**, Search: Consumer Confidence Report. A query, or search, can then be made by city or individual system.

KEEP THIS LEGAL DOCUMENT WITH YOUR PROPERTY RECORDS

SUBJECT: Case Closure with Continuing Obligations
Fox Shores Apartments, 400 Fox Shores Drive, Kaukauna, WI 54130
BRRTS #: 02-45-582746, FID #: 445207290

Dear Mr. Vandeyacht and Mr. Rankin:

The Wisconsin Department of Natural Resources (DNR) is pleased to inform you that the Fox Shores Apartments case identified above met the requirements of Wisconsin Administrative (Wis. Admin.) Code chs. NR 700 to 799 for case closure with continuing obligations (COs). COs are legal requirements to address potential exposure to remaining contamination. No further investigation or remediation is required at this time for the reported hazardous substance discharge and/or environmental pollution.

However, you, future property owners and occupants of the property must comply with the COs as explained in this letter, which may include maintaining certain features and notifying the DNR and obtaining approval before taking specific actions. You must provide this letter and all enclosures to anyone who purchases, rents or leases this property from you. You may be required to make a real estate condition report disclosure under Wis. Stat. ch. 709.

This case closure decision is issued under Wis. Admin. Code chs. NR 700 to 799 and is based on information received by the DNR to date. The DNR reviewed the case closure request for compliance with state laws and standards and determined the case closure request met the notification requirements of Wis. Admin. Code ch. NR 725, the response action goals of Wis. Admin. Code § NR 726.05(4), the case closure criteria of Wis. Admin. Code §§ NR 726.05, 726.09, and 726.11, and Wis. Admin. Code ch. NR 140.

The Fox Shores Apartments site was investigated for a discharge of hazardous substances and/or environmental pollution from historic soil fill and historic property use. Case closure is granted for the volatile organic compounds (VOCs), polycyclic aromatic hydrocarbons (PAHs), and Resource Conservation Recovery Act metals (RCRA metals) sampled during the site investigation, as documented in the case file. The site investigation and/or remedial action addressed soil, and groundwater. The remedial action consisted of a one-foot excavation of

PRINTED ON RECYCLED PAPER

landscaped areas with caping consisting of an engineered geotextile fabric underlying 12-inches of clean fill and/or topsoil. Excavated soils were placed in one of four designated fill locations creating landscape berms capped with engineered geotextile fabric underlying 12-inches of clean fil and/or topsoil. PAH, RCRA metals, and VOC contamination remain in soil and/or groundwater, across the site.

The case closure decision and COs required were based on the current use of the site for residential purposes. The site is currently zoned Commercial Core. Based on the land use and zoning, the site meets the non-industrial land use classification under Wis. Admin. Code § NR 720.05(5) for application of residual contaminant levels in soil.

SUMMARY OF CONTINUING OBLIGATIONS

COs are applied at the following location:

ADDRESS (City of Kaukauna, WI)	COS APPLIED	DATE OF MAINTENANCE PLAN(S)
400 Fox Shores Drive (Source Property)	• Residual Soil Contamination • Cover for Soil (Maintenance Required) • Residual Groundwater Contamination	Not applicable January 24, 2022 Not applicable

CLOSURE CONDITIONS

Closure conditions are legally required conditions which include both COs and other requirements for case closure (Wis. Stat. § 292.12(2)). Under Wis. Stat. § 292.12(5), you, any subsequent property owners and occupants of the property must comply with the closure conditions as explained in this letter. The property owner must notify occupants for any condition specified in this letter under Wis. Admin. Code §§ NR 726.15(1)(b) and NR 727.05(2). If an occupant is responsible for maintenance of any closure condition specified in this letter, you and any subsequent property owner must include the condition in the lease agreement under Wis. Admin. Code § NR 727.05(3) and provide the maintenance plan to any occupant that is responsible.

DNR staff may conduct periodic pre-arranged inspections to ensure that the conditions included in this letter and the maintenance plan dated, January 24, 2022, are met (Wis. Stat. § 292.11(8)). If these requirements are not followed, the DNR may take enforcement action under Wis. Stat. ch. 292 to ensure compliance with the closure conditions.

SOIL

Continuing Obligations to Address Soil Contamination

Residual Soil Contamination (Wis. Admin. Code chs. NR 718, NR 500 to 599, and § NR 726.15(2)(b) and Wis. Stat. ch. 289)

Soil contamination remains across the site as indicated on the enclosed map (Figure B.2.b., Residual Soil Contamination, dated April 24, 2020). If soil in the location(s) shown on the map is excavated in the future, the property owner or right of way holder at the time of excavation must sample and analyze the excavated soil. If sampling confirms that contamination is present, the property owner or right of way holder at the time of excavation will need to determine if the material is considered solid waste and ensure that any storage, treatment

or disposal complies with applicable standards and rules. Contaminated soil may be managed under Wis. Admin. Code ch. NR 718 with prior DNR approval.

In addition, all current and future property owners, occupants and right of way holders need to be aware that excavation of the contaminated soil may pose an inhalation and direct contact hazard; special precautions may be needed to prevent a threat to human health.

Cover for Soil (Maintenance Required) (Wis. Stat. § 292.12(2)(a), Wis. Admin. Code §§ NR 724.13(1) and (2), NR 726.15(2)(d) and/or (e), NR 727.07(1))
The cover consists of either building, gravel, concrete, asphalt, or landscape cap across the entire site, as shown on the enclosed map (Figure D.2, Cap Location Map, dated February 5, 2021) shall be maintained in compliance with the enclosed maintenance plan, dated January 24, 2022. The purpose of the cover is to prevent direct contact with residual soil contamination that might otherwise pose a threat to human health.

To modify or replace a cover, the property owner must submit a request to the DNR under Wis. Admin. Code ch. NR 727. The DNR approval must be obtained before implementation. The replacement or modified cover must be a structure of similar permeability or be protective of the revised use of the property until contaminant levels no longer exceed Wis. Admin. Code ch. NR 720 direct contact residual contaminant levels (RCLs).

GROUNDWATER

Continuing Obligations to Address Groundwater Contamination and/or Monitoring Wells

Residual Groundwater Contamination (Wis. Admin. Code ch. NR 140 and § NR 812.09(4)(w))
Groundwater contamination which equals or exceeds the enforcement standards for PAHs is present in temporary wells TW17 and B3 on the western portion of the site, as shown on the enclosed map (Figure B.3.b., Groundwater Isoconcentration, dated May 22, 2020). To construct a new well or reconstruct an existing well, the property owner must obtain prior DNR approval. Additional casing may be necessary to prevent contamination of the well.

OTHER CLOSURE REQUIREMENTS

Maintenance Plan and Inspection Log (Wis. Admin. Code §§ NR 726.11(2), NR 726.15(1)(d), NR 727.05(1)(b)3., Wis. Admin. Code § NR 716.14(2) for monitoring wells)
The property owner is required to comply with the enclosed maintenance plan dated January 24, 2022, for the cover, to conduct inspections annually, and to use the inspection log (DNR Form 4400-305) to document the required inspections. The maintenance plan and inspection log are to be kept up-to-date and on-site, or at the address of the property owner. The property owner shall submit the inspection log to the DNR only upon request, using the RR Program Submittal Portal. See the DNR Notification and Approval Requirements section below for more information on how to access the Submittal Portal.

The limitations on activities are identified in the enclosed maintenance plan(s). The following activities are prohibited on any portion of this property where the cover is required, without prior DNR approval.

- Removal of the existing barrier;
- Replacement with another barrier;
- Excavating or grading of the land surface;
- Filling on capped or paved areas;
- Plowing for agricultural cultivation;
- Construction or placement of a building or other structure; and
- Changing the use or occupancy of the property to single-family residential.

Pre-Approval Required for Well Construction (Wis. Admin. Code § NR 812.09(4)(w))
DNR approval is required before well construction or reconstruction for all sites identified as having residual contamination and/or COs. This requirement applies to private drinking water wells and high capacity wells. To obtain approval, the property owner is required to complete and submit Form 3300-254, Continuing Obligations/Residual Contamination Well Approval Application, to the DNR Drinking and Groundwater program's regional water supply specialist. A well driller can help complete this form. The form can be obtained online at dnr.wi.gov, search "3300-254." Additional casing may be necessary to help prevent contamination of the well.

General Wastewater Permits for Construction-related Dewatering Activities (Wis. Admin. Code ch. NR 200)
The DNR's Water Quality Program regulates point source discharges of contaminated water, including discharges to surface waters, storm sewers, pits, or to the ground surface. This includes discharges from construction-related dewatering activities, including utility work and building construction.

If the property owner or any other person plans to conduct such activities, that person must contact the Water Quality Program and, if necessary, apply for the required discharge permit. If residual soil or groundwater contamination is likely to affect water collected in a pit/trench that requires dewatering, a general permit for discharge of *Contaminated Groundwater from Remedial Action Operations* may be needed. If water collecting in a pit/trench that requires dewatering is expected to be free of pollutants other than suspended solids, oil and grease, a general permit for pit/trench *Dewatering Operations* may be needed. Additional information can be obtained by visiting the DNR website at "dnr.wi.gov," search "wastewater general permits."

DNR NOTIFICATION AND APPROVAL REQUIREMENTS

Certain activities are limited at closed sites to maintain protectiveness to human health and the environment. The property owner is required to notify the DNR at least 45 days before and obtain approval from the DNR prior to taking the following actions (Wis. Admin. Code §§ NR 727.07, NR 726.15 (2), Wis. Stat. § 292.12(6)).

- Before removing a cover or any portion of a cover

The DNR may require additional investigation and/or cleanup actions if necessary, to be protective of human health and the environment. The case may be reopened under Wis. Admin. Code § NR 727.13 if additional information indicates that contamination on or from the site poses a threat, or for a lack of compliance with a CO or closure requirement. Compliance with the maintenance plan is considered when evaluating the reopening criteria.

SUBMITTALS AND CONTACT INFORMATION

Site, case-related information and DNR contacts can be found online in the Bureau for Remediation and Redevelopment Tracking System (BRRTS) on the Web (BOTW); go to dnr.wi.gov and search "BOTW." Use the BRRTS ID # found at the top of this letter. The site can also be found on the map view, Remediation and Redevelopment Sites Map (RRSM) by searching "RRSM."

Send written notifications and inspection logs to the DNR using the RR Program Submittal Portal at dnr.wi.gov, search "RR submittal portal" (https://dnr.wi.gov/topic/Brownfields/Submittal.html). Questions on using this portal can be directed to the DNR project manager, Sarah Krueger, below or to the environmental program associate (EPA) for the regional DNR office. Visit dnr.wi.gov, search "RR contacts" and select the EPA tab (https://dnr.wi.gov/topic/Brownfields/Contact.html).

CLOSING

The DNR appreciates your efforts to restore the environment at this site. If you have any questions regarding this this letter, please contact DNR project manager, Sarah Krueger at (920) 510-8277 or sarah.krueger@wisconsin.gov.

Sincerely,

Roxanne N. Chronert
Team Supervisor, Northeast Region

COVER MAINTENANCE PLAN

January 24, 2022

Property Located at:

380/400 Bicentennial Court; 400/410 Fox Shores Drive; Lot 2 CSM 6200

DNR BRRTS # 02-45-582746

Parcel Identification Numbers #323040800, #323040801, #323040802, #323040804

Introduction

This document is the Maintenance Plan for building structures, asphalt, concrete, gravel, and soil cover at the above-referenced property in accordance with the requirements of s. NR 724.13 (2), Wis. Adm. Code. The maintenance activities relate to the existing pavement, structural, or soil covers which addresses or occupies the area over the contaminated soil and groundwater plume.

More site-specific information about this property/site may be found in:

- The case file in the DNR Northeast Regional office
- At http://dnr.wi.gov/topic/Brownfields/wrrd.html, which includes:
  - BRRTS on the Web (DNR's internet-based data base of contaminated sites) for the link to a PDF for site-specific information at the time of closure and on continuing obligations;
  - RR Sites Map for a map view of the site, and
- The DNR project manager for Outagamie County.

D.1. Descriptions:

Description of Contamination

Soil contaminated by polycyclic aromatic hydrocarbons (PAHs), resource conservation and recovery act (RCRA) metals, and/or volatile organic compounds (VOCs) has been identified at a depth of 0 to 4 feet across the property. Groundwater contaminated by arsenic and PAHs is located at a depth of 4 to 6 feet below ground surface. The extent of the soil and groundwater contamination is shown on the attached **Figure D.2**.

Description of the Cover to be Maintained

The cover consists of either building structures, 6-8 inches of gravel, impermeable surfaces such as concrete and asphalt, or a landscape cap made up of permeable filter fabric overlain with clean fill totaling 12 inches. The cap is located across the entire property as shown on the attached **Figure D.2**.

Cover Purpose

The buildings, gravel, paved surfaces, and landscaped soils in place cover the remaining contaminated soil and groundwater and serve as a barrier to prevent direct human contact with residual soil contamination that might otherwise pose a threat to human health. Based on the current use of the property as a residential apartment complex, the barrier should function as intended unless disturbed.

Annual Inspection

The cover overlying the contaminated soil and groundwater and as depicted in **Figure D.2.** will be inspected once a year, normally in the spring after all snow and ice is gone, for deterioration, cracks and other potential problems that can cause exposure to underlying soils. The inspections will be performed by the property owner or their designated representative. The inspections will be performed to evaluate damage due to settling, exposure to the weather, wear from traffic, increasing age and other factors. Any area where soils have become or are likely to become exposed will be documented.

A log of the inspections and any repairs will be maintained by the property owner and is included as D.4, Form 4400-305, Continuing Obligations Inspection and Maintenance Log. The log will include recommendations for necessary repair of any areas where underlying soils are exposed and where infiltration from the surface will not be effectively minimized. Once repairs are completed, they will be documented in the inspection log. A copy of the maintenance plan and inspection log will be kept at the site; or, if there is no acceptable place (for example, no building is present) to keep it at the site, at the address of the property owner and available for submittal or inspection by Wisconsin Department of Natural Resources (DNR) representatives upon their request.

Maintenance Activities

If problems are noted during the annual inspections or at any other time during the year, repairs will be scheduled as soon as practical. Repairs can include patching and filling or larger resurfacing or construction operations. In the event that necessary maintenance activities expose the underlying soil, the owner must inform maintenance workers of the direct contact exposure hazard and provide them with appropriate personal protection equipment (PPE). The owner must also sample any soil that is excavated from the site prior to disposal to ascertain if contamination remains. The soil must be treated, stored and disposed of by the owner in accordance with applicable local, state and federal law.

In the event the gravel, soil cover, and/or impervious surfaces overlying the contaminated soil and groundwater are removed or replaced, the replacement barrier must be equally impervious. Any replacement barrier will be subject to the same maintenance and inspection guidelines as outlined in this Maintenance Plan unless indicated otherwise by the DNR or its successor.

The property owner, in order to maintain the integrity of the gravel, soil cover, and impervious surfaces, will maintain a copy of this Maintenance Plan at the site; or, if there is no acceptable place to keep it at the site (for example, no building is present), at the address of the property owner and make it available to all interested parties (i.e. on-site employees, contractors, future property owners, etc.) for viewing.

Prohibition of Activities and Notification of DNR Prior to Actions Affecting a Cover

The following activities are prohibited on any portion of the property where [pavement, a building foundation, soil cover, engineered cap or other barrier] is required as shown on the attached map, unless prior written approval has been obtained from the Wisconsin Department of Natural Resources: 1) removal of the existing barrier; 2) replacement with another barrier; 3) excavating or grading of the land surface; 4) filling on capped or paved areas; 5) plowing for agricultural cultivation; 6) construction or placement of a building or other structure; 7) changing the use or occupancy of the property to single-family residential use.

If removal, replacement or other changes to a cover, or a building which is acting as a cover, are considered, the property owner will contact DNR at least 45 days before taking such an action, to determine whether further action may be necessary to protect human health, safety, or welfare or the environment, in accordance with s. NR 727.07, Wis. Adm. Code.

Amendment or Withdrawal of Maintenance Plan

This Maintenance Plan can be amended or withdrawn by the property owner and its successors with the written approval of DNR.

Continuing Obligations Inspection and Maintenance Log

Form 4400-305 (R 7/20)

Directions: In accordance with s. NR 727.05 (1) (b) 3., Wis. Adm. Code, use of this form for documenting the inspections and maintenance of certain continuing obligations is required. Personal information collected will be used for administrative purposes and may be provided to requesters to the extent required by Wisconsin's Public Records law [ss. 19.31-19.39, Wis. Stats.]. When using this form, identify the condition that is being inspected. See the closure approval letter for this site for requirements regarding the submittal of this form to the Department of Natural Resources. A copy of this inspection log is required to be maintained either on the property, or at a location specified in the closure approval letter. Do NOT delete previous inspection results. This form was developed to provide a continuous history of site inspection results. The Department of Natural Resources project manager is identified in the closure letter. The project manager may also be identified from the database, BRRTS on the Web, at http://dnr.wi.gov/botw/SetUpBasicSearchForm.do, by searching for the site using the BRRTS ID number, and then looking in the "Who" section.

Activity (Site) Name	BRRTS No.
Fox Shores Apartments	02-45-582746

Inspections are required to be conducted (see closure approval letter):

- (•) annually
- ( ) semi-annually
- ( ) other – specify _____

When submittal of this form is required, submit the form electronically to the DNR project manager. An electronic version of this filled out form, or a scanned version may be sent to the following email address (see closure approval letter):

Case Closure

SUBMIT AS UNBOUND PACKAGE IN THE ORDER SHOWN

Notice: Pursuant to ch. 292, Wis. Stats., and chs. NR 726 and 746, Wis. Adm. Code, this form is required to be completed for case closure requests. The closure of a case means that the Department of Natural Resources (DNR) has determined that no further response is required at that time based on the information that has been submitted to the DNR. All sections of this form must be completed unless otherwise directed by the Department. DNR will consider your request administratively complete when the form and all sections are completed, all attachments are included, and the applicable fees required under ch. NR 749, Wis. Adm. Code, are included, and sent to the proper destinations. Personal information collected will be used for administrative purposes and may be provided to requesters to the extent required by Wisconsin's Open Records Law (ss. 19.31 - 19.39, Wis. Stats.). Incomplete forms will be considered "administratively incomplete" and processing of the request will stop until required information is provided.

Fees and Mailing of Closure Request

1. **Send a copy of page one** of this form and the applicable ch. NR 749, Wis. Adm. Code, fee(s) to the DNR Regional EPA (Environmental Program Associate) at **http://dnr.wi.gov/topic/Brownfields/Contact.html#tabx3**. Check all fees that apply:

   ☒ $1,050 Closure Fee

   ☒ $350 Database Fee for Groundwater or Monitoring Wells (Not Abandoned)

   ☒ $300 Database Fee for Soil

   Total Amount of Payment $ $1,700.00

   ☐ Resubmittal, Fees Previously Paid

2. **Send one paper copy and one e-copy on compact disk of the entire closure package** to the Regional Project Manager assigned to your site. Submit as *unbound, separate documents* in the order and with the titles prescribed by this form. For electronic document submittal requirements, see **http://dnr.wi.gov/files/PDF/pubs/rr/RR690.pdf**.

Site Summary

If any portion of the Site Summary Section is not relevant to the case closure request, you must fully explain the reasons why in the relevant section of the form. All information submitted shall be legible. Providing illegible information will result in a submittal being considered incomplete until corrected.

1. General Site Information and Site History

A. Site Location: Describe the physical location of the site, both generally and specific to its immediate surroundings.
The Property consists of four parcels comprising approximately 3.86 acres to the north and west of Fox Shores Drive within the City of Kaukauna, Outagamie County, Wisconsin (SE 1/4 of the NE 1/4 of Section 23, T21N, R18E). Surrounding land uses consist of a mix of commercial and residential properties. The Property is currently occupied by River Ridge Apartments (formerly Fox Shores Apartments) for residential use. Current Property addresses consists of 400/410 Fox Shores Drive and 380/400 Bicentennial Court.

B. Prior and current site usage: Specifically describe the current and historic occupancy and types of use.
According to historical sources, the Property was developed as early as the 1890s. The Property and vicinity were developed as part of the Chicago and Northwest Railroad Shops. Areas of the Site were formerly utilized as a carpentry shop, machine shop, repair shop, engine room, coal room, blacksmith shop, supply warehouses, tin shop, and pipe shed. In 1983 the Property was redeveloped into multi-family residential apartments along Bicentennial Court. Additional apartments were later developed along Fox Shores Drive in 1992. The Property is currently occupied by River Ridge Apartments (formerly Fox Shores Apartments) and used for residential purposes.

C. Current zoning (e.g., industrial, commercial, residential) for the site and for neighboring properties, and how verified (Provide documentation in Attachment G).
Current zoning for the for the Site is Commercial Core (CCD) per October 1985 City of Kaukauna Zoning Map. Neighboring properties are denoted as Residential Multi-Family to the west, and Institutional to the south and east.

D. Describe how and when site contamination was discovered.
Partner Engineering and Science, Inc. (Partner) completed a Phase I Environmental Site Assessment (ESA) at the Property during July 2018. Several recognized environmental conditions (RECs) were identified during the Phase I ESA. To evaluate the RECs, a Phase II ESA was performed by Partner at the Property in November of 2018. As part of the Phase II ESA, five soil borings were completed for the collection of representative soil and groundwater samples along with the installation of three temporary sub-slab vapor sampling points. The Phase II ESA identified Resource Conservation and Recovery Act (RCRA) metals in soil at concentrations in excess of Wisconsin Administrative Code (Wis. Adm. Code) ch. NR720 residual contaminant levels (RCLs). Polynuclear aromatic hydrocarbons (PAHs) were also detected in the groundwater in excess of the Wis. Adm. Code ch. NR140 preventive action limit (PAL) and/or enforcement standards (ES) at the Site. Finally, dichlorodifluoromethane was detected above Wisconsin Department of Natural Resources (WDNR) residential sub-slab vapor risk screening levels.

E. Describe the type(s) and source(s) or suspected source(s) of contamination.
Laboratory analysis of soil samples collected from the Site reported RCRA metals, PAHs, and select volatile organic compounds (VOCs) exceeding Wis. Adm. Code ch. NR 720 RCLs for protection of groundwater. Various RCRA metals and PAHs were also detected in some samples above their respective industrial and non-industrial direct contact RCLs. Contaminants are believed to be the result of historical fill deposited across the site and the historic use of the site as a rail yard.

F. Other relevant site description information (or enter Not Applicable).
Not Applicable.

G. List BRRTS activity/site name and number for BRRTS activities at this source property, including closed cases.
02-45-582746 Fox Shores Apartments

H. List BRRTS activity/site name(s) and number(s) for all properties immediately adjacent to (abutting) this source property.
02-45-547911 Ghost Town Fitness Center; 02-45-589028 Chicago & Northwestern Railyard (Former); 02-45-548419 USACE - Parcel J (Kaukauna Power Canal)

2. General Site Conditions

A. Soil/Geology

i. Describe soil type(s) and relevant physical properties, thickness of soil column across the site, vertical and lateral variations in soil types.

Subsurface strata encountered in borings generally consisted of approximately three inches of asphalt or 1.5 to 2 feet of topsoil underlain by 0.5 to 2 feet of fine black sand and gravel underlain by 5 to 6 feet of silty clay.

ii. Describe the composition, location and lateral extent, and depth of fill or waste deposits on the site.

The results of the Phase II ESA and Site Investigation activities indicate that widespread historic fill consisting of sand and gravel is present across the entire Property at depths of up to 4 feet below ground surface (bgs). Laboratory analysis of soil samples collected from the Site reported RCRA metals, PAHs, and select VOCs exceeding Wis. Adm. Code ch. NR 720 RCLs for protection of groundwater. Various RCRA metals and PAHs were also detected in some samples above their respective industrial and non-industrial direct contact RCLs.

iii. Describe the depth to bedrock, bedrock type, competency and whether or not it was encountered during the investigation.

The bedrock in Outagamie County typically consists of dolomite, limestone, and shale of the Galena Formation of the Sinnipee Group (Luczaj, 2011). Depth to bedrock is estimated to exist between 5 and 50 feet bgs. Bedrock was not believed to be encountered during this investigation of the Property. Geoprobe drilling hit refusals at depths of 10 feet below grade. However, refusal was assumed to be within fractured bedrock or just above it as more competent bedrock is known to be present at depths of 13 to 18 feet below grade according to WDNR well construction records for wells constructed southeast of the Site.

iv. Describe the nature and locations of current surface cover(s) across the site (e.g., natural vegetation, landscaped areas, gravel, hard surfaces, and buildings).

Environmental actions associated with the presence of impacted soil/fill material at the Site are considered complete and are consistent with the 2021 Remedial Action Plan (RAP) and Material Management Plan (MMP). Select landscape areas across the Site were excavated to a maximum depth of one foot bgs. These areas were subsequently capped with an engineered geotextile fabric followed by 12 inches of clean soil and re-vegetated. Excavated impacted soils were redeposited back on-site as landscaped berms.

The berms were capped with engineered geotextile fabric followed by 12 inches of clean soil and re-vegetated. Remaining impacted soil areas are capped with gravel, or an impermeable surface such as building, sidewalk, or asphalt parking lot.

B. Groundwater

i. Discuss depth to groundwater and piezometric elevations. Describe and explain depth variations, including high and low water table elevation and whether free product affects measurement of water table elevation. Describe the stratigraphic unit(s) where water table was found or which were measured for piezometric levels.

The depth to groundwater was observed in temporary monitoring wells located on-site from approximately 3.5 to 6 feet bgs. No free product was detected in any of the temporary monitoring wells.

ii. Discuss groundwater flow direction(s), shallow and deep. Describe and explain flow variations, including fracture flow if present.

Regional shallow groundwater was determined to flow southeast along the Fox River, however, Site groundwater flow was found to follow a more southerly flow.

iii. Discuss groundwater flow characteristics: hydraulic conductivity, flow rate and permeability, or state why this information was not obtained.

While not calculated for the Site, hydraulic conductivity is considered to be low due to the silty clay substrate encountered during the Site Investigation.

iv. Identify and describe locations/distance of potable and/or municipal wells within 1200 feet of the site. Include general summary of well construction (geology, depth of casing, depth of screened or open interval).

Potable water at the Site is obtained from the City of Kaukauna municipal water system which is supplied by five groundwater wells located throughout the city. Depths of the wells range from 500 to 850 feet deep. None of the municipal wells are located within 1,200 feet of the Site.

3. Site Investigation Summary

A. General

i. Provide a brief summary of the site investigation history. Reference previous submittals by name and date. Describe site investigation activities undertaken since the last submittal for this project and attach the appropriate documentation in Attachment C, if not previously provided.

Partner completed a Phase I ESA at the Property during July 2018. Several RECs were identified during the Phase I ESA. To evaluate the RECs, a Phase II ESA was performed by Partner at the Property in November of 2018. As part of the Phase II ESA, five soil borings were completed for the collection of representative soil and groundwater samples along with the installation of three temporary sub-slab vapor sampling points. The Phase II ESA identified RCRA metals in soil at concentrations in excess of Wis. Adm. Code ch. NR720 RCLs. PAHs were also detected in the groundwater in excess of the Wis. Adm. Code ch. NR140 PAL and/or ES at the Site. Finally, dichlorodifluoromethane was detected above WDNR residential sub-slab vapor risk screening levels.

On December 3, 2018 Stantec was hired by Fox Investments, LLC to notify the WDNR of soil and groundwater contamination at the Site and possible vapor intrusion of dichlorodifluoromethane into Site buildings. On January 7, 2019, the WDNR opened BRRTS case #02-45-582746 for the Site and requested additional investigation to further characterize and define the extent of contamination at the Site and complete remedial actions needed for Site closure.

On February 25, 2019 Stantec conducted ambient air sampling within three apartment units. On February 26, 2019, Stantec personnel installed three sub-slab vapor points (VP-4, VP-5, and VP-6) within the same three apartment units where the ambient air samples were collected. An additional vapor point was also installed immediately adjacent to original vapor point (VP-2) from the November 2018 Phase II ESA completed by Partner.

On August 13, 2019, Stantec conducted additional sub-slab vapor sampling at vapor points VP-4, VP-5, and VP-6 within three apartment units at the Site. Samples were collected within the cooling months of summer to contrast earlier samples collected during the heating months of winter. Vapor samples were again sampled for dichlorodifluoromethane using EPA method TO-15.

With elevated dichlorodifluoromethane sub-slab concentrations at the Site, a source for the contamination was investigated. In order to determine a source for the sub-slab vapor issues at the Site, soil and groundwater investigation activities were conducted across the Site from May 2019 to April 2020. The results of these activities indicated the presence of widespread historic urban fill consisting of clay and sand/gravel across the Property at depths of up to three feet below ground surface. The sand and gravel fill were underlain by native silty clays. Laboratory analysis of soil samples collected from the Site reported RCRA metals, PAHs, and select VOCs exceeding Wis. Adm. Code ch. NR 720 RCLs for protection of groundwater. Various RCRA metals and PAHs were also detected in some samples above their respective industrial and non-industrial direct contact RCLs.

Due to the lack of dichlorodifluoromethane in soil samples collected at the Site, Stantec and the property owner continued to search for potential sources for the vapor intrusion issues. Upon further investigation, it was discovered that extruded polystyrene foam board was used as insulation on the interior foundation walls of the apartment buildings. It was further determined that dichlorodifluoromethane was a component that made up the extruded polystyrene foam insulation.

After determining that the extruded polystyrene foam board used on the apartment building's foundation walls could potentially be the source of the vapor intrusion issues at the Site, discussions were conducted with the WDNR. During those discussions, it was determined that construction/building materials are unregulated and that a subsequent release from these materials would not warrant further vapor assessment or require remedial action to be conducted.

During investigative activities, three rounds of groundwater sampling were completed. Groundwater analysis of water samples collected at the Property detected arsenic in three of the five temporary monitoring wells exceeding their respective Wis. Adm. Code ch. NR 140 PALs. Benzo(a)pyrene, benzo(b)fluoranthene, and/or chrysene were also identified within three temporary monitoring wells above the PAL with benzo(a)pyrene and benzo(b)fluoranthene above the ES during the most recent round of sampling at TW17. However, these were likely the result of colloidal material present in the sample from fine grained sediments surrounding the temporary well screen. No VOCs were detected in groundwater samples collected exceeding either the PAL or ES. Based on sampling results, it did not appear that contaminants in soil were significantly affecting groundwater quality at the Property. The results of the site investigation activities were submitted to the WDNR during June 2020. Based on the investigation activities completed to date, the WDNR indicated that the entire Property was impacted to some degree and required that contaminant concentrations in soil that exceed respective groundwater protection and/or direct contact RCLs be addressed.

On September 18, 2020, Stantec submitted a RAP to the WDNR proposing the excavation and capping of contaminated soil on the Site. Excavated soils unable to be reused on-site were proposed to be placed on the Adjacent Parcel under a low hazard exemption request. The low hazard exemption request was subsequently denied. As an alternative, the WDNR requested that soil investigation activities be completed on the Adjacent Parcel to determine if similar contaminants exist to those present on the Site. Laboratory analysis of shallow soil samples (0-4 feet bgs) collected from the Adjacent Parcel detected multiple RCRA metals, PAHs, and naphthalene exceeding the Wis. Adm. Code ch. NR720 RCLs for groundwater protection and/or non-industrial direct contact. Benzo(a)pyrene and arsenic were also detected in soil above the industrial direct contact RCL. Based on the sampling results, contaminants at the Adjacent Parcel were consistent with those generally observed in shallow soil at the Site. The Adjacent Parcel was subsequently added to the open BRRTS case for Fox Shores Apartments.

ii. Identify whether contamination extends beyond the source property boundary, and if so describe the media affected (e.g., soil, groundwater, vapors and/or sediment, etc.), and the vertical and horizontal extent of impacts.

Further investigation beyond the property lines was not warranted since contamination is likely related to the presence of historic fill which is widespread in this portion of the City and widespread throughout the area.

iii. Identify any structural impediments to the completion of site investigation and/or remediation and whether these impediments are on the source property or off the source property. Identify the type and location of any structural impediment (e.g., structure) that also serves as the performance standard barrier for protection of the direct contact or the groundwater pathway.

No structural impediments hindered investigation or remediation of the Site.

B. Soil

i. Describe degree and extent of soil contamination. Relate this to known or suspected sources and known or potential receptors/migration pathways.

Widespread historic urban fill consisting of clay and sand/gravel is present across the Property at depths of up to 3 feet bgs. The fill is underlain by native silty clay. Laboratory analysis of soil samples collected from the Site reported RCRA metals, PAHs, and select VOCs exceeding Wis. Adm. Code ch. NR 720 RCLs for protection of groundwater. Likewise, various RCRA metals and PAHs also were detected in samples above their respective industrial and non-industrial direct contact RCLs. Soil contamination is assumed to extend site-wide. Contaminants are believed to be the result of historical fill deposited across the site and the historic use of the site as a rail yard.

ii. Describe the concentration(s) and types of soil contaminants found in the upper four feet of the soil column.

Laboratory analysis of soil samples collected from the Site reported RCRA metals, PAHs, and select VOCs exceeding Wis. Adm. Code ch. NR 720 RCLs for protection of groundwater. Likewise, various RCRA metals and PAHs also were detected in samples above their respective industrial and non-industrial direct contact RCLs.

iii. Identify the ch. NR 720, Wis. Adm. Code, method used to establish the soil cleanup standards for this site. This includes a soil performance standard established in accordance with s. NR 720.08, a Residual Contaminant Level (RCL) established in accordance with s. NR 720.10 that is protective of groundwater quality, or an RCL established in accordance with s. NR 720.12 that is protective of human health from direct contact with contaminated soil. Identify the land use classification that was used to establish cleanup standards. Provide a copy of the supporting calculations/ information in Attachment C.

Stantec utilized the standard ch. NR 720, Wis. Adm. Code RCLs provided by the WDNR in spreadsheet form. The Wis. Adm. Code ch. NR 720, RCLs were most recently updated by the WDNR during December 2018.

C. Groundwater

i. Describe degree and extent of groundwater contamination. Relate this to known or suspected sources and known or potential receptors/migration pathways. Specifically address any potential or existing impacts to water supply wells or interception with building foundation drain systems.

Groundwater analysis of water samples collected at the Property detected arsenic in four of the five temporary monitoring wells (TW11, TW15, TW17) exceeding the respective Wis. Adm. Code ch. NR 140 PAL.

Groundwater sampling results also detected benzo(a)pyrene and benzo(b)fluoranthene exceeding their respective Wis. Adm. Code ch. NR 140 ES and chrysene above the respective Wis. Adm. Code ch. NR 140, PAL in temporary monitoring well TW17. No VOCs were detected exceeding either the PAL or ES. Based on sampling results, it does not appear that identified soil contamination is significantly affecting groundwater quality at the Property.

ii. Describe the presence of free product at the site, including the thickness, depth, and locations. Identify the depth and location of the smear zone.

No free product was observed during groundwater sampling.

D. Vapor

i. Describe how the vapor migration pathway was assessed, including locations where vapor, soil gas, or indoor air samples were collected. If the vapor pathway was not assessed, explain reasons why.

A Phase II ESA was performed by Partner at the Property in November of 2018. As part of the Phase II ESA, five soil borings were completed for the collection of representative soil and groundwater samples along with the installation of three temporary sub-slab vapor sampling points. Dichlorodifluoromethane was detected above WDNR residential sub-slab vapor risk screening levels.

On December 3, 2018 Stantec was hired by Fox Investments, LLC to notify the WDNR of soil and groundwater contamination at the Site and possible vapor intrusion of dichlorodifluoromethane into Site buildings. On January 7, 2019, the WDNR opened BRRTS case #02-45-582746 for the Site and requested additional investigation to further characterize and define the extent of contamination at the Site and complete remedial actions needed for Site closure. Due to the potential health threat of vapor intrusion, the WDNR requested that immediate actions be taken to investigate potential vapor intrusion impacts within the apartments at the Site.

On February 25, 2019 Stantec conducted ambient air sampling within three apartment units. On February 26, 2019, Stantec personnel installed three sub-slab vapor points (VP-4, VP-5, and VP-6) within the same three apartment units where the ambient air samples were collected. An additional vapor point was also installed immediately adjacent to original vapor point (VP-2) from the November 2018 Phase II ESA completed by Partner.

On August 13, 2019 Stantec conducted additional sub-slab vapor sampling at vapor points VP-4, VP-5, and VP-6 within three apartment units at the Site. Samples were collected within the cooling months of summer to contrast earlier samples collected during the heating months of winter. Vapor samples were again sampled for dichlorodifluoromethane using EPA method TO-15.

With elevated dichlorodifluoromethane sub-slab concentrations at the Site, a source for the contamination was investigated. In order to determine a source for the sub-slab vapor issues at the Site, soil and groundwater investigation activities were conducted across the Site from May 2019 to April 2020.

Due to the lack of dichlorodifluoromethane in soil samples collected at the Site, Stantec and the property owner continued to search for potential sources for the vapor intrusion issues. Upon further investigation, it was discovered that extruded polystyrene foam board was used as insulation on the interior foundation walls of the apartment buildings. It was further determined that dichlorodifluoromethane was a component that made up the extruded polystyrene foam insulation.

After determining that the extruded polystyrene foam board used on the apartment building's foundation walls could potentially be the source of the vapor intrusion issues at the Site, discussions were conducted with the WDNR. During those discussions, it was determined that construction/building materials are unregulated and that a subsequent release from these materials would not warrant further vapor assessment or require remedial action to be conducted.

ii. Identify the applicable DNR action levels and the land use classification used to establish them. Describe where the DNR action levels were reached or exceeded (e.g., sub slab, indoor air or both).

Not applicable. It was discovered that extruded polystyrene foam board was used as insulation on the interior foundation walls of the apartment buildings. It was further determined that dichlorodifluoromethane was a component that made up the extruded polystyrene foam insulation. Following this discovery, discussions were conducted with the WDNR which led to the determination that construction/building materials are unregulated and that a subsequent release from these materials would not warrant further vapor assessment or require remedial action to be conducted.

E. Surface Water and Sediment

i. Identify whether surface water and/or sediment was assessed and describe the impacts found. If this pathway was not assessed, explain why.

No surface water or sediment was assessed. No surface water or sediments exist on the Property. Site is covered by buildings, asphalt, concrete, gravel, and established grassy landscaped areas. Even though the site is adjacent to the Fox River, impacted soils are not likely to have migrated off-site to the river with the existing covers in place. In addition, adjacent areas of the Fox River are fast moving with little to no sediment existing in which to adequately sample.

ii. Identify any surface water and/or sediment action levels used to assess the impacts for this pathway and how these were derived. Describe where the DNR action levels were reached or exceeded.

Not Applicable. No surface water or sediments exist on the Property.

4. Remedial Actions Implemented and Residual Levels at Closure

A. General: Provide a brief summary of the remedial action history. List previous remedial action report submittals by name and date. Identify remedial actions undertaken since the last submittal for this project and provide the appropriate documentation in Attachment C.

On February 24, 2021, Stantec submitted a revised RAP and MMP to the WDNR to manage, redeposit, and cap excavated soil at the Site. The RAP and MMP was approved by the WDNR on June 2, 2021. The MMP outlined a strategy where all landscape areas across the Site were considered impacted and would either be excavated to a depth of 1-foot bgs and capped or have excavated soils redeposited on existing landscape areas and capped. The soil cap would consist of engineered geotextile fabric underlying twelve inches of clean fill and/or topsoil in the landscaped areas. Areas with an engineered cap (i.e., building, asphalt, concrete) would not be modified.

Prior to the start of remedial activities, all temporary monitoring wells (TW10, TW11, TW13, TW15, TW17) were located and abandoned in accordance with Wis. Adm. Code ch. NR 141. On June 30, 2021, Bartel Excavating, LLC and Versatile Lawn and Landscaping Inc. mobilized to the Site to begin remedial excavation activities. Silt fence and/or silt socks were installed along the eastern property boundary as well as areas surrounding the designated soil fill locations on-Site. Select landscape areas across the Site were excavated to a maximum depth of 1-foot bgs. Excavated soils were placed in one of four designated fill locations to create landscape berms. Excavated soils were generally placed within the closest fill area to prevent tracking of contaminated soils across the Site.

As excavation activities proceeded, several minor adjustments were made to the MMP. Upon visual inspection of the terrace area west of Fox Shores Drive, it was decided that no excavated soil would be deposited within it. Due to the narrow width of the area, a berm would not have been aesthetically pleasing nor have been practical to maintain as proposed. Therefore, the area was redesignated as an excavation area with contaminated soils being redeposited within the soil fill area located on the northeast portion of the Site.

In addition, the gravel area located north of the Ghost Town Fitness Center parking lot was not excavated. This area is

comprised of 8-10 inches of compacted gravel and has been used in the past as overflow parking for the fitness center. Due to the location and general use of the area, the gravel was left in place to act as a barrier to potentially contaminated soils beneath.

Likewise, the Fox Shores Apartment complex maintains several established landscape areas with mature plantings consisting of shrubs, bushes, and/or perennials. These locations were generally located immediately adjacent to the apartment buildings as well as near the garage units for the Fox Shores Drive apartments located on the northern portion of the Site. Because of the small size, accessibility, and established plantings within these landscape areas, no soil was excavated. The landscape areas, however, are currently capped with a minimum of 6 inches of decorative landscape gravel between the plantings.

Remedial excavation and redepositing of contaminated soils in landscape berms was completed on September 9, 2021. Remedial excavation activities generated approximately 1,230 cubic yards of RCRA metal, PAH, and VOC impacted soil which was redeposited on-site as landscaped berms. The depth of placed fill material ranged from six inches between the Bicentennial Court apartment buildings to a maximum depth of 2.5 feet above existing ground surface on the eastern portion of the Site. The soil fill areas were later capped with an engineered geotextile fabric followed by 12 inches of clean soil and reseeded.

On November 19, 2021, Stantec submitted a Remedial Actions Report documenting contaminated soil excavation, redeposition, and Site capping completed as a part of remedial actions. Remedial actions were completed according to the WDNR approved MMP. Remedial actions included documenting the excavation and redeposition of contaminated materials and placement of a cap existing of an engineered geotextile fabric followed by 12 inches of clean soil clean soil. Remaining soil contamination capped under BRRTS case (#02-45-582746) for the Fox Shores Apartments Site is the subject of this closure request.

B. Describe any immediate or interim actions taken at the site under ch NR 708, Wis. Adm. Code.
Not Applicable - No immediate or interim actions taken at the Property.

C. Describe the *active* remedial actions taken at the source property, including: type of remedial system(s) used for each media affected; the size and location of any excavation or in-situ treatment; the effectiveness of the systems to address the contaminated media and substances; operational history of the systems; and summarize the performance of the active remedial actions. Provide any system performance documentation in Attachment A.7.
Not Applicable - No active remediation systems utilized for the Property.

D. Describe the alternatives considered during the Green and Sustainable Remediation evaluation in accordance with NR 722.09 and any practices implemented as a result of the evaluation.
The remedial actions including the management of impacted materials on-site and capping the material in place which is considered a Green and Sustainable Remediation practice.

E. Describe the nature, degree and extent of residual contamination that will remain at the source property or on other affected properties after case closure.
VOC, RCRA metal, and PAH impacted soils remain across the entire Property. All landscape areas were either excavated to a depth of 1-foot bgs and capped or have excavated soils redeposited on existing landscape areas and capped. The soil cap consists of engineered geotextile fabric underlying twelve inches of clean fill and/or topsoil in the landscaped areas. Remaining areas across the Site without the soil cap are capped with an engineered cap (i.e., gravel, building, asphalt, concrete).

F. Describe the residual soil contamination within four feet of ground surface (direct contact zone) that attains or exceeds RCLs established under s. NR 720.12, Wis. Adm. Code, for protection of human health from direct contact.
Various RCRA metals and PAHs were detected in samples above their respective industrial and non-industrial direct contact RCLs. Soil contamination is assumed to extend site-wide. All landscape areas were either excavated to a depth of 1-foot bgs and capped or have excavated soils redeposited on existing landscape areas and capped. The soil cap consists of engineered geotextile fabric underlying twelve inches of clean fill and/or topsoil in the landscaped areas. Remaining areas without the soil cap are capped with an engineered cap (i.e., gravel, building, asphalt, concrete).

G. Describe the residual soil contamination that is above the observed low water table that attains or exceeds the soil standard(s) for the groundwater pathway.
Laboratory analysis of soil samples collected from the Site reported RCRA metals, PAHs, and select VOCs exceeding Wis. Adm. Code ch. NR 720 RCLs for protection of groundwater. Various RCRA metals and PAHs were also detected in some samples above their respective industrial and non-industrial direct contact RCLs. Soil contamination is assumed to extend site-wide. All landscape areas across the Site were either excavated to a depth of 1-foot bgs and capped or have excavated soils redeposited on existing landscape areas and capped. The soil cap consists of engineered geotextile fabric underlying twelve inches of clean fill and/or topsoil in the landscaped areas. Remaining areas across the Site without the soil cap are capped with an engineered cap (i.e., gravel, building, asphalt, concrete).

H. Describe how the residual contamination will be addressed, including but not limited to details concerning: covers, engineering controls or other barrier features; use of natural attenuation of groundwater; and vapor mitigation systems or measures.

Natural attenuation will be used to address remaining groundwater contamination.

I. If using natural attenuation as a groundwater remedy, describe how the data collected supports the conclusion that natural attenuation is effective in reducing contaminant mass and concentration (e.g., stable or receding groundwater plume).

As of the most recent round of quarterly groundwater sampling, benzo(a)pyrene and benzo(b)fluoranthene concentrations remain above the ES and chrysene concentrations remain above the PAL in TW17. Arsenic concentrations remain above the PAL in TW11, TW15, and TW17. PAH contamination in groundwater likely appears to be a product of fine sediment resulting from silty clay and sandy soils found at the Site along with the limitations of temporary monitoring wells.

In addition, elevated PAH concentrations in soil do not appear to translate to elevated concentrations in groundwater. For example, benzo(a)pyrene concentrations in soil samples collected from borings SB11 and SB17 were found to be in excess of industrial direct contact RCLs. However, no PAHs were detected in water samples collected from temporary monitoring well TW11 and concentrations of PAHs in TW17 were found to be just above the ES. This was also the case for benzo(b) fluoranthene concentrations found above non-industrial direct contact concentrations in borings SB11 and SB17. Therefore, based on sampling results, it does not appear that contaminants in soil are significantly affecting groundwater quality at the Property. No further groundwater monitoring appears to be necessary.

J. Identify how all exposure pathways (soil, groundwater, vapor) were removed and/or adequately addressed by immediate, interim and/or remedial action(s).

Environmental actions associated with the presence of impacted soil/fill material at the Site are considered complete and are consistent with the 2021 RAP and MMP. Select landscape areas across the Site were excavated to a maximum depth of one foot bgs. These areas were subsequently capped with an engineered geotextile fabric followed by 12 inches of clean soil and re-vegetated. Excavated impacted soils were redeposited back on-site as landscaped berms. The berms were capped with engineered geotextile fabric followed by 12 inches of clean soil and re-vegetated. Remaining impacted soil areas are capped with 6-8" of gravel, or an impermeable surface such as building, sidewalk, or asphalt parking lot.

K. Identify any system hardware anticipated to be left in place after site closure, and explain the reasons why it will remain.

Not applicable. No remediation system built for the Site.

L. Identify the need for a ch. NR 140, Wis. Adm. Code, groundwater Preventive Action Limit (PAL) or Enforcement Standard (ES) exemption, and identify the affected monitoring points and applicable substances.

As of the most recent round of quarterly groundwater sampling, benzo(a)pyrene and benzo(b)fluoranthene concentrations remain above the ES and chrysene concentrations remain above the PAL in TW17. Arsenic concentrations remain above the PAL in TW11, TW15, and TW17.

M. If a DNR action level for vapor intrusion was exceeded (for indoor air, sub slab, or both) describe where it was exceeded and how the pathway was addressed.

Not applicable. It was discovered that extruded polystyrene foam board was used as insulation on the interior foundation walls of the apartment buildings. It was further determined that dichlorodifluoromethane was a component that made up the extruded polystyrene foam insulation. After determining that the extruded polystyrene foam board used on the apartment building's foundation walls could potentially be the source of the vapor intrusion issues at the Site, discussions were conducted with the WDNR. During those discussions, it was determined that construction/building materials are unregulated and that a subsequent release from these materials would not warrant further vapor assessment or require remedial action to be conducted.

N. Describe the surface water and/or sediment contaminant concentrations and areas after remediation. If a DNR action level was exceeded, describe where it was exceeded and how the pathway was addressed.

Not applicable. No surface water or sediment existing on-site.

5. Continuing Obligations: Includes all affected properties and rights-of-way (ROWs). In certain situations, maintenance plans are also required, and must be included in Attachment D.

Directions: For each of the 3 property types below, check all situations that apply to this closure request.

(NOTE: Monitoring wells to be transferred to another site are addressed in Attachment E.)

	This situation applies to the following property or Right of Way (ROW): Property Type:			Case Closure Situation - Continuing Obligation (database fees will apply, ii. - xiv.)	Maintenance Plan Required
	Source Property	Affected Property (Off-Source)	ROW		
i.	☐	☒	☒	None of the following situations apply to this case closure request.	NA
ii.	☒	☐	☐	Residual groundwater contamination exceeds ch. NR 140 ESs.	NA
iii.	☒	☐	☐	Residual soil contamination exceeds ch. NR 720 RCLs.	NA
iv.				Monitoring Wells Remain:	
	☐	☐	☐	• Not Abandoned (filled and sealed)	NA
	☐	☐	☐	• Continued Monitoring (requested or required)	Yes
v.	☒	☐	☐	Cover/Barrier/Engineered Cover or Control for (soil) direct contact pathways (includes vapor barriers)	Yes
vi.	☐	☐	☐	Cover/Barrier/Engineered Cover or Control for (soil) groundwater infiltration pathway	Yes
vii.	☐	☐	☐	Structural Impediment: impedes completion of investigation or remedial action (not as a performance standard cover)	NA
viii.	☐	☐	☐	Residual soil contamination meets NR 720 industrial soil RCLs, land use is classified as industrial	NA

6. Underground Storage Tanks

A. Were any tanks, piping or other associated tank system components removed as part of the investigation or remedial action? ○ Yes ◉ No

B. Do any upgraded tanks meeting the requirements of ch. ATCP 93, Wis. Adm. Code, exist on the property? ○ Yes ◉ No

C. If the answer to question 6.B. is yes, is the leak detection system currently being monitored? ○ Yes ○ No

General Instructions

All information shall be legible. Providing illegible information will result in a submittal being considered incomplete until corrected. For each attachment (A-G), provide a Table of Contents page, listing all 'applicable' and 'not applicable' items by Closure Form titles (e.g., A.1. Groundwater Analytical Table, A.2. Soil Analytical Results Table, etc.). If any item is 'not applicable' to the case closure request, you must fully explain the reasons why.

Data Tables (Attachment A)

Directions for Data Tables:

- Use **bold** and italics font for information of importance on tables and figures. Use **bold** font for ch. NR 140, Wis. Adm. Code ES attainments or exceedances, and *italicized font* for ch. NR 140, Wis. Adm. Code, PAL attainments or exceedances.
- Use **bold** font to identify individual ch. NR 720 Wis. Adm. Code RCL exceedances. Tables should also include the corresponding groundwater pathway and direct contact pathway RCLs for comparison purposes. Cumulative hazard index and cumulative cancer risk exceedances should also be tabulated and identified on Tables A.2 and A.3.
- Do not use shading or highlighting on the analytical tables.
- Include on Data Tables the level of detection for results which are below the detection level (i.e., do not just list as no detect (ND)).
- Include the units on data tables.
- Summaries of all data must include information collected by previous consultants.
- Do not submit lab data sheets unless these have not been submitted in a previous report. Tabulate all data required in s. NR 716.15 (3)(c), Wis. Adm. Code, in the format required in s. NR 716.15(4)(e), Wis. Adm. Code.
- Include in Attachment A all of the following tables, in the order prescribed below, with the specific Closure Form titles noted on the separate attachments (e.g., Title: A.1. Groundwater Analytical Table; A.2. Soil Analytical Results Table, etc.).
- For required documents, each table (e.g., A.1., A.2., etc.) should be a separate Portable Document Format (PDF).

A. Data Tables

A.1. **Groundwater Analytical Table(s):** Table(s) showing the analytical results and collection dates for all groundwater sampling points (e.g., monitoring wells, temporary wells, sumps, extraction wells, potable wells) for which samples have been collected.

A.2. **Soil Analytical Results Table(s):** Table(s) showing **all** soil analytical results and collection dates. Indicate if sample was collected above or below the observed low water table (unsaturated versus saturated).

A.3. **Residual Soil Contamination Table(s):** Table(s) showing the analytical results of only the residual soil contamination at the time of closure. This table shall be a subset of table A.2 and should include only the soil sample locations that exceed an RCL. Indicate if sample was collected above or below the observed low water table (unsaturated versus saturated). Table A.3 is optional only if a total of fewer than 15 soil samples have been collected at the site.

A.4. **Vapor Analytical Table(s)**: Table(s) showing type(s) of samples, sample collection methods, analytical method, sample results, date of sample collection, time period for sample collection, method and results of leak detection, and date, method and results of communication testing.

A.5. **Other Media of Concern (e.g., sediment or surface water)**: Table(s) showing type(s) of sample, sample collection method, analytical method, sample results, date of sample collection, and time period for sample collection.

A.6. **Water Level Elevations:** Table(s) showing all water level elevation measurements and dates from all monitoring wells. If present, free product should be noted on the table.

A.7. **Other:** This attachment should include: 1) any available tabulated natural attenuation data; 2) data tables pertaining to engineered remedial systems that document operational history, demonstrate system performance and effectiveness, and display emissions data; and (3) any other data tables relevant to case closure not otherwise noted above. If this section is not applicable, please explain the reasons why.

Maps, Figures and Photos (Attachment B)

Directions for Maps, Figures and Photos:

- Provide on paper no larger than 11 x 17 inches, unless otherwise directed by the Department. Maps and figures may be submitted in a larger electronic size than 11 x 17 inches, in a PDF readable by the Adobe Acrobat Reader. However, those larger-size documents must be legible when printed.
- Prepare visual aids, including maps, plans, drawings, fence diagrams, tables and photographs according to the applicable portions of ss. NR 716.15(4), 726.09(2) and 726.11(3), (5) and (6), Wis. Adm. Code.
- Include all sample locations.
- Contour lines should be clearly labeled and defined.
- Include in Attachment B all of the following maps and figures, in the order prescribed below, with the specific Closure Form titles noted on the separate attachments (e.g., Title: B.1. Location Map; B.2. Detailed Site Map, etc).
- For the electronic copies that are required, each map (e.g., B.1.a., B.2.a, etc.,) should be a separate PDF.
- Maps, figures and photos should be dated to reflect the most recent revision.

B.1. Location Maps

B.1.a. **Location Map:** A map outlining all properties within the contaminated site boundaries on a United States Geological Survey (U.S.G.S.) topographic map or plat map in sufficient detail to permit easy location of all affected and/or adjacent parcels. If groundwater standards are exceeded, include the location of all potable wells, including municipal wells, within 1200 feet of the area of contamination.

B.1.b. **Detailed Site Map:** A map that shows all relevant features (buildings, roads, current ground surface cover, individual property boundaries for all affected properties, contaminant sources, utility lines, monitoring wells and potable wells) within the contaminated area. This map is to show the location of all contaminated public streets, and highway and railroad rights-of-way in relation to the source property and in relation to the boundaries of groundwater contamination attaining or exceeding a ch. NR 140 ES, and/or in relation to the boundaries of soil contamination attaining or exceeding a RCL. Provide parcel identification numbers for all affected properties.

B.1.c. **RR Sites Map:** From RR Sites Map (http://dnrmaps.wi.gov/sl/?Viewer=RR Sites) attach a map depicting the source property, and all open and closed BRRTS sites within a half-mile radius or less of the property.

B.2. Soil Figures

B.2.a. **Soil Contamination:** Figure(s) showing the location of **all** identified unsaturated soil contamination. Use a single contour to show the horizontal extent of each area of contiguous soil contamination that exceeds a soil to groundwater pathway RCL as determined under ch. NR 720.Wis. Adm. Code. A separate contour line should be used to indicate the horizontal extent of each area of contiguous soil contamination that exceeds a direct contact RCL exceedances (0-4 foot depth).

B.2.b. **Residual Soil Contamination:** Figure(s) showing only the locations of soil samples where unsaturated soil contamination remains at the time of closure (locations represented in Table A.3). Use a single contour to show the horizontal extent of each area of contiguous soil contamination that exceeds a soil to groundwater pathway RCL as determined under ch. NR 720 Wis. Adm. Code. A separate contour line should be used to indicate the horizontal extent of each area of contiguous soil contamination that exceeds a direct contact RCL exceedence (0-4 foot depth).

B.3. Groundwater Figures

B.3.a. **Geologic Cross-Section Figure(s):** One or more cross-section diagrams showing soil types and correlations across the site, water table and piezometric elevations, and locations and elevations of geologic rock units, if encountered. Display on one or more figures all of the following:

- Source location(s) and vertical extent of residual soil contamination exceeding an RCL. Distinguish between direct contact and the groundwater pathway RCLs.
- Source location(s) and lateral and vertical extent if groundwater contamination exceeds ch. NR 140 ES.
- Surface features, including buildings and basements, and show surface elevation changes.
- Any areas of active remediation within the cross section path, such as excavations or treatment zones.
- Include a map displaying the cross-section location(s), if they are not displayed on the Detailed Site Map (Map B.1.b.)

B.3.b. **Groundwater Isoconcentration:** Figure(s) showing the horizontal extent of the post-remedial groundwater contamination exceeding a ch. NR 140, Wis. Adm. Code, PAL and/or an ES. Indicate the date and direction of groundwater flow based on the most recent sampling data.

B.3.c. **Groundwater Flow Direction:** Figure(s) representing groundwater movement at the site. If the flow direction varies by more than 20° over the history of the site, submit two groundwater flow maps showing the maximum variation in flow direction.

B.3.d. **Monitoring Wells:** Figure(s) showing all monitoring wells, with well identification number. Clearly designate any wells that: (1) are proposed to be abandoned; (2) cannot be located; (3) are being transferred; (4) will be retained for further sampling, or (5) have been abandoned.

B.4. Vapor Maps and Other Media

B.4.a. **Vapor Intrusion Map:** Map(s) showing all locations and results for samples taken to investigate the vapor intrusion pathway in relation to residual soil and groundwater contamination, including sub-slab, indoor air, soil vapor, soil gas, ambient air, and communication testing. Show locations and footprints of affected structures and utility corridors, and/or where residual contamination poses a future risk of vapor intrusion.

B.4.b. **Other media of concern (e.g., sediment or surface water):** Map(s) showing all sampling locations and results for other media investigation. Include the date of sample collection and identify where any standards are exceeded.

B.4.c. **Other:** Include any other relevant maps and figures not otherwise noted above. (This section may remain blank).

B.5. Structural Impediment Photos: One or more photographs documenting the structural impediment feature(s) which precluded a complete site investigation or remediation at the time of the closure request. The photographs should document the area that could not be investigated or remediated due to a structural impediment. The structural impediment should be indicated on Figures B.2.a and B.2.b.

Documentation of Remedial Action (Attachment C)

Directions for Documentation of Remedial Action:

- Include in Attachment C all of the following documentation, in the order prescribed below, with the specific Closure Form titles noted on the separate attachments (e.g., Title: C.1. Site Investigation Documentation; C.2. Investigative Waste, etc.).
- If the documentation requested below has already been submitted to the DNR, please note the title and date of the report for that particular document requested.

C.1. **Site investigation documentation,** that has not otherwise been submitted with the Site Investigation Report.

C.2. **Investigative waste** disposal documentation.

C.3. Provide a **description of the methodology** used along with all supporting documentation if the RCLs are different than those contained in the Department's RCL Spreadsheet available at: http://dnr.wi.gov/topic/Brownfields/Professionals.html.

C.4. **Construction documentation** or as-built report for any constructed remedial action or portion of, or interim action specified in s. NR 724.02(1), Wis. Adm. Code.

C.5. **Decommissioning of Remedial Systems.** Include plans to properly abandon any systems or equipment.

C.6. **Other**. Include any other relevant documentation not otherwise noted above (This section may remain blank).

Maintenance Plan(s) and Photographs (Attachment D)

Directions for Maintenance Plans and Photographs:

Attach a maintenance plan for each affected property (source property, each off-source affected property) with continuing obligations requiring future maintenance (e.g., direct contact, groundwater protection, vapor intrusion). See Site Summary section 5 for all affected property(s) requiring a maintenance plan. Maintenance plan guidance and/or templates for: 1) Cover/barrier systems; 2) Vapor intrusion; and 3) Monitoring wells, can be found at: http://dnr.wi.gov/topic/Brownfields/Professionals.html#tabx3

D.1. **Descriptions of maintenance action(s) required for maximizing effectiveness of the engineered control, vapor mitigation system, feature or other action for which maintenance is required:**

- Provide brief descriptions of the type, depth and location of residual contamination.

- Provide a description of the system/cover/barrier/monitoring well(s) to be maintained.
- Provide a description of the maintenance actions required for maximizing effectiveness of the engineered control, vapor mitigation system, feature or other action for which maintenance is required.
- Provide contact information, including the name, address and phone number of the individual or facility who will be conducting the maintenance.

D.2. **Location map(s) which show(s):** (1) the feature that requires maintenance; (2) the location of the feature(s) that require(s) maintenance - on and off the source property; (3) the extent of the structure or feature(s) to be maintained, in relation to other structures or features on the site; (4) the extent and type of residual contamination; and (5) all property boundaries.

D.3. **Photographs** for site or facilities with a cover or other performance standard, a structural impediment or a vapor mitigation system, include one or more photographs documenting the condition and extent of the feature at the time of the closure request. Pertinent features shall be visible and discernible. Photographs shall be submitted with a title related to the site name and location, and the date on which it was taken.

D.4. **Inspection log**, to be maintained on site, or at a location specified in the maintenance plan or approval letter. The inspection and maintenance log is found at: http://dnr.wi.gov/files/PDF/forms/4400/4400-305.pdf.

Monitoring Well Information (Attachment E)

Directions for Monitoring Well Information:
For all wells that will remain in use, be transferred to another party, or that could not be located; attach monitoring well construction and development forms (DNR Form 4400-113 A and B: http://dnr.wi.gov/topic/groundwater/documents/forms/4400_113_1_2.pdf)

Select One:

◯ No monitoring wells were installed as part of this response action.

◉ All monitoring wells have been located and will be properly abandoned upon the DNR granting conditional closure to the site

◯ ***Select One or More:***

☐ Not all monitoring wells can be located, despite good faith efforts. Attachment E must include a description of efforts made to locate the wells.

☐ One or more wells will remain in use at the site after this closure. Attachment E must include documentation as to the reason (s) the well(s) will remain in use. When one or more monitoring wells will remain in use this is considered a continuing obligation and a maintenance plan will be required and must be included in Attachment D.

☐ One or more monitoring wells will be transferred to another owner upon case closure being granted. Attachment E should include documentation identifying the name, address and email for the new owner(s). Provide documentation from the party accepting future responsibility for monitoring well(s).

Source Legal Documents (Attachment F)

Directions for Source Legal Documents:
Label documents with the specific closure form titles (e.g., F.1. Deed, F.2. Certified Survey Map, etc.). Include all of the following documents, in the order listed:

F.1. **Deed:** The most recent deed with legal description clearly listed.

Note: *If a property has been purchased with a land contract and the purchaser has not yet received a deed, a copy of the land contract which includes the legal description shall be submitted instead of the most recent deed. If the property has been inherited, written documentation of the property transfer should be submitted along with the most recent deed.*

F.2. **Certified Survey Map:** A copy of the certified survey map or the relevant section of the recorded plat map for those properties where the legal description in the most recent deed refers to a certified survey map or a recorded plat map. In cases where the certified survey map or recorded plat map are not legible or are unavailable, a copy of a parcel map from a county land information office may be substituted. A copy of a parcel map from a county land information office shall be legible, and the parcels identified in the legal description shall be clearly identified and labeled with the applicable parcel identification number.

F.3. **Verification of Zoning**: Documentation (e.g., official zoning map or letter from municipality) of the property's or properties' current zoning status.

F.4. **Signed Statement:** A statement signed by the Responsible Party (RP), which states that he or she believes that the attached legal description(s) accurately describe(s) the correct contaminated property or properties. This section applies to the source property only. Signed statements for Other Affected Properties should be included in Attachment G.

Notifications to Owners of Affected Properties (Attachment G)

Directions for Notifications to Owners of Affected Properties:

Complete the table on the following page for sites which require notification to owners of affected properties pursuant to ch. 292, Wis. Stats. and ch. NR 725 and 726, Wis. Adm. Code. Personal information collected will be used for administrative purposes and may be provided to requesters to the extent required by Wisconsin's Open Records law [ss. 19.31- 19.39,Wis. Stats.]. The DNR's "Guidance on Case Closure and the Requirements for Managing Continuing Obligations" (PUB-RR-606) lists specific notification requirements http://dnr.wi.gov/files/PDF/pubs/rr/RR606.pdf.

State law requires that the responsible party provide a 30-day, written advance notification to certain persons prior to applying for case closure. This requirement applies if: (1) the person conducting the response action does not own the source property; (2) the contamination has migrated onto another property; and/or (3) one or more monitoring wells will not be abandoned. Use form 4400-286, Notification of Continuing Obligations and Residual Contamination, at http://dnr.wi.gov/files/PDF/forms/4400/4400-286.pdf

Include a copy of each notification sent and accompanying proof of delivery, i.e., return receipt or signature confirmation.

Include the following documents for each property, keeping each property's documents grouped together and labeled with the letter G and the corresponding ID number from the table on the following page. (Source Property documents should only be included in Attachment F):

- **Deed:** The most recent deed with legal descriptions clearly listed for all affected properties.
  Note: If a property has been purchased with a land contract and the purchaser has not yet received a deed, a copy of the land contract which includes the legal description shall be submitted instead of the most recent deed. If the property has been inherited, written documentation of the property transfer should be submitted along with the most recent deed.
- **Certified Survey Map:** A copy of the certified survey map or the relevant section of the recorded plat map for those properties where the legal description in the most recent deed refers to a certified survey map or a recorded plat map. In cases where the certified survey map or recorded plat map are not legible or are unavailable, a copy of a parcel map from a county land information office may be substituted. A copy of a parcel map from a county land information office shall be legible, and the parcels identified in the legal description shall be clearly identified and labeled with the applicable parcel identification number.
- **Verification of Zoning:** Documentation (e.g., official zoning map or letter from municipality) of the property's or properties' current zoning status.
- **Signed Statement:** A statement signed by the Responsible Party (RP), which states that he or she believes the attached legal description(s) accurately describe(s) the correct contaminated property or properties.

Signatures and Findings for Closure Determination

This page has been updated as of February 2019 to comply with the requirements of Wis. Admin. Code ch. NR 712.

Check the correct box for this case closure request and complete the corresponding certification statement(s) listed below to demonstrate that the requirements of Wis. Admin. Code ch. NR 712 have been met. The responsibility for signing the certification may not be delegated per Wis. Admin. Code § NR 712.09 (1). Per Wis. Admin. Code § 712.05 (1), the work must be conducted or supervised by the person certifying.

- (●) The investigation and/or response action(s) for this site evaluated and/or addressed groundwater (including natural attenuation remedies). Both a professional engineer and a hydrogeologist must sign this document per Wis. Admin. Code ch. NR 712.
- ( ) The investigation and the response action(s) for this site did not evaluate or address groundwater. A professional engineer must sign this document per Wis. Admin. Code ch. NR 712.

Engineering Certification

I, Hiedi Waller, hereby certify that I am a registered professional engineer in the State of Wisconsin, registered in accordance with the requirements of ch. A-E 4, Wis. Adm. Code; that this document has been prepared in accordance with the Rules of Professional Conduct in ch. A-E 8, Wis. Adm. Code; and that, to the best of my knowledge, all information contained in this document is correct and the document was prepared in compliance with all applicable requirements in chs. NR 700 to 726, Wis. Adm. Code.

Signature Hiedi Ann Waller P. E. # E-33741

Title Senior Engineer P.E. Stamp

Hydrogeologist Certification

I, Stu Gross, hereby certify that I am a hydrogeologist as that term is defined in s. NR 712.03 (1), Wis. Adm. Code, am registered in accordance with the requirements of ch. GHSS 2, Wis. Adm. Code, or licensed in accordance with the requirements of ch. GHSS 3, Wis. Adm. Code, and that, to the best of my knowledge, all of the information contained in this document is correct and the document was prepared in compliance with all applicable requirements in chs. NR 700 to 726, Wis. Adm. Code.

Signature Stuart Gross

Key:

RCRA = Resource Conservation and Recovery Act
<x = compound not detected to a detection limit of x
XXX = exceeds WDNR Non-Industrial RCL for direct contact risk
XXX = exceeds WDNR Industrial RCL for direct contact risk
XXX = exceeds WDNR RCL for protection of groundwater
mg/kg = milligram per kilogram
NE = not established by WAC (Wis. Adm. Code) or WDNR Soil RCL Summary Table
"J" = analyte detected between the limit of detection and limit of quantification
RCL = residual contaminant level
fbg = feet below ground
= Boring completed and sample collected by Partner Engineering and Science, Inc.

Notes:
WDNR soil RCL Summary table (December 2018) used to establish RCLs for groundwater protection and direct contact.
For the purpose of this evaluation under ch. NR 700, background threshold values are being considered as representative of background conditions.
However, constituent concentrations less than background threshold values may represent a potential health risk if concentrations are greater than health-based standards.

Key:

<x = compound not detected to a detection limit of x
XXX = exceeds WDNR Non-Industrial RCL for direct contact risk
XXX = exceeds WDNR Industrial RCL for direct contact risk
XXX = exceeds WDNR RCL for protection of groundwater
µg/kg = milligram per kilogram
NE = not established by WAC (Wis. Adm. Code) or WDNR Soil RCL Summary Table
"J" = analyte detected between the limit of detection and limit of quantification
RCL = residual contaminant level
fbg = feet below ground
= Boring completed and sample collected by Partner Engineering and Science, Inc.

Notes: WDNR soil RCL Summary table (December 2018) used to establish RCLs for groundwater protection and direct contact.

Notes:

WDNR soil RCL Summary table (December 2018) used to establish RCLs for groundwater protection and direct contact.

For the purpose of this evaluation under ch. NR 700, background threshold values are being considered as representative of background conditions.

However, constituent concentrations less than background threshold values may represent a potential health risk if concentrations are greater than health-based standards.

COVER MAINTENANCE PLAN

January 24, 2022

Property Located at:

380/400 Bicentennial Court; 400/410 Fox Shores Drive; Lot 2 CSM 6200

DNR BRRTS # 02-45-582746

Parcel Identification Numbers #323040800, #323040801, #323040802, #323040804

Introduction

This document is the Maintenance Plan for building structures, asphalt, concrete, gravel, and soil cover at the above-referenced property in accordance with the requirements of s. NR 724.13 (2), Wis. Adm. Code. The maintenance activities relate to the existing pavement, structural, or soil covers which addresses or occupies the area over the contaminated soil and groundwater plume.

More site-specific information about this property/site may be found in:

- The case file in the DNR Northeast Regional office
- At http://dnr.wi.gov/topic/Brownfields/wrrd.html, which includes:
  - BRRTS on the Web (DNR's internet-based data base of contaminated sites) for the link to a PDF for site-specific information at the time of closure and on continuing obligations;
  - RR Sites Map for a map view of the site, and
- The DNR project manager for Outagamie County.

D.1. Descriptions:

Description of Contamination

Soil contaminated by polycyclic aromatic hydrocarbons (PAHs), resource conservation and recovery act (RCRA) metals, and/or volatile organic compounds (VOCs) has been identified at a depth of 0 to 4 feet across the property. Groundwater contaminated by arsenic and PAHs is located at a depth of 4 to 6 feet below ground surface. The extent of the soil and groundwater contamination is shown on the attached **Figure D.2**.

Description of the Cover to be Maintained

The cover consists of either building structures, 6-8 inches of gravel, impermeable surfaces such as concrete and asphalt, or a landscape cap made up of permeable filter fabric overlain with clean fill totaling 12 inches. The cap is located across the entire property as shown on the attached **Figure D.2**.

Cover Purpose

The buildings, gravel, paved surfaces, and landscaped soils in place cover the remaining contaminated soil and groundwater and serve as a barrier to prevent direct human contact with residual soil contamination that might otherwise pose a threat to human health. Based on the current use of the property as a residential apartment complex, the barrier should function as intended unless disturbed.

Annual Inspection

The cover overlying the contaminated soil and groundwater and as depicted in **Figure D.2.** will be inspected once a year, normally in the spring after all snow and ice is gone, for deterioration, cracks and other potential problems that can cause exposure to underlying soils. The inspections will be performed by the property owner or their designated representative. The inspections will be performed to evaluate damage due to settling, exposure to the weather, wear from traffic, increasing age and other factors. Any area where soils have become or are likely to become exposed will be documented.

A log of the inspections and any repairs will be maintained by the property owner and is included as D.4, Form 4400-305, Continuing Obligations Inspection and Maintenance Log. The log will include recommendations for necessary repair of any areas where underlying soils are exposed and where infiltration from the surface will not be effectively minimized. Once repairs are completed, they will be documented in the inspection log. A copy of the maintenance plan and inspection log will be kept at the site; or, if there is no acceptable place (for example, no building is present) to keep it at the site, at the address of the property owner and available for submittal or inspection by Wisconsin Department of Natural Resources (DNR) representatives upon their request.

Maintenance Activities

If problems are noted during the annual inspections or at any other time during the year, repairs will be scheduled as soon as practical. Repairs can include patching and filling or larger resurfacing or construction operations. In the event that necessary maintenance activities expose the underlying soil, the owner must inform maintenance workers of the direct contact exposure hazard and provide them with appropriate personal protection equipment (PPE). The owner must also sample any soil that is excavated from the site prior to disposal to ascertain if contamination remains. The soil must be treated, stored and disposed of by the owner in accordance with applicable local, state and federal law.

In the event the gravel, soil cover, and/or impervious surfaces overlying the contaminated soil and groundwater are removed or replaced, the replacement barrier must be equally impervious. Any replacement barrier will be subject to the same maintenance and inspection guidelines as outlined in this Maintenance Plan unless indicated otherwise by the DNR or its successor.

The property owner, in order to maintain the integrity of the gravel, soil cover, and impervious surfaces, will maintain a copy of this Maintenance Plan at the site; or, if there is no acceptable place to keep it at the site (for example, no building is present), at the address of the property owner and make it available to all interested parties (i.e. on-site employees, contractors, future property owners, etc.) for viewing.

Prohibition of Activities and Notification of DNR Prior to Actions Affecting a Cover

The following activities are prohibited on any portion of the property where [pavement, a building foundation, soil cover, engineered cap or other barrier] is required as shown on the attached map, unless prior written approval has been obtained from the Wisconsin Department of Natural Resources: 1) removal of the existing barrier; 2) replacement with another barrier; 3) excavating or grading of the land surface; 4) filling on capped or paved areas; 5) plowing for agricultural cultivation; 6) construction or placement of a building or other structure; 7) changing the use or occupancy of the property to single-family residential use.

If removal, replacement or other changes to a cover, or a building which is acting as a cover, are considered, the property owner will contact DNR at least 45 days before taking such an action, to determine whether further action may be necessary to protect human health, safety, or welfare or the environment, in accordance with s. NR 727.07, Wis. Adm. Code.

Amendment or Withdrawal of Maintenance Plan

This Maintenance Plan can be amended or withdrawn by the property owner and its successors with the written approval of DNR.

Continuing Obligations Inspection and Maintenance Log

Form 4400-305 (R 7/20)

Directions: In accordance with s. NR 727.05 (1) (b) 3., Wis. Adm. Code, use of this form for documenting the inspections and maintenance of certain continuing obligations is required. Personal information collected will be used for administrative purposes and may be provided to requesters to the extent required by Wisconsin's Public Records law [ss. 19.31-19.39, Wis. Stats.]. When using this form, identify the condition that is being inspected. See the closure approval letter for this site for requirements regarding the submittal of this form to the Department of Natural Resources. A copy of this inspection log is required to be maintained either on the property, or at a location specified in the closure approval letter. Do NOT delete previous inspection results. This form was developed to provide a continuous history of site inspection results. The Department of Natural Resources project manager is identified in the closure letter. The project manager may also be identified from the database, BRRTS on the Web, at http://dnr.wi.gov/botw/SetUpBasicSearchForm.do, by searching for the site using the BRRTS ID number, and then looking in the "Who" section.

Activity (Site) Name	BRRTS No.
Fox Shores Apartments	02-45-582746

Inspections are required to be conducted (see closure approval letter):

- (•) annually
- ( ) semi-annually
- ( ) other – specify _____

When submittal of this form is required, submit the form electronically to the DNR project manager. An electronic version of this filled out form, or a scanned version may be sent to the following email address (see closure approval letter):

TABLE OF CONTENTS

G.1. Notifications to Owners of Affected Properties…….....42 pages

Section A: Deeded Property Notification: Residual Contamination and/or Continuing Obligations

KEEP THIS DOCUMENT WITH YOUR PROPERTY RECORDS

518 Main Street #346
Wrightstown, WI, 54180

Dear Mr. Rankin:

I am providing this letter to inform you of the location and extent of contamination remaining on your property, and of certain long-term responsibilities (continuing obligations) for which you may become responsible.
I have investigated a release of:
polycyclic aromatic hydrocarbons (PAHs), resource conservation and recovery act (RCRA)
metals, and/or volatile organic compounds (VOCs)
on 400/410 Fox Shores Dr., 380/400 Bicentennial Ct., Par. #323040804, Kaukauna, WI, 54130 that has shown that contamination remains on this source property.
I have responded to the release and will be requesting that the Department of Natural Resources (DNR) grant case closure. Closure means that the DNR will not be requiring any further investigation or cleanup action to be taken. However, continuing obligations may be imposed as a condition of closure approval.

You have 30 days to comment on the attached legal description of your property and on the proposed closure request:

Please review the enclosed legal description of your property, and notify Jeffrey Brand at 1165 Scheuring Road, De Pere, WI, 54115 within the next 30 days if the legal description is incorrect.

The DNR will not review my closure request for at least 30 days after the date of receipt of this letter. As an affected property owner, you have a right to contact the DNR to provide any technical information that you may have that indicates that closure should not be granted for this site. If you would like to submit any information that is relevant to this closure request, or if you want to waive the 30 day comment period, you should mail that information to the DNR contact: 2984 Shawano Ave, Green Bay, WI, 54313, or at sarah.krueger@wisconsin.gov.

Your Long-Term Responsibilities as a Property Owner and Occupant:

The responses included
remedial excavation of soil and the placement of a site-wide cap.
The continuing obligations I am proposing that affect your property are listed below, under the heading **Continuing Obligations**. Under s. 292.12 (5), Wis. Stats., current and future owners and occupants of this property are responsible for complying with continuing obligations imposed as part of an approved closure.

The fact sheet "Continuing Obligations for Environmental Protection" (DNR publication RR 819) has been included with this letter, to help explain the responsibilities you may have for maintenance of a certain continuing obligation, the limits of any liability for investigation and cleanup of contamination, and how these differ. If the fact sheet is lost, you may obtain copies at http://dnr.wi.gov/files/PDF/pubs/rr/RR819.pdf.

Contract for responsibility for continuing obligation:

Before I request closure, I will need to inform the DNR as to whom will be responsible for the continuing obligation/s on your property.
Fox Shores LLC - Logan Rankin

Under s. 292.12, Wis. Stats., the responsibility for maintaining all necessary continuing obligations for your property will fall on you or any subsequent property owner, unless another person has a legally enforceable responsibility to comply with the requirements of the final closure letter. If you need more time to finalize an agreement on the responsibility for the continuing obligations on your Property, you may request additional time from the DNR contact identified in **Contact Information.**

(Note: Future property owners would need to negotiate a new agreement.)

Remaining Contamination:

Soil Contamination:

Soil contamination remains at :
400/410 Fox Shores Dr., 380/400 Bicentennial Ct., Par. #323040804

The remaining contaminants include:
PAHs, RCRA metals, VOCs

at levels which exceed the soil standards found in ch. NR 720, Wis. Adm. Code. The following steps have been taken to address any exposure to the remaining soil contamination.
Soil contamination has been capped with an engineered fabric followed by 12 inches of clean soil.

Groundwater Contamination:

Groundwater contamination originated at the property located at 400/410 Fox Shores Dr., 380/400 Bicentennial Ct., Par. #323040804, Kaukauna, WI, 54130. The levels of
PAH
contamination in the groundwater on your property are above the state groundwater enforcement standards found in ch. NR 140, Wis. Adm. Code.

However, the environmental consultants who have investigated this contamination have informed me that this groundwater contaminant plume is stable or receding and will naturally degrade over time. I believe that allowing natural attenuation, or the breakdown of contaminants in groundwater due to naturally occurring processes, to complete the cleanup at this site will meet the case closure requirements of ch. NR 726, Wis. Adm. Code. As part of my request for case closure, I am requesting that the DNR accept natural attenuation as the final remedy for this site.

The following DNR fact sheet (RR 671, "What Landowners Should Know: Information About Using Natural Attenuation to Clean Up Contaminated Groundwater") has been included with this notification, to help explain the use of natural attenuation as a remedy. If the fact sheet is lost, you may obtain a copy at http://dnr.wi.gov/files/PDF/pubs/rr/RR671.pdf.

Continuing Obligations on Your Property: As part of the cleanup, I am proposing that the following continuing obligations be used at your property, to address future exposure to residual contamination. If my closure request is approved, you will be responsible for the following continuing obligations.

To construct a new well or to reconstruct an existing well, the property owner at the time of construction or reconstruction will need to obtain prior approval from the DNR. See **Well Construction Requirements**. Typically, this results in casing off a portion of the aquifer during drilling, when needed, to protect the water supply.

Residual Soil Contamination:

If soil is excavated from the areas with residual contamination, the property owner at the time of excavation will be responsible for the following:

- determine if contamination is present
- determine whether the material would be considered solid or hazardous waste
- ensure that any storage, treatment or disposal is in compliance with applicable statutes and rules.

Contaminated soil may be managed in-place, in accordance with ch. NR 718, Wis. Adm. Code, with prior DNR approval. In addition, all current and future property owners and occupants of the property and right-of-way holders need to be aware that excavation of the contaminated soil may pose an inhalation or other direct contact hazard and as a result special precautions may need to be taken during excavation activities to prevent a health threat to humans.

Depending on site-specific conditions, construction over contaminated soils or groundwater may result in vapor migration of contaminants into enclosed structures or migration along underground utility lines. The potential for vapor inhalation and means of mitigation should be evaluated when planning any future redevelopment, and measures should be taken to ensure the continued protection of public health, safety, welfare and the environment at the site.

Maintenance of a Cover:

A soil cover/engineered cover/other has been placed over remaining contamination to limit contact with the soil,
and this cover will need to be maintained. Inspections will be required, and submittal of inspection reports may be required. Certain activities which would disturb the cover or barrier will be prohibited.
If the cover was intended for industrial or commercial use, notification of the DNR may be required before changing the land use to a residential type use, to determine if the cover will be protective for that use.
A maintenance plan is attached, which describes the maintenance activities likely to be required.
An updated maintenance plan will be provided at closure, if the requires changes to the maintenance plan.

A map, figure 3 , is attached, which shows the location of the extent of contamination and the extent of the cover.

Maintenance and Audits of Continuing Obligations:

If compliance with a maintenance plan is required as part of a continuing obligation, an inspection log will need to be filled out periodically, and kept available for inspection by the DNR. Submittal of the inspection log may also be required. You will also need to notify any future owners or occupants of this property of the need to maintain the continuing obligation and to document that maintenance in the inspection log. Periodic audits of these continuing obligations may be conducted by the DNR, to ensure that potential exposure to residual contamination is being addressed. The DNR provides notification before conducting site visits as part of the audit.

Well Construction Requirements:

If this site is closed, all properties within the site boundaries where contamination remains, or where a continuing obligation is applied, will be listed on the Bureau for Remediation and Redevelopment Tracking System (BRRTS) on the Web, at https://dnr.wi.gov/topic/Brownfields/WRRD.html. Inclusion on this database provides public notice of remaining contamination and of any continuing obligations. Documents can be viewed on this database, and include final closure letters, site maps and any applicable maintenance plans. The location of the site may also be viewed on the Remediation and Redevelopment Sites Map (RR Sites Map), at the same internet address listed above.

DNR approval prior to well construction or reconstruction is required in accordance with s. NR 812.09 (4) (w), Wis. Adm. Code. This requirement applies to private drinking water wells and high capacity wells. Special well construction standards may be necessary to protect the well from the remaining contamination. The property owner needs to first obtain approval from a regional water supply specialist in DNR's Drinking Water and Groundwater Program. A well driller can help complete this form. The well construction application, form 3300−254, is on the internet at https://dnr.wi.gov/files/PDF/forms/3300/3300-254.pdf.

Site Closure:

If the DNR grants closure, you will receive a letter which defines the specific continuing obligations on your property. The status of the site (open or closed) may also be checked by searching BRRTS on the Web. You may view or download a copy of the closure letter (sent to the responsible party) from BRRTS on the Web. You may also request a copy of the closure letter from the **responsible party** or by writing to the DNR contact, at Sarah Krueger, sarah.krueger@wisconsin.gov, (920) 510-8277 . The final closure letter will contain a description of the continuing obligation, any prohibitions on activities and will include any applicable maintenance plan.

If you have any questions regarding this notification, I can be reached at: (920) 883-8501 , Jeff.Brand@Stantec.com .

COVER MAINTENANCE PLAN

January 24, 2022

Property Located at:

380/400 Bicentennial Court; 400/410 Fox Shores Drive; Lot 2 CSM 6200

DNR BRRTS # 02-45-582746

Parcel Identification Numbers #323040800, #323040801, #323040802, #323040804

Introduction

This document is the Maintenance Plan for building structures, asphalt, concrete, gravel, and soil cover at the above-referenced property in accordance with the requirements of s. NR 724.13 (2), Wis. Adm. Code. The maintenance activities relate to the existing pavement, structural, or soil covers which addresses or occupies the area over the contaminated soil and groundwater plume.

More site-specific information about this property/site may be found in:

- The case file in the DNR Northeast Regional office
- At http://dnr.wi.gov/topic/Brownfields/wrrd.html, which includes:
  - BRRTS on the Web (DNR's internet-based data base of contaminated sites) for the link to a PDF for site-specific information at the time of closure and on continuing obligations;
  - RR Sites Map for a map view of the site, and
- The DNR project manager for Outagamie County.

D.1. Descriptions:

Description of Contamination

Soil contaminated by polycyclic aromatic hydrocarbons (PAHs), resource conservation and recovery act (RCRA) metals, and/or volatile organic compounds (VOCs) has been identified at a depth of 0 to 4 feet across the property. Groundwater contaminated by arsenic and PAHs is located at a depth of 4 to 6 feet below ground surface. The extent of the soil and groundwater contamination is shown on the attached **Figures 1 and 2**.

Description of the Cover to be Maintained

The cover consists of either building structures, gravel, impermeable surfaces such as concrete and asphalt, or a landscape cap made up of permeable filter fabric overlain with clean fill totaling 12 inches. The cap is located across the entire property as shown on the attached **Figure 3**.

Cover Purpose

The buildings, gravel, paved surfaces, and landscaped soils in place cover the remaining contaminated soil and groundwater and serve as a barrier to prevent direct human contact with residual soil contamination that might otherwise pose a threat to human health. Based on the current use of the property as a residential apartment complex, the barrier should function as intended unless disturbed.

SOURCE PROPERTY

Annual Inspection

The cover overlying the contaminated soil and groundwater and as depicted in **Figures 1 and 2** will be inspected once a year, normally in the spring after all snow and ice is gone, for deterioration, cracks and other potential problems that can cause exposure to underlying soils. The inspections will be performed by the property owner or their designated representative. The inspections will be performed to evaluate damage due to settling, exposure to the weather, wear from traffic, increasing age and other factors. Any area where soils have become or are likely to become exposed will be documented.

A log of the inspections and any repairs will be maintained by the property owner and is included as D.4, Form 4400-305, Continuing Obligations Inspection and Maintenance Log. The log will include recommendations for necessary repair of any areas where underlying soils are exposed and where infiltration from the surface will not be effectively minimized. Once repairs are completed, they will be documented in the inspection log. A copy of the maintenance plan and inspection log will be kept at the site; or, if there is no acceptable place (for example, no building is present) to keep it at the site, at the address of the property owner and available for submittal or inspection by Wisconsin Department of Natural Resources (DNR) representatives upon their request.

Maintenance Activities

If problems are noted during the annual inspections or at any other time during the year, repairs will be scheduled as soon as practical. Repairs can include patching and filling or larger resurfacing or construction operations. In the event that necessary maintenance activities expose the underlying soil, the owner must inform maintenance workers of the direct contact exposure hazard and provide them with appropriate personal protection equipment (PPE). The owner must also sample any soil that is excavated from the site prior to disposal to ascertain if contamination remains. The soil must be treated, stored and disposed of by the owner in accordance with applicable local, state and federal law.

In the event the gravel, soil cover, and/or impervious surfaces overlying the contaminated soil and groundwater are removed or replaced, the replacement barrier must be equally impervious. Any replacement barrier will be subject to the same maintenance and inspection guidelines as outlined in this Maintenance Plan unless indicated otherwise by the DNR or its successor.

The property owner, in order to maintain the integrity of the gravel, soil cover, and impervious surfaces, will maintain a copy of this Maintenance Plan at the site; or, if there is no acceptable place to keep it at the site (for example, no building is present), at the address of the property owner and make it available to all interested parties (i.e. on-site employees, contractors, future property owners, etc.) for viewing.

Prohibition of Activities and Notification of DNR Prior to Actions Affecting a Cover

The following activities are prohibited on any portion of the property where [pavement, a building foundation, soil cover, engineered cap or other barrier] is required as shown on the attached map, unless prior written approval has been obtained from the Wisconsin Department of Natural Resources: 1) removal of the existing barrier; 2) replacement with another barrier; 3) excavating or grading of the land surface; 4) filling on capped or paved areas; 5) plowing for agricultural cultivation; 6) construction or placement of a building or other structure; 7) changing the use or occupancy of the property to single-family residential use; or 8) changing the construction of a building that has a vapor mitigation system in place.

SOURCE PROPERTY

If removal, replacement or other changes to a cover, or a building which is acting as a cover, are considered, the property owner will contact DNR at least 45 days before taking such an action, to determine whether further action may be necessary to protect human health, safety, or welfare or the environment, in accordance with s. NR 727.07, Wis. Adm. Code.

Amendment or Withdrawal of Maintenance Plan

This Maintenance Plan can be amended or withdrawn by the property owner and its successors with the written approval of DNR.

Continuing Obligations Inspection and Maintenance Log

Form 4400-305 (R 7/20)

Directions: In accordance with s. NR 727.05 (1) (b) 3., Wis. Adm. Code, use of this form for documenting the inspections and maintenance of certain continuing obligations is required. Personal information collected will be used for administrative purposes and may be provided to requesters to the extent required by Wisconsin's Public Records law [ss. 19.31-19.39, Wis. Stats.]. When using this form, identify the condition that is being inspected. See the closure approval letter for this site for requirements regarding the submittal of this form to the Department of Natural Resources. A copy of this inspection log is required to be maintained either on the property, or at a location specified in the closure approval letter. Do NOT delete previous inspection results. This form was developed to provide a continuous history of site inspection results. The Department of Natural Resources project manager is identified in the closure letter. The project manager may also be identified from the database, BRRTS on the Web, at http://dnr.wi.gov/botw/SetUpBasicSearchForm.do, by searching for the site using the BRRTS ID number, and then looking in the "Who" section.

Activity (Site) Name	BRRTS No.

Kaukauna, WI 54130

SUBJECT: Final Case Closure with PAL Exemption by Closure Committee for **Ghost Town Fitness Center**, 180 Fox Shores Dr, Kaukauna, WI
WDNR BRRTS Activity #: 02-45-547911

Dear Mr. Eiting:

On October 3, 2006, the Northeast Regional Closure Committee reviewed the above referenced case for closure. This committee reviews environmental remediation cases for compliance with state laws and standards to maintain consistency in the closure of these cases.

On October 6, 2006, the Department received documentation for abandonment of the monitoring well, indicating that you have complied with the final requirements of closure. Based on the correspondence and data provided, it appears that your case has been remediated to Department standards in accordance with s. NR 726.05, Wis. Adm. Code. The Department considers this case closed and no further investigation, remediation or other action is required at this time.

Recent groundwater monitoring data at this site indicates exceedances of the NR 140 preventive action limit (PAL) for arsenic and selenium at monitoring well, MW-1, but compliance with the NR 140 enforcement standard. The Department may grant an exemption to a PAL for a substance of public health concern, other than nitrate, pursuant to s. NR 140.28(2)(b), Wis. Adm. Code, if all of the following criteria are met:

1. The measured or anticipated increase in the concentration of the substance will be minimized to the extent technically and economically feasible.

2. Compliance with the PAL is either not technically or economically feasible.

3. The enforcement standard for the substance will not be attained or exceeded at the point of standards application.

4. Any existing or projected increase in the concentration of the substance above the background concentration does not present a threat to public health or welfare.

Based on the information you provided, the Department believes that the above criteria have been or will be met. Therefore, pursuant to s. NR 140.28(2)(b), Wis. Adm. Code, an exemption to the PAL is granted for arsenic and selenium at MW-1. This letter serves as your exemption.

Please be aware that this case may be reopened pursuant to s. NR 726.09, Wis. Adm. Code, if additional information regarding site conditions indicates that contamination on or from the site poses a threat to public health, safety or welfare, or the environment.

If you have any questions regarding this letter, please contact me at the number below.

Sincerely,

Jennifer Borski

GIS Registry Checklist

Form 4400-245 (R 8/11)

This Adobe Fillable form is intended to provide a list of information that is required for evaluation for case closure. It is to be used in conjunction with Form 4400-202, Case Closure Request. The closure of a case means that the Department has determined that no further response is required at that time based on the information that has been submitted to the Department.

NOTICE: Completion of this form is mandatory for applications for case closure pursuant to ch. 292, Wis. Stats. and ch. NR 726, Wis. Adm. Code, including cases closed under ch. NR 746 and ch. NR 726. The Department will not consider, or act upon your application, unless all applicable sections are completed on this form and the closure fee and any other applicable fees, required under ch. NR 749, Wis. Adm. Code, Table 1 are included. It is not the Department's intention to use any personally identifiable information from this form for any purpose other than reviewing closure requests and determining the need for additional response action. The Department may provide this information to requesters as required by Wisconsin's Open Records law [ss. 19.31 - 19.39, Wis. Stats.].

BRRTS #: 03-45-001729 *(No Dashes)* PARCEL ID #: 323040200

ACTIVITY NAME: KAUKAUNA CTY - WASTE OIL COLLECTION SITE WTM COORDINATES: X: 657662 Y: 424330

CLOSURE DOCUMENTS (the Department adds these items to the final GIS packet for posting on the Registry)

- [X] **Closure Letter**
- [ ] **Maintenance Plan** (*if activity is closed with a land use limitation or condition (land use control) under s. 292.12, Wis. Stats.*)
- [ ] **Continuing Obligation Cover Letter** (for property owners affected by residual contamination and/or continuing obligations)
- [ ] **Conditional Closure Letter**
- [ ] **Certificate of Completion (COC)** (for VPLE sites)

SOURCE LEGAL DOCUMENTS

- [X] **Deed:** The most recent deed as well as legal descriptions, for the **Source Property** (where the contamination originated). Deeds for other, off-source (off-site) properties are located in the **Notification** section.
  Note: *If a property has been purchased with a land contract and the purchaser has not yet received a deed, a copy of the land contract which includes the legal description shall be submitted instead of the most recent deed. If the property has been inherited, written documentation of the property transfer should be submitted along with the most recent deed.*
- [ ] **Certified Survey Map:** A copy of the certified survey map or the relevant section of the recorded plat map *for those properties where the legal description in the most recent deed refers to a certified survey map or a recorded plat map.* (lots on subdivided or platted property (e.g. lot 2 of xyz subdivision)).

  Figure #: **Title:**
- [X] **Signed Statement:** A statement signed by the Responsible Party (RP), which states that he or she believes that the attached legal description accurately describes the correct contaminated property.

MAPS (meeting the visual aid requirements of s. NR 716.15(2)(h))

Maps must be no larger than 11 x 17 inches unless the map is submitted electronically.

- [X] **Location Map:** A map outlining all properties within the contaminated site boundaries on a U.S.G.S. topographic map or plat map in sufficient detail to permit easy location of all parcels. If groundwater standards are exceeded, include the location of all potable wells within 1200 feet of the site.
  Note: *Due to security reasons municipal wells are not identified on GIS Packet maps. However, the locations of these municipal wells must be identified on Case Closure Request maps.*

  Figure #: 1 **Title: Site Location Map**
- [X] **Detailed Site Map:** A map that shows all relevant features (buildings, roads, individual property boundaries, contaminant sources, utility lines, monitoring wells and potable wells) within the contaminated area. This map is to show the location of all contaminated public streets, and highway and railroad rights-of-way in relation to the source property and in relation to the boundaries of groundwater contamination exceeding a ch. NR 140 Enforcement Standard (ES), and/or in relation to the boundaries of soil contamination exceeding a Residual Contaminant Level (RCL) or a Site Specific Residual Contaminant Levels (SSRCL) as determined under s. NR 720.09, 720.11 and 720.19.

  Figure #: 2 **Title: Site Detail Map, Site Plan Prior to Remediation**
- [X] **Soil Contamination Contour Map:** For sites closing with residual soil contamination, this map is to show the location of all contaminated soil and a single contour showing the horizontal extent of each area of contiguous residual soil contamination that exceeds a Residual Contaminant Level (RCL) or a Site Specific Residual Contaminant Level (SSRCL)as determined under s. NR 720.09, 720.11 and 720.19.

  Figure #: 7 **Title: Estimated Extent of Contamination Exceeding RC:s in the Vadose and Smear Zones**

BRRTS #: 03-45-001729 ACTIVITY NAME: KAUKAUNA CTY - WASTE OIL COLLECTION SITE

MAPS (continued)

☒ **Geologic Cross-Section Map:** A map showing the source location and vertical extent of residual soil contamination exceeding a Residual Contaminant Level (RCL) or a Site Specific Residual Contaminant Level (SSRCL). If groundwater contamination exceeds a ch. NR 140 Enforcement Standard (ES) when closure is requested, show the source location and vertical extent, water table and piezometric elevations, and locations and elevations of geologic units, bedrock and confining units, if any.

Figure #: 4 **Title: Pre-Remedial Geologic Cross Section A-A'**

Figure #: **Title:**

☒ **Groundwater Isoconcentration Map:** For sites closing with residual groundwater contamination, this map shows the horizontal extent of all groundwater contamination exceeding a ch. NR140 Preventive Action Limit (PAL) and an Enforcement Standard (ES). Indicate the direction and date of groundwater flow, based on the most recent sampling data.
Note: *This is intended to show the total area of contaminated groundwater.*

Figure #: 6 **Title: Groundwater Contour Map**

☒ **Groundwater Flow Direction Map:** A map that represents groundwater movement at the site. If the flow direction varies by more then 20° over the history of the site, submit 2 groundwater flow maps showing the maximum variation in flow direction.

Figure #: 6 **Title: Ground-water Flow Direction**

Figure #: 5 **Title: Groundwater Elevation Contours**

TABLES (meeting the requirements of s. NR 716.15(2)(h)(3))

Tables must be no larger than 11 x 17 inches unless the table is submitted electronically. Tables must not contain shading and/or cross-hatching. The use of **BOLD** or *ITALICS* is acceptable.

☒ **Soil Analytical Table:** A table showing remaining soil contamination with analytical results and collection dates.
Note: This is one table of results for the contaminants of concern. Contaminants of concern are those that were found during the site investigation, that remain after remediation. It may be necessary to create a new table to meet this requirement.

Table #: 1,1, 2 **Title: Summary of Soil Analytical Results, Summary of Field Headspace Analysis, Summary of..**

☒ **Groundwater Analytical Table:** Table(s) that show the most recent analytical results and collection dates, for all monitoring wells and any potable wells for which samples have been collected.

Table #: 3, 1, 4 **Title: Summary of Laboratory Analysis Groundwater, Summary of GW Analytical Results**

☐ **Water Level Elevations:** Table(s) that show the previous four (at minimum) water level elevation measurements/dates from all monitoring wells. If present, free product is to be noted on the table.

Table #: **Title:**

IMPROPERLY ABANDONED MONITORING WELLS

For each monitoring well not properly abandoned according to requirements of s. NR 141.25 include the following documents.
Note: *If the site is being listed on the GIS Registry for only an improperly abandoned monitoring well you will only need to submit the documents in this section for the GIS Registry Packet.*

☒ **Not Applicable**

☐ **Site Location Map:** A map showing all surveyed monitoring wells with specific identification of the monitoring wells which have not been properly abandoned.
Note: *If the applicable monitoring wells are distinctly identified on the Detailed Site Map this Site Location Map is not needed.*

Figure #: **Title:**

☐ **Well Construction Report:** Form 4440-113A for the applicable monitoring wells.

☐ **Deed:** The most recent deed as well as legal descriptions for each property where a monitoring well was not properly abandoned.

☐ **Notification Letter:** Copy of the notification letter to the affected property owner(s).

BRRTS #: 03-45-001729 ACTIVITY NAME: KAUKAUNA CTY - WASTE OIL COLLECTION SITE

NOTIFICATIONS

Source Property

☒ **Not Applicable**

☐ **Letter To Current Source Property Owner:** If the source property is owned by someone other than the person who is applying for case closure, include a copy of the letter notifying the current owner of the source property that case closure has been requested.

☐ **Return Receipt/Signature Confirmation:** Written proof of date on which confirmation was received for notifying current source property owner.

Off-Source Property

Group the following information per individual property and label each group according to alphabetic listing on the "Impacted Off-Source Property" attachment.

☒ **Not Applicable**

☐ **Letter To "Off-Source" Property Owners:** Copies of all letters sent by the Responsible Party (RP) to owners of properties with groundwater exceeding an Enforcement Standard (ES), and to owners of properties that will be affected by a land use control under s. 292.12, Wis. Stats.
Note: *Letters sent to off-source properties regarding residual contamination must contain standard provisions in Appendix A of ch. NR 726.*

Number of "Off-Source" Letters:

☐ **Return Receipt/Signature Confirmation:** Written proof of date on which confirmation was received for notifying any off-source property owner.

☐ **Deed of "Off-Source" Property:** The most recent deed(s) as well as legal descriptions, for all affected deeded **off-source property(ies).** This does not apply to right-of-ways.
Note: *If a property has been purchased with a land contract and the purchaser has not yet received a deed, a copy of the land contract which includes the legal description shall be submitted instead of the most recent deed. If the property has been inherited, written documentation of the property transfer should be submitted along with the most recent deed.*

☐ **Certified Survey Map:** A copy of the certified survey map or the relevant section of the recorded plat map *for those properties where the legal description in the most recent deed refers to a certified survey map or a recorded plat map.* (lots on subdivided or platted property (e.g. lot 2 of xyz subdivision)).

Figure #: **Title:**

☐ **Letter To "Governmental Unit/Right-Of-Way" Owners:** Copies of all letters sent by the Responsible Party (RP) to a city, village, municipality, state agency or any other entity responsible for maintenance of a public street, highway, or railroad right-of-way, within or partially within the contaminated area, for contamination exceeding a groundwater Enforcement Standard (ES) and/or soil exceeding a Residual Contaminant Level (RCL) or a Site Specific Residual Contaminant Level (SSRCL).

Number of "Governmental Unit/Right-Of-Way Owner" Letters:

SUBJECT: Final Case Closure By Project Manager, Deed Restriction Filed
Kaukauna City - Waste Oil Site, 222 West 3rd St. Kaukauna, WI

Dear Mr. Van Berkel:

Your site as described above was reviewed for closure by the Department of Natural Resources. The Department reviews environmental remediation cases for compliance with state laws and standards to maintain consistency in the closure of these cases.

On July 29, 2003, the Department received correspondence indicating that you have complied with the conditions of closure. The soil and groundwater deed restrictions were filed on May 20, 2003. Based on the correspondence and data provided, it appears that your case meets the screening criteria of s. NR 746.07, and the requirements of ch. NR 726, Wis. Adm. Code. The Department considers this case closed and no further investigation, remediation or other action is required at this time.

Your site will be listed on the DNR Remediation and Redevelopment GIS Registry of Closed Remediation Sites. Information that was submitted with your closure request application will be included on the registry. To review the sites on the GIS Registry web page, visit
http://gomapout.dnr.state.wi.us/org/at/et/geo/gwur/index.htm

If this is a PECFA site, section 101.143, Wis. Stats., requires that PECFA claimants seeking reimbursement of interest costs, for sites with petroleum contamination, submit a final reimbursement claim within 120 days after they receive a closure letter on their site. For claims not received by the PECFA Program within 120 days of the date of this letter, interest costs after 60 days of the date of this letter will not be eligible for PECFA reimbursement.

Please be aware that this case may be reopened pursuant to s. NR 726.09, Wis. Adm. Code, if additional information regarding site conditions indicates that contamination on or from the site poses a threat to public health, safety or welfare, or the environment. The Department appreciates your efforts to restore the environment at this site. If you have any questions regarding this letter, please contact me at 920-303-5435.

Sincerely,

Cheryl Laatsch
Hydrogeologist

Declaration of Restrictions

In Re: The parcel of property described in No. 4 of Exhibit A (Warranty Deed) hereby attached and made a part of this restriction.

Recording Area

Name and Return Address
Paul Van Berkel
Attorney, City of Kaukauna
180 West Wisconsin Avenue
Kaukauna, WI 54130

pd 27.00

STATE OF WISCONSIN)
) ss
COUNTY OF OUTAGAMIE)

32-3-0402-00
Parcel Identification Number (PIN)

WHEREAS, the City of Kaukauna is the owner of the above-described property.

WHEREAS, one or more petroleum discharges have occurred on this property. Petroleum contaminated groundwater above ch. NR 140, Wis. Adm. Code enforcement standards existed on this property at the following location(s) on the following date(s): monitoring well 4 (MW-4) benzene was 260 micrograms per liter on November 29, 1999, and iron was 10 milligrams per liter on April 8, 1999; monitoring well 1 (MW-1) iron was 10 milligrams per liter on April 8, 1999 and soil contamination existed on the property at the following location(s) on the following date(s): Soil boring 6 (B-6) with 150 milligrams per kilogram (mg/kg) lead at 1 to 3 feet, B-9 with 370 mg/kg lead, 1500 micrograms per kilogram (ug/kg) benzene, 11190 ug/kg xylene at 1-3 feet on April 15, 1998 and B15 with 2200 mg/kg gasoline range organics (GRO) ethylbenzene, 3500 mg/kg diesel range organics (DRO), 13000 ug/kg benzene, 54000 ug/kg ethylbenzene, 3500 ug/kg toluene and 166800 ug/kg xylene at 2.5 to 4.5 feet on August 28, 1998.

Location of monitoring wells and soil borings are provided on Exhibit B, (Figure 3), hereby attached and made part of this restriction.

WHEREAS, it is the desire and intention of the property owner to impose on the property restrictions which will make it unnecessary to conduct further groundwater or soil remediation activities on the property at the present time.

WHEREAS, natural attenuation has been approved by the Department of Natural Resources to remediate groundwater contamination exceeding ch. NR 140, Wis. Adm. Code groundwater standards within the boundaries of this property.

WHEREAS, construction of wells where the water quality does not comply with drinking water standards in ch. NR 809, Wis. Adm. Code is restricted by chs. NR 811 and NR 812, Wis. Adm. Code. Special well construction standards or water treatment requirements, or both, or well construction prohibitions may apply.

NOW THEREFORE, the owner hereby declares that all of the property described above is held and shall be held, conveyed or encumbered, leased, rented, used, occupied and improved subject to the following limitation and restrictions:

Anyone who proposes to construct or reconstruct a well on this property is required to contact the Department of Natural Resources' Bureau of Drinking Water and Groundwater, or it successor agency, to determine what specific requirements are applicable, prior to constructing or reconstructing a well on this property. No well may be constructed on this property unless applicable requirements are met.

The following activities are prohibited on that portion of the property above described in Exhibit C, where a cap or cover has been placed as identified in Exhibit B (Figure 3), unless prior written approval has been obtained from the Wisconsin Department of Natural Resources or its successor or assign: (1) Excavating or grading of the land surface; (2) Filling on the capped area; (3) Plowing for agricultural cultivation; and (4) Construction or installation of a building of other structure with a foundation that would sit on or be places within a cap or cover. In addition, the cap or cover shall be maintained in compliance with a plan prepared and submitted to the Wisconsin Department of Natural Resources by a responsible party, as required by section NR 724.13 (2), Wis. Adm. Code (1999).

This restriction is hereby declared to be a covenant running with the land and shall be fully binding upon all persons acquiring the above-described property whether by descent, devise, purchase or otherwise. This restriction benefits and is enforceable by the Wisconsin Department of Natural Resources, its successors or assigns. The Department, its successors or assigns, may initiate proceedings at law or in equity against any person or persons who violate or are proposing to violate this covenant, to prevent the proposed violation or to recover damages for such violation.

Any person who is or becomes owner of the property described above may request that the Wisconsin Department of Natural Resources or its successor issue a determination that one or more of the restrictions set forth in this covenant is no longer required. Upon the receipt of such a request, the Wisconsin Department of Natural Resources shall determine whether or not the restrictions contained herein can be extinguished. If the Department determines that the restrictions can be extinguished, an affidavit, attached to

a copy of the Department's written determination, may be recorded to give notice that this deed restriction, or portions of this deed restriction, are no longer binding.

By Signing the document, John J. Lambie, Mayor, and Susan J. Duda, Clerk/Treasurer, assert that they are duly authorized to sign this document on behalf of the City of Kaukauna.

IN WITNESS WHEREOF, the owner of the property has executed this Declaration of Restrictions, this 13th day of May, 2003.

Signature: John J. Lambie
Printed Name: John J. Lambie
Title: Mayor

Signature: Susan J Duda

WARRANTY DEED VOL 957 PAGE 71

THIS INDENTURE, made by BADGER NORTHLAND INC., also known as BADGER NORTHLAND, INC., a Corporation duly organized and existing under and by virtue of the laws of the State of Delaware, formerly known as M-F Badger Corporation, a Delaware Corporation, located at Kaukauna, Wisconsin, Outagamie County, Grantor, of the City of Kaukauna, Outagamie County, Wisconsin, hereby conveys and warrants to the CITY OF KAUKAUNA, a Wisconsin Municipal Corporation, Grantee, of the City of Kaukauna, Outagamie County, Wisconsin, for valuable consideration of $447,000, and other good and valuable consideration, the following tracts of land located in Outagamie County, State of Wisconsin:

1. All of Lots 1 through 16, in Block eight (8), of LEDYARD PLAT, and all that portion of the vacated alley located in Block 8, LEDYARD PLAT, abutting upon Lots 5 through 12, inclusive, on Second Street and upon Lots 13 through 16, inclusive, on Third Street, said vacated alley being a parcel of land 20 feet wide and 200 feet long, all according to the recorded Assessor's Plat of the City of Kaukauna, Outagamie County, Wisconsin.

2. That part of Lot "A" Ledyard Plat of the City of Kaukauna, bounded and described as follows: Commencing at the most Westerly corner of Block 8 of aforesaid Ledyard Plat, being a point on the Northeasterly line of Third Street; thence Northwesterly along said Northeasterly line of Third Street, a distance of 723.5 feet to a point distant 25 feet Southerly, measured radially, from the center line of the Main track of the Chicago and North Western Railway Company, as said main track is now located; thence Easterly along a line parallel with said main track center line, said parallel line being a curved line concave to the South and having a radius of 810.00 feet (the long chord of which forms an angle of $24^{\circ}32'$ as measured from Southeast to East, with the Northeasterly line of Third Street and has a length of 226.7 feet) a distance of 227.45 feet to the point of beginning of the parcel of land herein described; thence Easterly along a curved line convex to the South and having a radius of 920 feet (the chord of which forms an angle of $14^{\circ}20'$ to the right of an extension Easterly, of the long chord of the last described curve and has a length of 289.9 feet) a distance of 291.11 feet; thence Easterly along a straight line which forms an angle of $8^{\circ}10'$ to the left of an extension, Easterly of the long chord of the last described curve, a distance of 237 feet, more or less, to an intersection with the Southwesterly line of Second Street extended Northwesterly; thence Southeasterly along the extension of said Southwesterly line of Second Street, a distance of 6.8 feet, more or less, to the most Northerly corner of aforesaid Block 8, Ledyard Plat; thence Northeasterly along the Northeasterly extension of the Northwesterly line of said Block 8, a distance of 45 feet, more or less, to a point distant 25 feet Southwesterly, measured at right angles, from the center line of the main track of the Chicago and North Western Railway Company aforesaid; thence Northwesterly along a line parallel with said main track center line, a distance of 520 feet, more or less,

EXHIBIT A PAGE 2

to the point of beginning. (The above described premises located in the unplatted part of Ledyard Plat according to the recorded Assessor's Plat of the City of Kaukauna, Outagamie County, Wisconsin, excepting and reserving unto the Chicago and Northwestern Railroad Company, a Wisconsin corporation, the right to maintain, operate, use, reconstruct and replace any and all existing conduits, sewers, water mains, gas lines, electric power lines, communication lines, wires and other utilities upon said premises.

3. A part of Lot "B" in the Plat of Ledyard, now a part of the City of Kaukauna, bounded and described as follows: Commencing at the point of intersection of the Northwesterly line of Fourth Avenue (State Trunk Highway 55) and the Northeasterly line of Second Street; thence Northwesterly along said Northeasterly line of Second Street, a distance of 215 feet to the point of beginning of the parcel of land herein described; thence Northeasterly along a line at right angles to said Northeasterly line of Second Street, a distance of 110 feet, more or less, to a point distant 32 feet Southwesterly, measured at right angles, from the center line of the main track of the Chicago and North Western Railway Company, as said main track is now located; thence Southwesterly along a straight line, a distance of 335 feet, more or less, to a point on the Northeasterly line of Second Street aforesaid, distant 35 feet Southwesterly, measured at right angles, from said main track center line; thence Southeasterly along said Northeasterly line of Second Street, a distance of 315 feet, more or less, less and excepting that property conveyed by Badger Northland Inc. to the City of Kaukauna by Warranty Deed dated September 29, 1972, for road purposes. The above described premises located in the unplatted part of Ledyard Plat according to the recorded Assessor's Plat of the City of Kaukauna, Outagamie County, Wisconsin. Less and excepting a reservation unto the prior grantor, Chicago and Northwestern Railway Company, a Wisconsin corporation, for its right to maintain, operate, use, reconstruct and replace any and all existing conduits, sewers, water mains, gas lines, electric power lines, communication lines, wires and other utilities upon the premises.

4. That part of Lot "A" Ledyard Plat of the City of Kaukauna, Outagamie County and State of Wisconsin, described as follows, to-wit: Beginning at the most Westerly corner of Block 8 of aforesaid Ledyard Plat; thence Northwesterly along the Northeasterly line of Third Street, a distance of 723.5 feet to a point distant 25 feet Southerly, measured radially, from the center line of the main track of the Chicago and North Western Railway Company as said main track is now located and established; thence Easterly along a line parallel with the center line of said main track, said line being a curved line concave to the South and having a radius of 810.00 feet (the long chord of which forms an angle of 24°32', as measured from Southeast to East, with the Northeasterly line of Third Street and has a length of 226.7 feet) a distance of 227.45 feet, thence Easterly along a curved line convex to the South and having a radius of 920.00 feet (the long chord of which forms an angle of 14°20' to the right of an extension Easterly, of the long chord of the last described curve and has a length of 289.9 feet) a distance of 291.11 feet; thence Easterly along a straight line which forms an angle of 8°10' to the left of an extension, Easterly, of the long chord

S/A 1st Desc. in V763 P473

EXHIBIT A PAGE 3

of the last described curve, a distance of 237.0 feet, more or less, to an intersection with the Southwesterly line of Second Street extended Northwesterly; thence Southeasterly along the extension of said line of Second Street, a distance of 6.8 feet, more or less, to the most Northerly corner of aforesaid Block 8, Ledyard Plat; thence Southwesterly along the Northwesterly line of said Block 8, a distance of 220.0 feet, more or less, to the point of beginning, (said premises being located in the unlotted part of Ledyard Plat according to the recorded Assessor's Plat of said City). Subject to the rights of the City of Kaukauna under a lease to construct, maintain and use a water line, as it presently exists, in such real estate.

FEE
2
EXEMPT

Except for easements, covenants and restrictions of record, and covenants for any public roadway purposes.

Exempt from Real Estate Transfer Return and transfer tax, Exempt # 2.

IN WITNESS WHEREOF, the said grantor corporation has caused these presents to be signed by Gail E. Janssen, its corporation president and countersigned by Kenneth B. Myers, its corporation secretary, at Kaukauna, Wisconsin, and its corporate seal hereunto affixed this 26th day of July, 1974.

SUBJECT: Closure - Kaukauna City Waste Oil Site,
WDNR BRRTS ID #:03-45-001729

Dear Mr. Sundelius:

On December 16, 1999 the Department received your Addendum to Case Closure Request. After review the Department feels that the site meets the requests of the additional word described in the letter sent on November 10,1999.

- Soil contamination at boring location B-3 (MW-1) must be further investigated for direct contact concerns.

- A minimum of one additional round of groundwater samples analyzed for PVOC and naphthalene to evaluate post remediation contaminant trend.

Please complete the attached restriction and return a draft to this office for approval with a copy of the deed/legal description, survey map if available and a site map showing the contaminated groundwater locations. Pending Department approval the restrictions can be filed with the Outagamie County Register of Deeds. Only when the Department has received documentation that the restriction has been filed with County Register of Deeds Office and the monitoring wells abandoned according to the requirements of NR 141 Wis. Adm. Code, will the Department consider the site closed.

If you have any questions, please contact Greg Tilkens at (920) 492-5868 or Scott C. Miller at (920) 492-5871.

Sincerely,

Scott C. Miller
Hydrogeologist

WARRANTY DEED

Vol 57 Pg 71

THIS INDENTURE, made by BADGER NORTHLAND INC., also known as BADGER NORTHLAND, INC., a Corporation duly organized and existing under and by virtue of the laws of the State of Delaware, formerly known as M-F Badger Corporation, a Delaware Corporation, located at Kaukauna, Wisconsin, Outagamie County, Grantor, of the City of Kaukauna, Outagamie County, Wisconsin, hereby conveys and warrants to the CITY OF KAUKAUNA, a Wisconsin Municipal Corporation, Grantee, of the City of Kaukauna, Outagamie County, Wisconsin, for valuable consideration of $447,000, and other good and valuable consideration, the following tracts of land located in Outagamie County, State of Wisconsin:

1. All of Lots 1 through 16, in Block eight (8), of LEDYARD PLAT, and all that portion of the vacated alley located in Block 8, LEDYARD PLAT, abutting upon Lots 5 through 12, inclusive, on Second Street and upon Lots 13 through 16, inclusive, on Third Street, said vacated alley being a parcel of land 20 feet wide and 200 feet long, all according to the recorded Assessor's Plat of the City of Kaukauna, Outagamie County, Wisconsin.

2. That part of Lot "A" Ledyard Plat of the City of Kaukauna, bounded and described as follows: Commencing at the most Westerly corner of Block 8 of aforesaid Ledyard Plat, being a point on the Northeasterly line of Third Street; thence Northwesterly along said Northeasterly line of Third Street, a distance of 723.5 feet to a point distant 25 feet Southerly, measured radially, from the center line of the Main track of the Chicago and North Western Railway Company, as said main track is now located; thence Easterly along a line parallel with said main track center line, said parallel line being a curved line concave to the South and having a radius of 810.00 feet (the long chord of which forms an angle of 24°32' as measured from Southeast to East, with the Northeasterly line of Third Street and has a length of 226.7 feet) a distance of 227.45 feet to the point of beginning of the parcel of land herein described: thence Easterly along a curved line convex to the South and having a radius of 920 feet (the chord of which forms an angle of 14°20' to the right of an extension Easterly, of the long chord of the last described curve and has a length of 289.9 feet) a distance of 291.11 feet: thence Easterly along a straight line which forms an angle of 8°10' to the left of an extension, Easterly of the long chord of the last described curve, a distance of 237 feet, more or less, to an intersection with the Southwesterly line of Second Street extended Northwesterly; thence Southeasterly along the extension of said Southwesterly line of Second Street, a distance of 6.8 feet, more or less, to the most Northerly corner of aforesaid Block 8, Ledyard Plat: thence Northeasterly along the Northeasterly extension of the Northwesterly line of said Block 8, a distance of 43 feet, more or less, to a point distant 25 feet Southwesterly, measured at right angles, from the center line of the main track of the Chicago and North Western Railway Company aforesaid: thence Northwesterly along a line parallel with said main

to the point of beginning. (The above described premises located in the unplatted part of Ledyard Plat according to the recorded Assessor's Plat of the City of Kaukauna, Outagamie County, Wisconsin, excepting and reserving unto the Chicago and Northwestern Railroad Company, a Wisconsin corporation, the right to maintain, operate, use, reconstruct and replace any and all existing conduits, sewers, water mains, gas lines, electric power lines, communication lines, wires and other utilities upon said premises.

3. A part of Lot "B" in the Plat of Ledyard, now a part of the City of Kaukauna, bounded and described as follows: Commencing at the point of intersection of the Northwesterly line of Fourth Avenue (State Trunk Highway 55) and the Northeasterly line of Second Street; thence Northwesterly along said Northeasterly line of Second Street, a distance of 215 feet to the point of beginning of the parcel of land herein described; thence Northeasterly along a line at right angles to said Northeasterly line of Second Street, a distance of 110 feet, more or less, to a point distant 32 feet Southwesterly, measured at right angles, from the center line of the main track of the Chicago and North Western Railway Company, as said main track is now located; thence Southwesterly along a straight line, a distance of 335 feet, more or less, to a point on the Northeasterly line of Second Street aforesaid, distant 35 feet Southwesterly, measured at right angles, from said main track center line; thence Southeasterly along said Northeasterly line of Second Street, a distance of 315 feet, more or less, less and excepting that property conveyed by Badger Northland Inc. to the City of Kaukauna by Warranty Deed dated September 29, 1972, for road purposes. The above described premises located in the unplatted part of Ledyard Plat according to the recorded Assessor's Plat of the City of Kaukauna, Outagamie County, Wisconsin. Less and excepting a reservation unto the prior grantor, Chicago and Northwestern Railway Company, a Wisconsin corporation, for its right to maintain, operate, use, reconstruct and replace any and all existing conduits, sewers, water mains, gas lines, electric power lines, communication lines, wires and other utilities upon the premises.

4. That part of Lot "A" Ledyard Plat of the City of Kaukauna, Outagamie County and State of Wisconsin, described as follows, to-wit: Beginning at the most Westerly corner of Block 8 of aforesaid Ledyard Plat; thence Northwesterly along the Northeasterly line of Third Street, a distance of 723.5 feet to a point distant 25 feet Southerly, measured radially, from the center line of the main track of the Chicago and North Western Railway Company as said main track is now located and established; thence Easterly along a line parallel with the center line of said main track, said line being a curved line concave to the South and having a radius of 810.00 feet (the long chord of which forms an angle of $24^{\circ}32'$, as measured from Southeast to East, with the Northeasterly line of Third Street and has a length of 226.7 feet) a distance of 227.45 feet, thence Easterly along a curved line convex to the South and having a radius of 920.00 feet (the long chord of which forms an angle of $14^{\circ}20'$ to the right of an extension Easterly, of the long chord of the last described curve and has a length of 289.9 feet) a distance of 291.11 feet; thence Easterly along a straight line which forms an angle of $8^{\circ}10'$ to the left of an extension, Easterly, of the long chord

of the last described curve, a distance of 237.0 feet, more or less, to an intersection with the Southwesterly line of Second Street extended Northwesterly; thence Southeasterly along the extension of said line of Second Street, a distance of 6.8 feet, more or less, to the most Northerly corner of aforesaid Block 8, Ledyard Plat; thence Southwesterly along the Northwesterly line of said Block 8, a distance of 220.0 feet, more or less, to the point of beginning, (said premises being located in the unlotted part of Ledyard Plat according to the recorded Assessor's Plat of said City). Subject to the rights of the City of Kaukauna under a lease to construct, maintain and use a water line, as it presently exists, in such real estate.

FEE EXEMPT # 2

Except for easements, covenants and restrictions of record, and covenants for any public roadway purposes.

Exempt from Real Estate Transfer Return and transfer tax, Exempt # 2.

IN WITNESS WHEREOF, the said grantor corporation has caused these presents to be signed by Gail E. Janssen, its corporation president and countersigned by Kenneth B. Myers, its corporation secretary, at Kaukauna, Wisconsin, and its corporate seal hereunto affixed this 26th day of July, 1974.

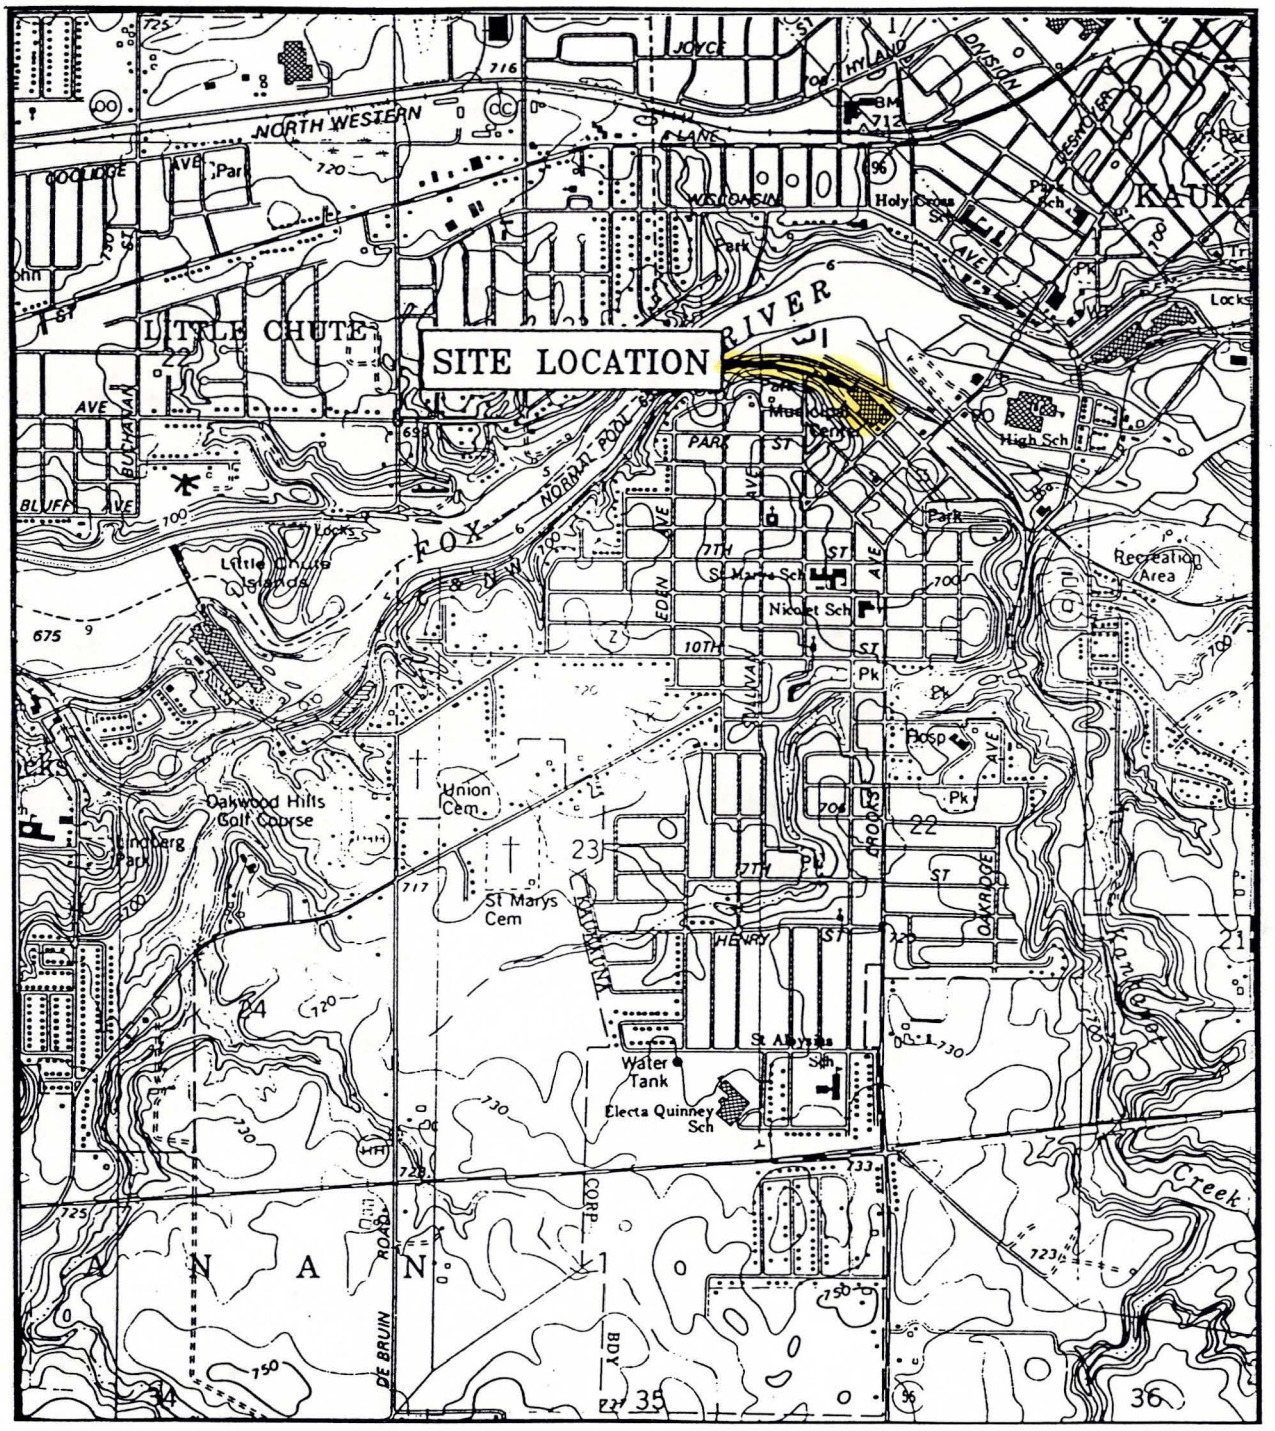
Oshkosh, WI 54901-9731

Re: Soil and Groundwater Restrictions – City of Kaukauna Lands

Dear Ms. Laatsch:

I am told you want a statement from me that the legal description in the recorded Deed Restriction, a copy of which I previously forwarded to you on June 23rd, 2003, is correct. It is, in fact, correct.

The Common Council of the City of Kaukauna passed a resolution on May 6th, 2003, approving and accepting the deed restrictions using the same legal description based on my representation that they were accurate.



Attorney Renville of your department and I had exchanged correspondence on several occasions to clarify and establish the proper legal description to use in this Deed Restriction.

I trust that the foregoing meets your requirements. If not, please speak to me directly so that I may better understand what you need.

Sincerely yours,

Paul Van Berkel
City Attorney

TABLE 1
SUMMARY OF FIELD HEADSPACE ANALYSIS
SOIL BORING SAMPLES
CONCENTRATION IN PPM (ISOBUTYLENE EQUIVALENTS)
MARCH 21, 1994, SAMPLING EVENT

SAMPLE ID	SAMPLE LOCATION	DEPTH (FEET)	PID	SOIL CHARACTERISTICS
B1–1	Boring B1	2.0 – 4.0	4.0	Black silt with gravel fill. Slight odor?
* B1–2		4.0 – 6.0	10.0	Brown sand with silt and gravel. No odor.
B1–3		6.0 – 8.0	10.0	Brown clay. No odor.
B1–4		8.0 – 10.0	5.0	Brown clay with gravel.
B2–1	Boring B2	2.0 – 4.0	4.0	Brown silt with some gravel and cinders. No odor.
B2–2		4.0 – 6.0	3.0	Brown clay with gravel. No odor.
* B2–3		6.0 – 8.0	3.0	Brown clay with gravel. No odor.
B2–4		8.0 – 10.0	3.0	Tight red brown clay with no gravel. No odor.
B3–1	Monitoring Well MW1	2.0 – 4.0	1000	Black silt (fill) with cinders and gravel. Solvent/paint odor
* B3–2		4.0 – 6.0	93.0	Brown clay with some tan sand and gravel. No odor.
B3–3		6.0 – 8.0	3.0	Brown clay with gravel. No odor.
B3–4		8.0 – 10.0	1.0	Brown clay with gravel. No odor.
B4–1	Boring B4	2.0 – 4.0	0.0	Black silt with cinders (fill) and gravel. No odor.
B4–2		4.0 – 6.0	111	Clay with gravel and sand. Waste oil odor at tip.
* B4–3		6.0 – 8.0	15.0	Clay with gravel and sand. Some waste oil odor to 7 feet.
B4–4		8.0 – 10.0	0.0	Red brown clay. No odor.
B5–1	Boring B5	1	0.0	Silt with sand. No odor.
* B5–2		2.0 – 4.0	0.0	Silt with some gravel. No odor.
B5–3		4.0 – 6.0	0.0	Silt with wood organics. No odor.
B5–4		6.0 – 8.0	0.0	Silt. No odor.

* = sample sent in for laboratory analysis

TABLE 2
SUMMARY OF LABORATORY ANALYSIS
SOIL BORING SAMPLES
MARCH 21, 1994 SAMPLING EVENT

PARAMETER	GUIDE	B1-2	B2-3	B3-2	B4-3	B5-2

SUBJECT: Final Case Closure By Project Manager, Deed Restriction Filed
Kaukauna City - Waste Oil Site, 222 West 3rd St. Kaukauna, WI

Dear Mr. Van Berkel:

Your site as described above was reviewed for closure by the Department of Natural Resources. The Department reviews environmental remediation cases for compliance with state laws and standards to maintain consistency in the closure of these cases.

On July 29, 2003, the Department received correspondence indicating that you have complied with the conditions of closure. The soil and groundwater deed restrictions were filed on May 20, 2003. Based on the correspondence and data provided, it appears that your case meets the screening criteria of s. NR 746.07, and the requirements of ch. NR 726, Wis. Adm. Code. The Department considers this case closed and no further investigation, remediation or other action is required at this time.

Your site will be listed on the DNR Remediation and Redevelopment GIS Registry of Closed Remediation Sites. Information that was submitted with your closure request application will be included on the registry. To review the sites on the GIS Registry web page, visit http://gomapout.dnr.state.wi.us/org/at/et/geo/gwur/index.htm

If this is a PECFA site, section 101.143, Wis. Stats., requires that PECFA claimants seeking reimbursement of interest costs, for sites with petroleum contamination, submit a final reimbursement claim within 120 days after they receive a closure letter on their site. For claims not received by the PECFA Program within 120 days of the date of this letter, interest costs after 60 days of the date of this letter will not be eligible for PECFA reimbursement.

Please be aware that this case may be reopened pursuant to s. NR 726.09, Wis. Adm. Code, if additional information regarding site conditions indicates that contamination on or from the site poses a threat to public health, safety or welfare, or the environment. The Department appreciates your efforts to restore the environment at this site. If you have any questions regarding this letter, please contact me at 920-303-5435.

Sincerely,

Cheryl Laatsch

Re: Soil and Groundwater Restrictions – City of Kaukauna Lands

Dear Ms. Laatsch:

I am told you want a statement from me that the legal description in the recorded Deed Restriction, a copy of which I previously forwarded to you on June 23rd, 2003, is correct. It is, in fact, correct.

The Common Council of the City of Kaukauna passed a resolution on May 6th, 2003, approving and accepting the deed restrictions using the same legal description based on my representation that they were accurate.

Attorney Renville of your department and I had exchanged correspondence on several occasions to clarify and establish the proper legal description to use in this Deed Restriction.

I trust that the foregoing meets your requirements. If not, please speak to me directly so that I may better understand what you need.

Sincerely yours,

Paul Van Berkel
City Attorney

Subject: FW: Deed Restriction

Hi Joe -

I have a deed restriction that I sent to the City of Kaukauna for signing. They are have concerns about the restriction. I have attached the restriction that was sent to them. It is my understanding that this was approved sometime in 2000...? I have attached it for your review and will fax the map to your attention. The City Attorney has some questions about the figure. I was advised by fellow OSH staff that they could have the restriction on a specific portion of the property, but that we would need a certified legal description of that portion.

Please advise as to how to proceed. I can give the attorney your name and phone, or you can call the directly.

Thanks
Cheryl

Cheryl:

The City of Kaukauna's Attorney, Mr. Paul VanBerkel, would like discuss the above referenced deed restriction with your legal staff. His concern remains with the vaugness of Figure 3 referenced in the deed restriction.

Please have your legal staff contact him or forward me the contact information and I will get it to Mr. VanBerkel.

He can be reached at:

180 W. Wisconsin Ave
Kaukauna, WI 54130

Reduced From
11 inches x 17 inches

~~4~~ 9-00

With additional info (Fischer rpt – 12-13-99) closure of the site was acceptable (Miller ltr – 1-19-00) however, the Miller letter only asks for a ground water use restriction, it should of asked for a soil deed restriction and ground water use rest (see closure committee comments on 11-8-99 closure package). In addition, Fischer's draft ground water use rest. (2-11-00) is not acceptable since it only describes a small portion of the entire property which does not include the entire ground water contamination plume. In February '00 I discussed this with Karen Burkman, we decided that I would draft the deed rest. to include the soil rest. language and she would supply me with a description of a portion of the entire property that included the plume (the area highlighted in Fischer's draft rest. plus the area of the Municipal building also shown in Fischer's draft rest.). Attached to this page is a disk that includes a deed restriction for the site. In it the appropriate property description must be inserted.

Another issue is that the closure committee states that a "soil deed restriction" must be filed for the contaminated soil that remains. The soil that remains is shallow (<4 ft) and exceeds our Pb RCL and in one sample the COMM 46 benzene direct contact number in another. I think there should be an institutional control deed rest. filed for the site which requires the maintenance of the asphalt over the contaminated soil. The attached rest. on the disk is written to be an institutional control rest. and ground water use rest. If you (whoever you is :-) think a general soil rest. is OK, then change the restriction.

Subject: **Deed Restriction for Kaukauna City Waste Oil Site, Kaukauna, WI**
WDNR BRRTS #03-45-001729

Dear Ms. Laatsch:

This letter is in response to your June 27, 2002, correspondence that included a deed restriction to be signed and recorded.

The City of Kaukauna had sent Mr. Greg Tilkens, Wisconsin Department of Natural Resources, a groundwater use restriction that we intended to file. I am not sure if your June letter is in response to our February 2000, letter to Mr. Tilkens or if the original correspondence was lost.

I am enclosing copies of all the information sent along with the February 2000, letter. I request that the enclosed deed restriction be the one recorded as it has already received City Council approval and includes the restrictions requested by the DNR at that time.

Please feel free to contact me with any questions or comments you may have.

Sincerely,

John Sundelius

RE: GROUNDWATER USE RESTRICTION for Kaukauna Maintenance Garage, 222 West 3rd Street, Kaukauna, WI
FISCHER #398132.003
WDNR # 03-45-1729
PECFA #54130-2406-22

Dear Mr. Tilkens:

On behalf of the City of Kaukauna, FISCHER is submitting the enclosed draft groundwater use restriction, including attachments. Also enclosed is the most recent warranty deed on file with the Outagamie County Registrar of Deeds Office. Please note that the legal description on the deed is for the entire large parcel owned by the City. The City of Kaukauna provided the legal description representative of the area where groundwater contamination above enforcement standards still remains, and FISCHER inserted that legal description into the restriction.

Please review the enclosures and notify FISCHER if the restriction is acceptable to the Wisconsin Department of Natural Resources. Upon notification, the restriction will be finalized and filed with the Outagamie County Registrar of Deeds Office.

If you have questions or require additional information, please contact me at (920) 766-2069.

Sincerely,

FISCHER

RESOLUTION NO. 3141

RESOLUTION AUTHORIZING A WELL RESTRICTION ON CERTAIN CITY OWNED LAND IN LIEU OF FURTHER REMEDIATION ACTIVITY

WHEREAS, certain lands surrounding the fueling island adjacent to the Street Department in the Municipal Services Building have sustained some petroleum and/or lead contamination; and,

WHEREAS, remediation efforts have been completed and any remaining contamination will be naturally attenuated as approved by the Wisconsin Department of Natural Resources; and,

WHEREAS, restrictions within Wisconsin Administrative Code limit the construction of wells where certain contamination exists in the soils and the said restrictions would currently apply to the lands described below; and,

WHEREAS, it is a condition of the permission from the Wisconsin Department of Natural Resources for the use of natural attenuation that a restriction prohibiting the construction of any well upon the lands described below must be recorded with the Register of Deeds Office;

NOW, THEREFORE, BE IT RESOLVED by the Common Council of the City of Kaukauna, that the Mayor and Clerk/Treasurer are hereby authorized to execute and have recorded the attached Groundwater Use Restriction Declaration for land described as follows:

> A parcel of land located in part of Lot "A", Ledyard Plat, City of Kaukauna, State of Wisconsin, further described as follows: Commencing at the southwest corner of Lot 13, Block Eight (8), Ledyard Plat, said point also being on the northerly Right of Way line of Third Street; also the point of beginning; thence northwesterly along the northerly Right of Way line of Third Street 200 feet; thence northeasterly along a line perpendicular to said Right of Way line a distance of 78 feet; thence southeasterly along a line parallel to said Right of Way line a distance of 200 feet; thence southwesterly along the northwesterly line of Lot 13, Block 8, Ledyard Plat a distance of 78 feet to the point of beginning.

Introduced and adopted this 15th day of February, 2000.

APPROVED: John J. Lambie

COUNTY OF Outagamie)[County where this document is signed]

WHEREAS, the City of Kaukauna is the owner of the above-described property.

WHEREAS, one or more petroleum discharges have occurred on this property. Petroleum-contaminated groundwater above ch. NR 140, Wis. Adm. Code enforcement standards existed on this property on November 29, 1999 at the location of monitoring well MW-4 [benzene was detected at 260 micrograms per liter (ug/l)]. The area of groundwater contamination with contaminant concentrations exceeding ch. NR 140, Wis. Adm. Code enforcement standards is estimated on Attachment 1. One soil sample collected from the vadose zone from three feet below ground surface from the north sidewall of the final excavation had a lead concentration of 110 milligrams per kilogram (mg/kg) on February 24, 1999. The area of soil contamination in the vadose zone on the property with a lead concentration exceeding the ch. NR 720, Wis. Adm. Code residual contaminant level is estimated on Attachment 2. Attachments 1 and 2 are made part of this restriction.

WHEREAS, it is the desire and intention of the property owner to impose on the property restrictions which will make it unnecessary to conduct further groundwater or soil remediation activities on the property at the present time.

WHEREAS, natural attenuation has been approved by the Department of Natural Resources to remediate groundwater contamination exceeding ch. NR 140, Wis. Adm. Code groundwater standards within the boundaries of this property.

WHEREAS, construction of wells where the water quality does not comply with drinking water standards in ch. NR 809, Wis. Adm. Code is restricted by chs. NR 811 and NR 812, Wis. Adm. Code. Special well construction standards or water treatment requirements, or both, or well construction prohibitions may apply.

NOW THEREFORE, the owner hereby declares that all of the property described above is held and shall be held, conveyed or encumbered, leased, rented, used, occupied and improved subject to the following limitation and restrictions:

> Anyone who proposes to construct or reconstruct a well on this property is required to contact the Department of Natural Resources' Bureau of Drinking Water and Groundwater, or it successor agency, to determine what specific requirements are applicable, prior to constructing or reconstructing a well on this property. No well may be constructed on this property unless applicable requirements are met.

This restriction is hereby declared to be a covenant running with the land and shall be fully binding upon all persons acquiring the above-described property whether by descent, devise, purchase or otherwise. This restriction benefits and is enforceable by the Wisconsin Department of Natural Resources, its successors or assigns. The Department, its successors or assigns, may initiate proceedings at law or in equity against any person or persons who violate or are proposing to violate this covenant, to prevent the proposed violation or to recover damages for such violation.

Any person who is or becomes owner of the property described above may request that the Wisconsin Department of Natural Resources or its successor issue a determination that one or more of the restrictions set forth in this covenant is no longer required. Upon the receipt of such a request, the Wisconsin Department of Natural Resources shall determine whether or not the restrictions contained herein can be extinguished. If the Department determines that the restrictions can be extinguished, an affidavit, attached to a copy of the Department's written determination, may be recorded to give notice that this deed restriction, or portions of this deed restriction, are no longer binding.

By signing this document, John J. Lambie, Mayor, and Susan J. Duda, Clerk/Treasurer asserts that he/she is duly authorized to sign this document on behalf of the City of Kaukauna.

IN WITNESS WHEREOF, the owner of the property has executed this Declaration of Restrictions, this _____ day of _____, 2000.

WARRANTY DEED

Vol 57 Pg 71

THIS INDENTURE, made by BADGER NORTHLAND INC., also known as BADGER NORTHLAND, INC., a Corporation duly organized and existing under and by virtue of the laws of the State of Delaware, formerly known as M-F Badger Corporation, a Delaware Corporation, located at Kaukauna, Wisconsin, Outagamie County, Grantor, of the City of Kaukauna, Outagamie County, Wisconsin, hereby conveys and warrants to the CITY OF KAUKAUNA, a Wisconsin Municipal Corporation, Grantee, of the City of Kaukauna, Outagamie County, Wisconsin, for valuable consideration of $447,000, and other good and valuable consideration, the following tracts of land located in Outagamie County, State of Wisconsin:

1. All of Lots 1 through 16, in Block eight (8), of LEDYARD PLAT, and all that portion of the vacated alley located in Block 8, LEDYARD PLAT, abutting upon Lots 5 through 12, inclusive, on Second Street and upon Lots 13 through 16, inclusive, on Third Street, said vacated alley being a parcel of land 20 feet wide and 200 feet long, all according to the recorded Assessor's Plat of the City of Kaukauna, Outagamie County, Wisconsin.

2. That part of Lot "A" Ledyard Plat of the City of Kaukauna, bounded and described as follows: Commencing at the most Westerly corner of Block 8 of aforesaid Ledyard Plat, being a point on the Northeasterly line of Third Street; thence Northwesterly along said Northeasterly line of Third Street, a distance of 723.5 feet to a point distant 25 feet Southerly, measured radially, from the center line of the Main track of the Chicago and North Western Railway Company, as said main track is now located; thence Easterly along a line parallel with said main track center line, said parallel line being a curved line concave to the South and having a radius of 810.00 feet (the long chord of which forms an angle of 24°32' as measured from Southeast to East, with the Northeasterly line of Third Street and has a length of 226.7 feet) a distance of 227.45 feet to the point of beginning of the parcel of land herein described: thence Easterly along a curved line convex to the South and having a radius of 920 feet (the chord of which forms an angle of 14°20' to the right of an extension Easterly, of the long chord of the last described curve and has a length of 289.9 feet) a distance of 291.11 feet: thence Easterly along a straight line which forms an angle of 8°10' to the left of an extension, Easterly of the long chord of the last described curve, a distance of 237 feet, more or less, to an intersection with the Southwesterly line of Second Street extended Northwesterly; thence Southeasterly along the extension of said Southwesterly line of Second Street, a distance of 6.8 feet, more or less, to the most Northerly corner of aforesaid Block 8, Ledyard Plat: thence Northeasterly along the Northeasterly extension of the Northwesterly line of said Block 8, a distance of 43 feet, more or less, to a point distant 25 feet Southwesterly, measured at right angles, from the center line of the main track of the Chicago and North Western Railway Company aforesaid: thence Northwesterly along a line parallel with said main

to the point of beginning. (The above described premises located in the unplatted part of Ledyard Plat according to the recorded Assessor's Plat of the City of Kaukauna, Outagamie County, Wisconsin, excepting and reserving unto the Chicago and Northwestern Railroad Company, a Wisconsin corporation, the right to maintain, operate, use, reconstruct and replace any and all existing conduits, sewers, water mains, gas lines, electric power lines, communication lines, wires and other utilities upon said premises.

3. A part of Lot "B" in the Plat of Ledyard, now a part of the City of Kaukauna, bounded and described as follows: Commencing at the point of intersection of the Northwesterly line of Fourth Avenue (State Trunk Highway 55) and the Northeasterly line of Second Street; thence Northwesterly along said Northeasterly line of Second Street, a distance of 215 feet to the point of beginning of the parcel of land herein described; thence Northeasterly along a line at right angles to said Northeasterly line of Second Street, a distance of 110 feet, more or less, to a point distant 32 feet Southwesterly, measured at right angles, from the center line of the main track of the Chicago and North Western Railway Company, as said main track is now located; thence Southwesterly along a straight line, a distance of 335 feet, more or less, to a point on the Northeasterly line of Second Street aforesaid, distant 35 feet Southwesterly, measured at right angles, from said main track center line; thence Southeasterly along said Northeasterly line of Second Street, a distance of 315 feet, more or less, less and excepting that property conveyed by Badger Northland Inc. to the City of Kaukauna by Warranty Deed dated September 29, 1972, for road purposes. The above described premises located in the unplatted part of Ledyard Plat according to the recorded Assessor's Plat of the City of Kaukauna, Outagamie County, Wisconsin. Less and excepting a reservation unto the prior grantor, Chicago and Northwestern Railway Company, a Wisconsin corporation, for its right to maintain, operate, use, reconstruct and replace any and all existing conduits, sewers, water mains, gas lines, electric power lines, communication lines, wires and other utilities upon the premises.

4. That part of Lot "A" Ledyard Plat of the City of Kaukauna, Outagamie County and State of Wisconsin, described as follows, to-wit: Beginning at the most Westerly corner of Block 8 of aforesaid Ledyard Plat; thence Northwesterly along the Northeasterly line of Third Street, a distance of 723.5 feet to a point distant 25 feet Southerly, measured radially, from the center line of the main track of the Chicago and North Western Railway Company as said main track is now located and established; thence Easterly along a line parallel with the center line of said main track, said line being a curved line concave to the South and having a radius of 810.00 feet (the long chord of which forms an angle of $24^{\circ}32'$, as measured from Southeast to East, with the Northeasterly line of Third Street and has a length of 226.7 feet) a distance of 227.45 feet, thence Easterly along a curved line convex to the South and having a radius of 920.00 feet (the long chord of which forms an angle of $14^{\circ}20'$ to the right of an extension Easterly, of the long chord of the last described curve and has a length of 289.9 feet) a distance of 291.11 feet; thence Easterly along a straight line which forms an angle of $8^{\circ}10'$ to the left of an extension, Easterly, of the long chord

of the last described curve, a distance of 237.0 feet, more or less, to an intersection with the Southwesterly line of Second Street extended Northwesterly; thence Southeasterly along the extension of said line of Second Street, a distance of 6.8 feet, more or less, to the most Northerly corner of aforesaid Block 8, Ledyard Plat; thence Southwesterly along the Northwesterly line of said Block 8, a distance of 220.0 feet, more or less, to the point of beginning, (said premises being located in the unlotted part of Ledyard Plat according to the recorded Assessor's Plat of said City). Subject to the rights of the City of Kaukauna under a lease to construct, maintain and use a water line, as it presently exists, in such real estate.

FEE EXEMPT # 2

Except for easements, covenants and restrictions of record, and covenants for any public roadway purposes.

Exempt from Real Estate Transfer Return and transfer tax, Exempt # 2.

IN WITNESS WHEREOF, the said grantor corporation has caused these presents to be signed by Gail E. Janssen, its corporation president and countersigned by Kenneth B. Myers, its corporation secretary, at Kaukauna, Wisconsin, and its corporate seal hereunto affixed this 26th day of July, 1974.

Subject: ground use restriction

Hi John -

Thank you for your letter addressing the required deed restriction for the Waste Oil Site. I have looked back at the file to adequately address your question on which restriction can be used.

"Fischer's draft ground water use restriction (2-11-00) is not acceptable since it only describes a small portion of the entire property which does not include the entire ground water contamination plume. In February I (Tilkens) discussed this with Karen Burkman, we decided that I would draft the deed restriction ...." - Greg Tilkens Project Manager

The above memo was in the file. Thus I consulted with our legal services and prepared the restriction that I sent to you in June. The revised restriction (sent to you in June) must be filed with the county register of deeds. Failure to file the restriction may lead to further enforcement.

I would be glad to discuss this matter with you further. I can be reached at 920-303-5435.

Subject: **Deed Restriction for Kaukauna City Waste Oil Site, Kaukauna, WI**
WDNR BRRTS #03-45-001729

Dear Ms. Laatsch:

This letter is in response to your June 27, 2002, correspondence that included a deed restriction to be signed and recorded.

The City of Kaukauna had sent Mr. Greg Tilkens, Wisconsin Department of Natural Resources, a groundwater use restriction that we intended to file. I am not sure if your June letter is in response to our February 2000, letter to Mr. Tilkens or if the original correspondence was lost.

I am enclosing copies of all the information sent along with the February 2000, letter. I request that the enclosed deed restriction be the one recorded as it has already received City Council approval and includes the restrictions requested by the DNR at that time.

Please feel free to contact me with any questions or comments you may have.

Sincerely,

John Sundelius

RE: GROUNDWATER USE RESTRICTION for Kaukauna Maintenance Garage, 222 West 3rd Street, Kaukauna, WI
FISCHER #398132.003
WDNR # 03-45-1729
PECFA #54130-2406-22

Dear Mr. Tilkens:

On behalf of the City of Kaukauna, FISCHER is submitting the enclosed draft groundwater use restriction, including attachments. Also enclosed is the most recent warranty deed on file with the Outagamie County Registrar of Deeds Office. Please note that the legal description on the deed is for the entire large parcel owned by the City. The City of Kaukauna provided the legal description representative of the area where groundwater contamination above enforcement standards still remains, and FISCHER inserted that legal description into the restriction.

Please review the enclosures and notify FISCHER if the restriction is acceptable to the Wisconsin Department of Natural Resources. Upon notification, the restriction will be finalized and filed with the Outagamie County Registrar of Deeds Office.

If you have questions or require additional information, please contact me at (920) 766-2069.

Sincerely,

FISCHER

RESOLUTION NO. 3141

RESOLUTION AUTHORIZING A WELL RESTRICTION ON CERTAIN CITY OWNED LAND IN LIEU OF FURTHER REMEDIATION ACTIVITY

WHEREAS, certain lands surrounding the fueling island adjacent to the Street Department in the Municipal Services Building have sustained some petroleum and/or lead contamination; and,

WHEREAS, remediation efforts have been completed and any remaining contamination will be naturally attenuated as approved by the Wisconsin Department of Natural Resources; and,

WHEREAS, restrictions within Wisconsin Administrative Code limit the construction of wells where certain contamination exists in the soils and the said restrictions would currently apply to the lands described below; and,

WHEREAS, it is a condition of the permission from the Wisconsin Department of Natural Resources for the use of natural attenuation that a restriction prohibiting the construction of any well upon the lands described below must be recorded with the Register of Deeds Office;

NOW, THEREFORE, BE IT RESOLVED by the Common Council of the City of Kaukauna, that the Mayor and Clerk/Treasurer are hereby authorized to execute and have recorded the attached Groundwater Use Restriction Declaration for land described as follows:

> A parcel of land located in part of Lot "A", Ledyard Plat, City of Kaukauna, State of Wisconsin, further described as follows: Commencing at the southwest corner of Lot 13, Block Eight (8), Ledyard Plat, said point also being on the northerly Right of Way line of Third Street; also the point of beginning; thence northwesterly along the northerly Right of Way line of Third Street 200 feet; thence northeasterly along a line perpendicular to said Right of Way line a distance of 78 feet; thence southeasterly along a line parallel to said Right of Way line a distance of 200 feet; thence southwesterly along the northwesterly line of Lot 13, Block 8, Ledyard Plat a distance of 78 feet to the point of beginning.

Introduced and adopted this 15th day of February, 2000.

APPROVED: John J. Lambie
John J. Lambie, Mayor

COUNTY OF Outagamie)[County where this document is signed]

WHEREAS, the City of Kaukauna is the owner of the above-described property.

WHEREAS, one or more petroleum discharges have occurred on this property. Petroleum-contaminated groundwater above ch. NR 140, Wis. Adm. Code enforcement standards existed on this property on November 29, 1999 at the location of monitoring well MW-4 [benzene was detected at 260 micrograms per liter (ug/l)]. The area of groundwater contamination with contaminant concentrations exceeding ch. NR 140, Wis. Adm. Code enforcement standards is estimated on Attachment 1. One soil sample collected from the vadose zone from three feet below ground surface from the north sidewall of the final excavation had a lead concentration of 110 milligrams per kilogram (mg/kg) on February 24, 1999. The area of soil contamination in the vadose zone on the property with a lead concentration exceeding the ch. NR 720, Wis. Adm. Code residual contaminant level is estimated on Attachment 2. Attachments 1 and 2 are made part of this restriction.

WHEREAS, it is the desire and intention of the property owner to impose on the property restrictions which will make it unnecessary to conduct further groundwater or soil remediation activities on the property at the present time.

WHEREAS, natural attenuation has been approved by the Department of Natural Resources to remediate groundwater contamination exceeding ch. NR 140, Wis. Adm. Code groundwater standards within the boundaries of this property.

WHEREAS, construction of wells where the water quality does not comply with drinking water standards in ch. NR 809, Wis. Adm. Code is restricted by chs. NR 811 and NR 812, Wis. Adm. Code. Special well construction standards or water treatment requirements, or both, or well construction prohibitions may apply.

NOW THEREFORE, the owner hereby declares that all of the property described above is held and shall be held, conveyed or encumbered, leased, rented, used, occupied and improved subject to the following limitation and restrictions:

> Anyone who proposes to construct or reconstruct a well on this property is required to contact the Department of Natural Resources' Bureau of Drinking Water and Groundwater, or it successor agency, to determine what specific requirements are applicable, prior to constructing or reconstructing a well on this property. No well may be constructed on this property unless applicable requirements are met.

This restriction is hereby declared to be a covenant running with the land and shall be fully binding upon all persons acquiring the above-described property whether by descent, devise, purchase or otherwise. This restriction benefits and is enforceable by the Wisconsin Department of Natural Resources, its successors or assigns. The Department, its successors or assigns, may initiate proceedings at law or in equity against any person or persons who violate or are proposing to violate this covenant, to prevent the proposed violation or to recover damages for such violation.

Any person who is or becomes owner of the property described above may request that the Wisconsin Department of Natural Resources or its successor issue a determination that one or more of the restrictions set forth in this covenant is no longer required. Upon the receipt of such a request, the Wisconsin Department of Natural Resources shall determine whether or not the restrictions contained herein can be extinguished. If the Department determines that the restrictions can be extinguished, an affidavit, attached to a copy of the Department's written determination, may be recorded to give notice that this deed restriction, or portions of this deed restriction, are no longer binding.

By signing this document, John J. Lambie, Mayor, and Susan J. Duda, Clerk/Treasurer asserts that he/she is duly authorized to sign this document on behalf of the City of Kaukauna.

IN WITNESS WHEREOF, the owner of the property has executed this Declaration of Restrictions, this _____ day of _____, 2000.

SUBJECT: Deed Restriction for Kaukauna City Waste Oil Site, Kaukauna, WI
WDNR BRRTS #03-45-001729

To the City of Kaukauna:

Please review the enclosed deed restriction for accuracy and completeness and if you approve of the content, you should sign it, or have the appropriate property owner sign it, and have it recorded at the Outagamie County Register of Deeds Office, and then submit a copy of the recorded document to the Department. Please be aware that if a deed restriction is recorded for the wrong property because of an inaccurate legal description you have provided, you will be responsible for correcting the problem.

The Department must also receive documentation of proper abandonment of any and all monitoring wells, extraction wells, sumps, piezometers and soil venting systems if you do not intend to perform long term monitoring at your site. Documentation of proper soil disposal (i.e. landfill disposal tickets) will also need to be submitted. Once all this information has been received, the case will be conditionally closed.

If you have any additional relevant information concerning this matter which was not formerly provided to the Department, you should submit this information to the Department for reevaluation.

If you have any questions or concerns, please contact me at 920-303-5435.

Sincerely,

Cheryl Laatsch

Declaration of Restrictions

In Re: the property described in Exhibit A hereby attached and made a part of this restriction.

Recording Area

Name and Return Address

STATE OF WISCONSIN)
) ss
COUNTY OF OUTAGAMIE)

Parcel Identification Number (PIN)

WHEREAS, the City of Kaukauna is the owner of the above-described property.

WHEREAS, one or more petroleum discharges have occurred on this property. Petroleum contaminated groundwater above ch. NR 140, Wis. Adm. Code enforcement standards existed on this property at the following location(s) on the following date(s): monitoring well 4 (MW-4) benzene is 260 micrograms per liter on November 29, 1999, and iron is 10 milligrams per liter on April 8, 1999; monitoring well 1 (MW-1) iron is 10 milligrams per liter on April 8, 1999 and soil contamination existed on the property at the following location(s) on the following date(s): Soil boring 6 (B-6) with 150 milligrams per kilogram (mg/kg) lead at 1 to 3 feet, B-9 with 370 mg/kg lead, 1500 micrograms per kilogram (ug/kg) benzene, 11190 ug/kg xylene at 1-3 feet on April 15, 1998 and B15 with 2200 mg/kg gasoline range organics (GRO) ethylbenzene, 3500 mg/kg diesel range organics (DRO), 13000 ug/kg benzene, 54000 ug/kg ethylbenzene, 3500 ug/kg toluene and 166800 ug/kg xylene at 2.5 to 4.5 feet on August 28, 1998.

Location of monitoring wells and soil borings are provided on Figure 3, attached and made part of this restriction.

WHEREAS, it is the desire and intention of the property owner to impose on the property restrictions which will make it unnecessary to conduct further groundwater or soil remediation activities on the property at the present time.

WHEREAS, natural attenuation has been approved by the Department of Natural Resources to remediate groundwater contamination exceeding ch. NR 140, Wis. Adm. Code groundwater standards within the boundaries of this property.

WHEREAS, construction of wells where the water quality does not comply with drinking water standards in ch. NR 809, Wis. Adm. Code is restricted by chs. NR 811 and NR 812, Wis. Adm. Code. Special well construction standards or water treatment requirements, or both, or well construction prohibitions may apply.

NOW THEREFORE, the owner hereby declares that all of the property described above is held and shall be held, conveyed or encumbered, leased, rented, used, occupied and improved subject to the following limitation and restrictions:

The following activities are prohibited on that portion of the property described above where a cap or cover has been placed as described in Figure 3, unless prior written approval has been obtained from the Wisconsin Department of Natural Resources or its successor or assign: (1) Excavating or grading of the land surface; (2) Filling on the capped area; (3) Plowing for agricultural cultivation; and (4) Construction or installation of a building of other structure with a foundation that would sit on or be places within a cap or cover. In addition, the cap or cover shall be maintained in compliance with a plan prepared and submitted to the Wisconsin Department of Natural Resources by a responsible party, as required by section NR 724.13 (2), Wis. Adm. Code (1999).

Anyone who proposes to construct or reconstruct a well on this property is required to contact the Department of Natural Resources' Bureau of Drinking Water and Groundwater, or it successor agency, to determine what specific requirements are applicable, prior to constructing or reconstructing a well on this property. No well may be constructed on this property unless applicable requirements are met.

This restriction is hereby declared to be a covenant running with the land and shall be fully binding upon all persons acquiring the above-described property whether by descent, devise, purchase or otherwise. This restriction benefits and is enforceable by the Wisconsin Department of Natural Resources, its successors or assigns. The Department, its successors or assigns, may initiate proceedings at law or in equity against any person or persons who violate or are proposing to violate this covenant, to prevent the proposed violation or to recover damages for such violation.

Any person who is or becomes owner of the property described above may request that the Wisconsin Department of Natural Resources or its successor issue a determination that one or more of the restrictions set forth in this covenant is no longer required. Upon the receipt of such a request, the Wisconsin Department of Natural Resources shall determine whether or not the restrictions contained herein can be extinguished. If the Department determines that the restrictions can be extinguished, an affidavit, attached to a copy of the Department's written determination, may be recorded to give notice that this deed restriction, or portions of this deed restriction, are no longer binding.

By Signing the document, _____asserts that he/she is duly authorized to sign this document on behalf of the City of Kaukauna.

GROUND WATER USE RESTRICTION

2/2/00 J.S.
ENGR. DEPT.

TELEPHONE LOG

SITE NAME: Kaukauna Waste Oil DATE: 11/19/00

DNR NO.: 03-45-001729 TIME: 9:15

PECFA CLAIM NO.:

TO/FROM: Karen Barkman NUMBER: (800) (920) (715) (414) 766-2069 (608)

COMPANY/AGENCY: Fischer

→ told her of closure & that I was E-mailing her the G.W. use Restr Form for her to fill out

→ told her to send Greg a copy (electronic) & hard copy of draft.

SCOTT MILLER

479-00

With additional info (Fischer rpt – 12-13-99) closure of the site was acceptable (Miller ltr – 1-19-00) however, the Miller letter only asks for a ground water use restriction, it should of asked for a soil deed restriction and ground water use rest (see closure committee comments on 11-8-99 closure package). In addition, Fischer's draft ground water use rest. (2-11-00) is not acceptable since it only describes a small portion of the entire property which does not include the entire ground water contamination plume. In February '00 I discussed this with Karen Burkman, we decided that I would draft the deed rest. to include the soil rest. language and she would supply me with a description of a portion of the entire property that included the plume (the area highlighted in Fischer's draft rest. plus the area of the Municipal building also shown in Fischer's draft rest.). Attached to this page is a disk that includes a deed restriction for the site. In it the appropriate property description must be inserted.

Another issue is that the closure committee states that a "soil deed restriction" must be filed for the contaminated soil that remains. The soil that remains is shallow (<4 ft) and exceeds our Pb RCL and in one sample the COMM 46 benzene direct contact number in another. I think there should be an institutional control deed rest. filed for the site which requires the maintenance of the asphalt over the contaminated soil. The attached rest. on the disk is written to be an institutional control rest. and ground water use rest. If you (whoever you is :-) think a general soil rest. is OK, then change the restriction.

RE: GROUNDWATER USE RESTRICTION for Kaukauna Maintenance Garage, 222 West 3rd Street, Kaukauna, WI
FISCHER #398132.003
WDNR # 03-45-1729
PECFA #54130-2406-22

Dear Mr. Tilkens:

On behalf of the City of Kaukauna, FISCHER is submitting the enclosed draft groundwater use restriction, including attachments. Also enclosed is the most recent warranty deed on file with the Outagamie County Registrar of Deeds Office. Please note that the legal description on the deed is for the entire large parcel owned by the City. The City of Kaukauna provided the legal description representative of the area where groundwater contamination above enforcement standards still remains, and FISCHER inserted that legal description into the restriction.

Please review the enclosures and notify FISCHER if the restriction is acceptable to the Wisconsin Department of Natural Resources. Upon notification, the restriction will be finalized and filed with the Outagamie County Registrar of Deeds Office.

If you have questions or require additional information, please contact me at (920) 766-2069.

Sincerely,

FISCHER

Karen A. Burkman

Parcel Identification Number (PIN)

STATE OF WISCONSIN)
) ss
COUNTY OF Outagamie)[County where this document is signed]

WHEREAS, the City of Kaukauna is the owner of the above-described property.

WHEREAS, one or more petroleum discharges have occurred on this property. Petroleum-contaminated groundwater above ch. NR 140, Wis. Adm. Code enforcement standards existed on this property on November 29, 1999 at the location of monitoring well MW-4 [benzene was detected at 260 micrograms per liter (ug/l)]. The area of groundwater contamination with contaminant concentrations exceeding ch. NR 140, Wis. Adm. Code enforcement standards is estimated on Attachment 1. One soil sample collected from the vadose zone from three feet below ground surface from the north sidewall of the final excavation had a lead concentration of 110 milligrams per kilogram (mg/kg) on February 24, 1999. The area of soil contamination in the vadose zone on the property with a lead concentration exceeding the ch. NR 720, Wis. Adm. Code residual contaminant level is estimated on Attachment 2. Attachments 1 and 2 are made part of this restriction.

WHEREAS, it is the desire and intention of the property owner to impose on the property restrictions which will make it unnecessary to conduct further groundwater or soil remediation activities on the property at the present time.

WHEREAS, natural attenuation has been approved by the Department of Natural Resources to remediate groundwater contamination exceeding ch. NR 140, Wis. Adm. Code groundwater standards within the boundaries of this property.

WHEREAS, construction of wells where the water quality does not comply with drinking water standards in ch. NR 809, Wis. Adm. Code is restricted by chs. NR 811 and NR 812, Wis. Adm. Code. Special well construction standards or water treatment requirements, or both, or well construction prohibitions may apply.

NOW THEREFORE, the owner hereby declares that all of the property described above is held and shall be held, conveyed or encumbered, leased, rented, used, occupied and improved subject to the following limitation and restrictions:

> Anyone who proposes to construct or reconstruct a well on this property is required to contact the Department of Natural Resources' Bureau of Drinking Water and Groundwater, or it successor agency, to determine what specific requirements are applicable, prior to constructing or reconstructing a well on this property. No well may be constructed on this property unless applicable requirements are met.

This restriction is hereby declared to be a covenant running with the land and shall be fully binding upon all persons acquiring the above-described property whether by descent, devise, purchase or otherwise. This restriction benefits and is enforceable by the Wisconsin Department of Natural Resources, its successors or assigns. The Department, its successors or assigns, may initiate proceedings at law or in equity against any person or persons who violate or are proposing to violate this covenant, to prevent the proposed violation or to recover damages for such violation.

Any person who is or becomes owner of the property described above may request that the Wisconsin Department of Natural Resources or its successor issue a determination that one or more of the restrictions set forth in this covenant is no longer required. Upon the receipt of such a request, the Wisconsin Department of Natural Resources shall determine whether or not the restrictions contained herein can be extinguished. If the Department determines that the restrictions can be extinguished, an affidavit, attached to a copy of the Department's written determination, may be recorded to give notice that this deed restriction, or portions of this deed restriction, are no longer binding.

By signing this document, John J. Lambie, Mayor, and Susan J. Duda, Clerk/Treasurer asserts that he/she is duly authorized to sign this document on behalf of the City of Kaukauna.

IN WITNESS WHEREOF, the owner of the property has executed this Declaration of Restrictions, this _____ day of _____, 2000.

SUBJECT: Closure - Kaukauna City Waste Oil Site,
WDNR BRRTS ID #:03-45-001729

Dear Mr. Sundelius:

On December 16, 1999 the Department received your Addendum to Case Closure Request. After review the Department feels that the site meets the requests of the additional word described in the letter sent on November 10,1999.

- Soil contamination at boring location B-3 (MW-1) must be further investigated for direct contact concerns.

- A minimum of one additional round of groundwater samples analyzed for PVOC and naphthalene to evaluate post remediation contaminant trend.

Please complete the attached restriction and return a draft to this office for approval with a copy of the deed/legal description, survey map if available and a site map showing the contaminated groundwater locations. Pending Department approval the restrictions can be filed with the Outagamie County Register of Deeds. Only when the Department has received documentation that the restriction has been filed with County Register of Deeds Office and the monitoring wells abandoned according to the requirements of NR 141 Wis. Adm. Code, will the Department consider the site closed.

If you have any questions, please contact Greg Tilkens at (920) 492-5868 or Scott C. Miller at (920) 492-5871.

Sincerely,

Scott C. Miller
Hydrogeologist

RE: ADDENDUM TO CASE CLOSURE REQUEST for Kaukauna Maintenance Garage, 222 West 3rd Street, Kaukauna, WI
FISCHER #398132.003
WDNR # 03-45-1729
PECFA #54130-2406-22

Dear Mr. Tilkens:

On behalf of the City of Kaukauna, FISCHER has completed the attached addendum to the closure request dated September 1, 1999.

FISCHER understands the Wisconsin Department of Natural Resources (WDNR) denied closure for two reasons. The WDNR requested another round of groundwater sampling to verify the contaminant concentrations detected after remediation. The WDNR was also concerned about a comment listed on OMNNI's soil boring log for boring B-3. On this log, it states, "solvent/paint odor" associated with the two to four foot soil sample. The WDNR questioned whether or not chlorinated solvents were present at the location of boring B-3, based on this comment. Since OMNNI did not analyze the soil sample reportedly emitting a solvent odor, the WDNR requested a sample be collected and analyzed for volatile organic compounds (VOC).

Attached is the groundwater analytical report associated with the sampling event conducted on November 29, 1999. MW-4 in the only monitoring well with contaminants above Wisconsin Administrative Code (WAC) Chapter NR 140 enforcement standards. The analyte was benzene at 260 micrograms per liter (ug/l). However, this concentration is significantly lower than the previous analytical concentration of 1,100 ug/l and continues to show a downward trend. Also attached is a summary of the groundwater analytical results to-date. Based on the these results, it is FISCHER's opinion that:

- remedial activities and natural attenuation have reduced contaminant concentrations in groundwater,
- the most recent analytical results verify the initial post-remediation results,
- and contaminant trends are decreasing.

A soil probe (GP-1) was advanced approximately one foot west of boring B-3 (well MW-1) on November 24, 1999. The probe, located on Figure 1 (attached), was advanced to four feet (ft)

below ground surface (bgs) with continuous soil sampling and field screening. Unusual odors or elevated photoionization detector (PID) readings were not detected. A soil boring log and borehole abandonment form are attached. The soil sample was collected from three ft bgs for VOC analysis. Attached is the soil analytical report. Only m,p-xylenes were detected, at a concentration of 320 milligrams per kilogram (mg/kg), which is below the WAC Chapter NR 720 generic residual contaminant level (RCL). Chlorinated solvents were not detected in the soil sample.

In conclusion, source control has been implemented to essentially eliminate the "environmental factor" and enhance remediation by natural attenuation. The site does not appear to pose additional risk. Therefore, it is FISCHER's opinion this site meets the criteria for closure with a groundwater use restriction.

If you have questions or require additional information, please contact me at (920) 766-2069.

Sincerely,

FISCHER

Karen A. Burkman

The "Q" flag is present when a parameter has been detected below the LOQ. This indicates the results are qualified due to the uncertainty of the parameter concentration between the LOD and the LOQ.

Soil VOC detects are corrected for the total solids, unless otherwise noted.

I certify that the data contained in this Final Report has been generated and reviewed in accordance with approved methods and Laboratory Standard Operating Procedure. Exceptions, if any, are discussed in the accompanying sample comments. Release of this final report is authorized by Laboratory management, as is verified by the following signature. Reported results shall not be reproduced, except in full, without the written approval of the lab. The sample results relate only to the analytes of interest tested.

J. Durocher — 12/9/99

The "Q" flag is present when a parameter has been detected below the LOQ. This indicates the results are qualified due to the uncertainty of the parameter concentration between the LOD and the LOQ.

Soil VOC detects are corrected for the total solids, unless otherwise noted.

I certify that the data contained in this Final Report has been generated and reviewed in accordance with approved methods and Laboratory Standard Operating Procedure. Exceptions, if any, are discussed in the accompanying sample comments. Release of this final report is authorized by Laboratory management, as is verified by the following signature. Reported results shall not be reproduced, except in full, without the written approval of the lab. The sample results relate only to the analytes of interest tested.

PECFA #54130-2406-22

Dear Mr. Moser:

On behalf of Mr. John Sundelius, representative of the City of Kaukauna, FISCHER is responding to your November 8, 1999 letter where you indicate the Department of Commerce (COMM) "has determined that there are two occurrences at this site."

Based on our telephone conversation, it appears you are of the opinion that groundwater at the location of well MW-1 is impacted from another source and not the waste oil system or the gasoline and diesel fuel systems. You also indicated well MW-1 is not side gradient or down gradient of the gasoline/diesel fuel underground storage tanks (USTs).

Upon review of your letter, FISCHER contacted Mr. Greg Tilkens, project manager at the Wisconsin Department of Natural Resources (WDNR). Mr. Tilkens did not receive a copy of your letter and indicated you did not contact him to discuss your determination of two contaminant plumes. Therefore, FISCHER explained the contents of your letter and telephone conversation. Based on our brief conversation, Mr. Tilkens did not appear to agree with the determination that two plumes are present. Perhaps Mr. Tilkens, COMM, the client, and FISCHER should openly discuss your concerns.

OMNNI Associates (OMNNI) conducted an initial site investigation at the subject site near the waste oil UST. OMNNI's investigation did not center on the gasoline/diesel fuel USTs. OMNNI installed well MW-1 at a location OMNNI believed to be down gradient of the waste oil tank bed. Well MW-1 was initially sampled on April 12, 1994. The following compounds were detected in the groundwater sample: benzene, 1,2-dichloroethane (1,2-DCA), ethylbenzene, methyl-tert-butyl-ether (MTBE), m,p-xylenes, cadmium, and diesel range organics (DRO).

The following comments are based on FISCHER's experience at other petroleum-contaminated sites.

- The waste oil, gasoline, and/or diesel USTs could be the source of benzene. However, the most likely source is the gasoline USTs.

- The gasoline USTs are the most likely source of the 1,2-DCA, ethylbenzene, MTBE, and m,p-xylene contamination.

- The waste oil UST is the most likely source of the cadmium contamination.

- The diesel fuel and/or waste oil USTs are the most likely source of the DRO contamination.

Based on the initial groundwater analytical results associated with well MW-1, another source of contamination, in addition to the waste oil UST, appeared to be present. FISCHER was then contracted to investigate potential contamination associated with the gasoline and/or diesel fuel USTs. Soil and groundwater contamination associated with the gasoline and diesel fuel USTs were detected.

As part of FISCHER's investigation, three additional on-site groundwater monitoring wells and one bedrock piezometer were installed and sampled. Petroleum volatile organic compounds (PVOC), other volatile organic compounds (VOC) often detected at petroleum-contaminated sites, and polynuclear aromatic hydrocarbons (PAH) often associated with waste oil and/or diesel fuel USTs were detected in groundwater samples collected from the monitoring wells, except wells MW-3 and MW-6.

It is FISCHER's opinion, based on the analytical results for groundwater samples collected from the on-site wells, that the gasoline, diesel fuel, and waste oil USTs are all a source of contamination and that one co-mingled plume exists.

You expressed the opinion that well MW-1 was not side gradient or down gradient of the gasoline/diesel fuel USTs and therefore, groundwater contamination detected in well MW-1 could not have migrated from these USTs. Since you also expressed the opinion that the waste oil UST is not the source of some of the contaminants detected in well MW-1, specifically 1,2-DCA, you concluded another source of contamination exists.

FISCHER disagrees with your assessment of groundwater flow direction. The April 21, 1998 groundwater flow map presented in FISCHER's *Site Investigation Report*, dated October 2, 1998, portrayed groundwater flow to be southeasterly. Another FISCHER hydrogeologist subsequently reviewed this assessment and determined groundwater flow on that day to be more easterly. Therefore, based on groundwater levels measured on April 21, 1998, well MW-2 is down gradient of the gasoline/diesel fuel USTs but whether or not well MW-1 is side gradient or down gradient of the gasoline/diesel fuel USTs is not conclusive.

The September 16, 1998 groundwater flow map presented in FISCHER's *Site Investigation Report* portrayed groundwater flow to be easterly and southeasterly. Another FISCHER hydrogeologist subsequently reviewed this assessment and determined groundwater flow on that day to be more northeasterly. Therefore, based on groundwater levels measured on September 16, 1998, well MW-2 is down gradient of the gasoline/diesel fuel USTs but whether or not well MW-1 is side gradient or down gradient of the gasoline/diesel fuel USTs is not conclusive.

The April 8, 1999 groundwater flow map presented in FISCHER's *Remediation Documentation Report*, dated July 21, 1999, portrayed groundwater flow to be northeasterly. Therefore, based on groundwater levels measured on that day, well MW-2 is down gradient and well MW-1 is side gradient of the gasoline/diesel fuel USTs.

The site investigation area consists of fill overlying bedrock, and in some instances overlying clay over bedrock. Groundwater flow direction in an urban area, especially in fill areas, can be variable. The Fox River is located approximately 600 feet northeast of the site investigation area. Groundwater flow direction and levels may fluctuate due to variations in seasonal precipitation, including the elevation of the nearby river, lateral drainage conditions, and soil permeability characteristics. Groundwater contour maps depict groundwater flow direction representative of one time on one day. Groundwater flow direction can change.

Borings B-1 and B-11 were advanced between the gasoline/diesel fuel USTs and the waste oil UST. One soil sample was collected for laboratory analysis from the water table interface in boring B-1. Benzene and MTBE were detected. A soil sample was collected for laboratory analysis from the vadose zone in boring B-11. DRO and toluene were detected. Boring B-3 was converted to monitoring well MW-1. A soil sample was collected for laboratory analysis from the water table interface in boring B-3. M,p-xylenes were detected. Therefore, based on these analytical results, there is no data indicating "clean" soil or groundwater between the gasoline/diesel fuel USTs and well MW-1.

Related to the issue of contaminant sources, the WDNR recently denied case closure for two reasons. The WDNR requested another round of groundwater sampling to verify the contaminant concentrations detected after remediation. The WDNR was also concerned about a comment listed on OMNNI's soil boring log for boring B-3. On this log, it states, "solvent/paint odor" associated with the two to four foot soil sample. The WDNR questioned whether or not chlorinated solvents were present at the location of boring B-3, based on this comment. Since OMNNI did not analyze the soil sample reportedly emitting a solvent odor, the WDNR requested a sample be collected.

FISCHER recently collected a soil sample at three feet (ft) below ground surface (bgs) from a location one foot west of boring B-3 (well MW-1). The soil probe extended to four ft bgs and soil samples were field screened with a photoionization detector (PID). PID readings above background and unusual odors were not detected. A soil boring log indicates the presence of fill at the location of probe GP-1. The soil sample collected from probe GP-1, at three ft bgs, was analyzed for VOC. Only m,p-xylenes were detected above the laboratory's LOD. A copy of the analytical report is attached. Therefore, based on the PID and analytical results associated with the soil sample collected from the probe, solvents are not present. This verifies a separate non-petroleum related source of contamination is not present in the area of boring B-3. In addition, non-petroleum related VOC have not been detected in any of the groundwater samples collected.

Based on the soil and groundwater analytical results and assessments of groundwater flow direction, it is FISCHER's opinion that the waste oil, gasoline, and diesel fuel USTs are all sources of contaminants detected in well MW-1. Therefore, it is FISCHER's opinion that one co-mingled plume exists and that one WDNR BRRT's number is appropriate. Since only one plume exists, only one PECFA claim number and one PECFA claim deductible applies.

If you have questions or comments, please contact FISCHER.

Sincerely,

FISCHER

Karen A. Burkman
Professional Soil Scientist

The "Q" flag is present when a parameter has been detected below the LOQ. This indicates the results are qualified due to the uncertainty of the parameter concentration between the LOD and the LOQ.

Soil VOC detects are corrected for the total solids, unless otherwise noted.

SUBJECT: Closure - Kaukauna City Waste Oil Site, WDNR BRRTS ID #: 03-45-001729

Dear Mr. Sundelius:

Your case file was recently submitted to the Bureau for Remediation and Redevelopment's Northeast Region Closeout Committee. This panel reviews environmental remediation cases for compliance with state laws, standards and guidelines to maintain consistency in the closeout of cases. After careful review, the panel has decided this case cannot be closed at this time. We believe the following additional work must be completed before the case is further reviewed for closure.

- Soil contamination at boring location B-3 (MW-1) must be further investigated for direct contact concerns.

- A minimum of one additional round of groundwater samples analyzed for PVOC and naphthalene to evaluate post remediation contaminant trend.

If you have additional relevant information concerning this matter which was not formerly provided to the Department, and which you feel would significantly impact the Department's closure decision, you may submit that information for our re-evaluation of case closure.

If you have any questions, please contact me at (920) 492-5868.

Sincerely,

Greg Tilkens, P.G.
Hydrogeologist

CASE SUMMARY AND CLOSE OUT FORM

Form4400-202
Rev. 5/98

WDNR BRRTS Case #: 03-45-001729 WDNR Site Name: ~~Kaukauna Maintenance Garage~~ Kaukauna City - Waste Oil

NOTE: Use of this form is required by the Department for any case close out application filed pursuant to ch. 292, Wis. Stats. and ch. NR 726, Wis. Adm. Code. Completion of this form is mandatory for the applications case closure. The Department will not consider or act upon your application unless you complete and submit this application form. It is not the Department's intention to use any personally identifiable information from this form for any purpose other than reviewing close out requests and determining the need for additional response action.

I certify that, to the best of my knowledge, the information presented on and attached to this form is true and accurate. This recommendation for case closure is based upon all available data as of _____(date). I have read the Case Summary and Close Out Form Instructions and all required information has been included.

X **Closure Denied, Needs More:**

- X Investigation of soils at MW-1/B-3 location to establish PVOC direct contact concerns
- X Groundwater Monitoring minimum of one additional round PVOC & Napthalene to establish post remediation trend for NA closure
- _____ Soil Remediation
- _____ Groundwater Remediation
- _____ Documentation Of Soil Landspreading Or Biopile Destiny
- X Specific Comments: Closure will require soil deed restrictions at MW-5/B-15 for BETX; MW-2/B-6 for lead and at excavation north side for lead

Will also need well use restriction ~~at~~ MW-4 (Benzene, Napthalene and Iron) Also MW-1 (Iron) ~~dependent~~ dependent upon further monitoring.

TO: Closure Committee
FROM: Tilkens

Soil is fill to approximately 8 ft, then weathered bedrock grading to competent rock (dolomite). Watertable is at approximately 5 ft bgs One soil sample was tested for lab perm. at 10^{-7} (no field tests done), all boring logs indicate soil type as "fill" except B-15 which indicates a large percentage sand. Considering that together with the fact that bedrock is very near the surface, I think this site should be considered "permeable" (note that the consultant considers the site to be low permeability based on the one lab perm test).

Release reported as part of underground waste oil tank piping upgrade. Leak from piping found through tightness testing.

5 borings installed, 1 monitoring well Pgs 7-10

High PID response at B-3 2-4 ft bgs, soils were noted to smell of solvent, not waste oil. Note soil from 4-6 ft bgs was lab analyzed rather than the contaminated surface soils from the boring.

Other tanks on site investigated (pg 11) Tanks contained diesel and gas.

11 more borings installed (pg 12)

Field screening and boring sample analysis Pgs 13-15

Borings B-6, B-9, and B-15 only locations with unsaturated soil with high PIDs above the watertable

Borings B-6, B-8, B-9, and B-15 have RCL exceedances above watertable.

Note high PID response at B-8 at depth , yet a shallow sample is lab analyzed. In fact, this shallow sample was only one analyzed for PAHs

Pg 16 - Their map of soil contamination extent

Pg 17 - X-section. Note soil sample RCL exceedances above watertable

Remediation

Three tanks identified on pg 18 were removed from the site and 1 upgraded. The consultant acknowledges that contaminated soil my remain under the upgraded tank.

Excavation as shown on pg 19

Soil went to Ridgeview LF biopile (receipts submitted)

Pg 20-21 is soil confirmation sample results.

From closure rpt. " only one sidewall sample could be collected before the waste oil excavation required backfilling in order to prevent damage to utilities". Note that the ones sample was taken from the opposite side of the tank from the adjacent boring location where high PID and solvent odor were noticed.

The consultant states that "water rapidly flowed into the excavation" and pictures show a pool of water during excavation – further evidence that these soils are not low permeability.

So, soil contamination remains at MW-1 where a PID response of 1,000 and soils that smelled of solvent were present from 2-4 ft bgs (pg 8); at MW-5 (B-15) where all BTEX exceed the RCL 2.5 – 4.5 ft bgs, in fact benzene exceeds the COMM 46 # (pg 15); at MW-2 (B-6) where Pb exceeds RCL 1-3 ft bgs (pg 14); and excavation confirmation point N-Side where Pb exceeds RCL at 3 ft bgs (pg 21)

Pj 22 is a post remediation x-section.

Pj 23 is post remediation site map.

Groundwater

Pgs 24-16 are groundwater flow maps. The April '99 flow direction is disturbing, but is based on measurements taken 2 months after excavation backfilling (possibly before groundwater is in equilibrium) so may not be representative. The NA data from wells MW-1 and 6 indicates they are down gradient wells as shown on the other 2 maps. I think the April '98 and September '98 maps are representative of groundwater flow.

Groundwater data is pgs 27-32

Regarding equilibrium, note there is only one groundwater sample taken after the excavation (2 months after). I don't think that sample result should be considered representative either.

SW-1 and SW-2 are sumps installed during excavation backfilling (on pg 23).

NA parameters between the upgradient well (MW-3) and contaminated well MW-4 indicate NA is happening although there is very little DO available from upgradient. Since MW-1, 4, and 6 all have elevated methane, and MW-1 and 4 have elevated Fe, it looks like methanogenesis and Fe reduction may be the dominant NA mechanisms at the site.

Note that Fe in MW-4 and MW-1 is way over the Fe ES (33 times the ES).

The concentration trends in the contaminated wells is favorable, but is based on only 3 rounds of data (MW-2 and 4) one of which was collected 2 months after excavation that may not be representative of static conditions.

COMM 46

Environmental Factors –

Expanding plume - From data provided plume looks receding, but there are few rounds and the last data point may not represent static conditions.

Potable well PAL exceedance - No wells reported to be in area.

Contamination within 1 meter of bedrock – Yes. Groundwater is at 4-5 ft bgs, bedrock is at approximately 10, so any groundwater contamination is likely within 1 meter of bedrock. There is a well in bedrock/weathered bedrock (MW-5) which in the most recent round tested clean, I have static conditions concern again, but before excavation the only exceedance in the well was 5.5 benzene.

Free product - None reported.

Surface Water or Wetland discharge - None reported.

Risk Criteria

Off-site Contamination - None reported. Contamination seems contained within area bounded by site buildings.

Direct Contact - Yes. At MW-1 where a PID response of 100 and soils that smelled of solvent were present from 2-4 ft bgs (pg 8); MW-5 (B-15) where all BTEX exceed the RCL 2.5 – 4.5 ft bgs, in fact benzene exceeds the COMM 46 # (pg 15); MW-2 (B-6) where Pb exceeds RCL 1-3 ft bgs (pg 14); and excavation confirmation point N-Side where Pb exceeds RCL at 3 ft bgs (pg 21)

Contamination > ESx300 - N/A since I don't think the site meets low permeability criteria.

5 Foot separation to developable groundwater/decreasing concentration with depth - The deepest boring in the contaminated area contains decreasing soil contamination with depth.

Impacts to receptors - None reported.

ES exceedance within 1000 feet of Public well - Not reported.

ES exceedance within 100 feet of Private well - No well reported present on site

Recommendation

Deny closure. Request:

Investigation of soil contamination in area of MW-1 (B-3) (Note that a groundwater sample from MW-1 was analyzed for VOCs and no compounds except for BTEX + 1,2 DCA were detected)

Collect additional groundwater samples to document contamination status after excavation when site is in equilibrium

Excavate soils which pose a direct contact threat. See "Direct Contact", above, minus the soils at MW-1(B-3)

Define extent of Fe down gradient, monitor groundwater to show NA of Fe

If committee chooses closure:

Deed restriction requiring institutional control (cap) for soils that pose direct contact threat for soils identified under "Direct Contact", above, minus the soils at MW-1 (B-3)

General deed restriction for soils at MW-1(B-3)

Groundwater use restriction for benzene and Fe at MW-4, and Fe at MW-1

CASE SUMMARY
KAUKAUNA MAINTENANCE GARAGE

The Kaukauna Maintenance Garage is located at 222 West 3rd Street, Kaukauna, Wisconsin (WI). The subject site is owned and operated by the City of Kaukauna and is currently used as a municipal maintenance garage. Five underground storage tanks (USTs) are registered with the Department of Commerce (COMM) for the site: two 10,000-gallon diesel fuel, one 10,000-gallon leaded gasoline, one 10,000-gallon unleaded gasoline, and one 550-gallon waste oil UST. The 10,000-gallon unleaded gasoline UST was upgraded and left in place and one new 10,000-gallon diesel fuel UST was installed. The remaining three USTs were removed from the site during the remedial excavation activities.

OMNNI Associates (OMNNI) previously conducted a site investigation during which five soil borings were advanced at the site and one boring was converted into groundwater monitoring well MW-1. Based on a review of OMNNI's *Site Investigation Report*, dated June 1994, it was FISCHER's opinion that the extent of contamination from the other site USTs was not adequately defined.

The City of Kaukauna contracted FISCHER on February 18, 1998 to perform a site investigation to further define the extent of contamination. As part of the site investigation activities, 11 soil borings were advanced at the site; four were converted into groundwater monitoring wells and one was converted into a bedrock piezometer.

The vertical and horizontal extent of soil and groundwater contamination on-site was defined for the purposes of the site investigation. Contamination was detected within one meter of bedrock, and, therefore, an "environmental factor", as defined in COMM 47, was present.

FISCHER evaluated remedial alternatives and submitted a *Remedial Action Plan* (RAP), dated October 5, 1998. FISCHER proposed to address the "environmental factor" and contaminants by excavating a portion of the impacted soil and conducting additional groundwater monitoring.

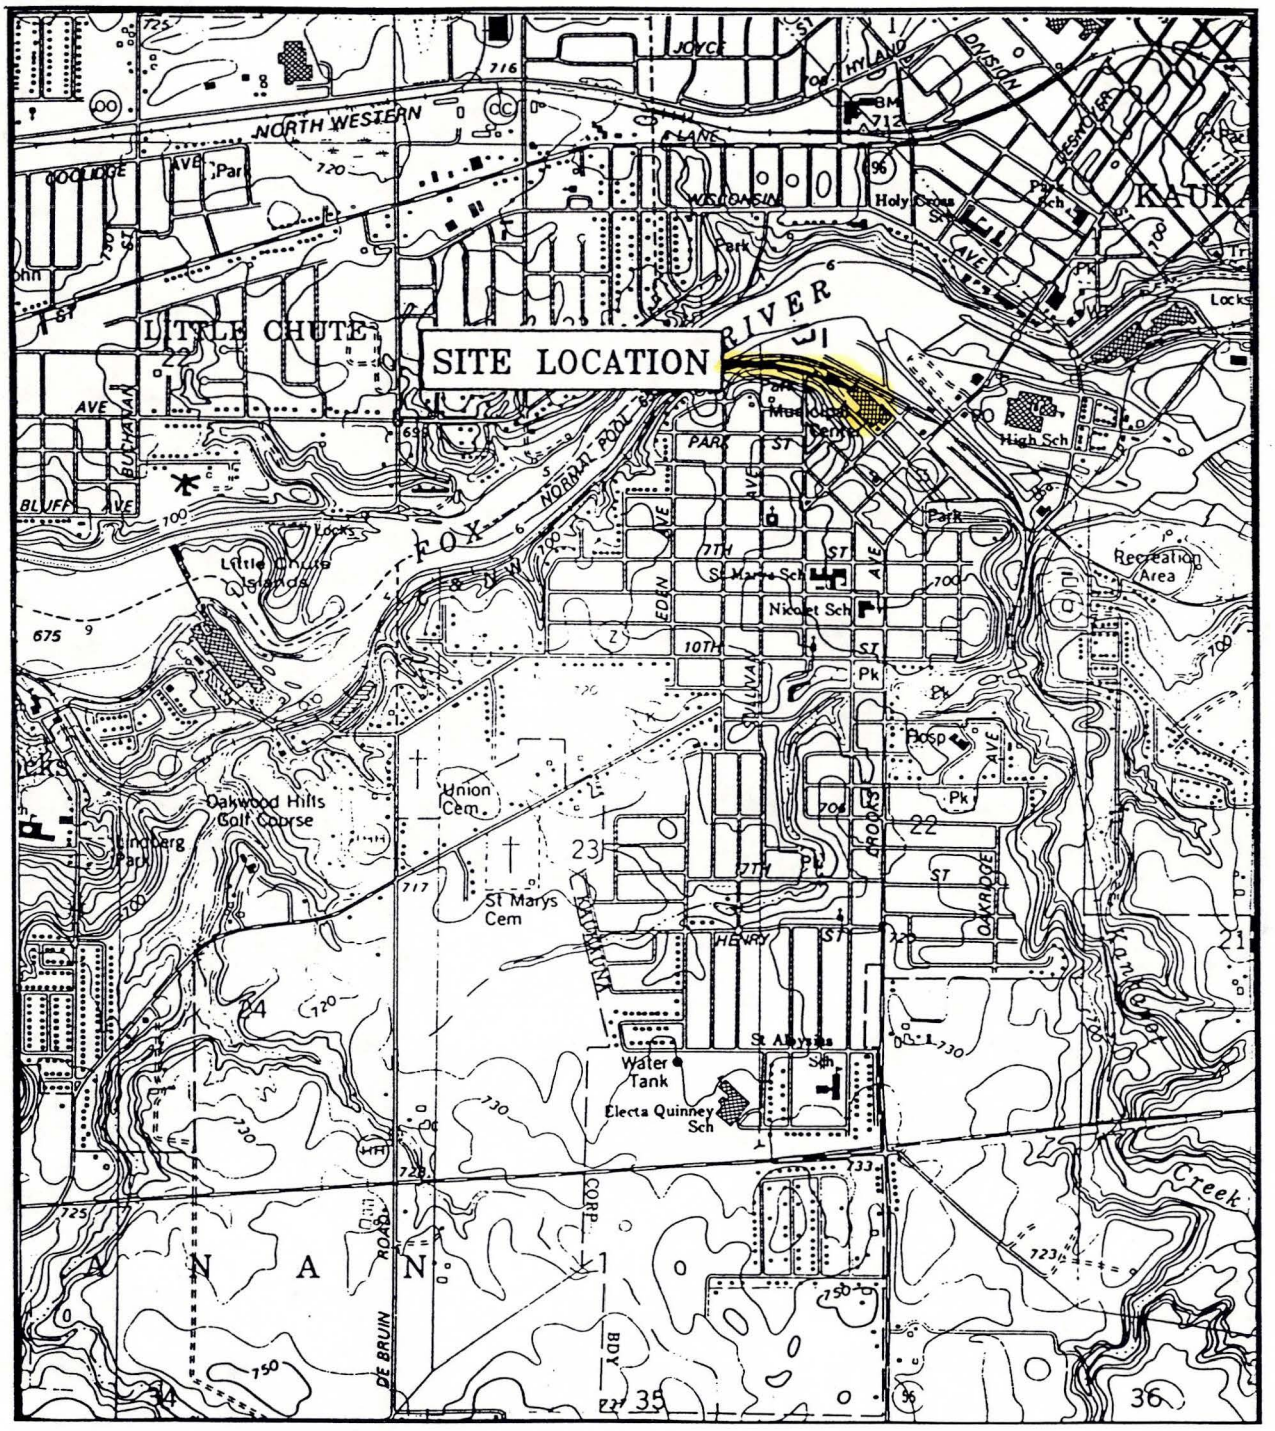
From February 23 through 25, 1999, 1,389.75 tons of petroleum-impacted soil were excavated from two areas on the site and transported to the Ridgeview BioSite for bioremediation treatment. In order to excavate soil to bedrock to eliminate the "environmental factor", 203,985 gallons of groundwater were pumped from the largest excavation and transported to the Heart of the Valley municipal treatment plant located in Kaukauna. Two sump wells were installed during remedial excavation backfill operations.

Closure soil samples were collected from the base and sidewalls of the final excavations to verify any remaining contaminant concentrations. Analytical results indicate the majority of soil with contaminant concentrations exceeding Wisconsin Administrative Code (WAC) Chapter NR 720 generic residual contaminant levels (RCLs) has been excavated. One post-excavation groundwater monitoring event has been performed and the analytical results indicate soil remediation and natural attenuation have reduced contaminant concentrations in the groundwater.

JUSTIFICATION FOR CLOSURE
KAUKAUNA MAINTENANCE GARAGE

In accordance with rule COMM 47, FISCHER evaluated five "environmental factors". Prior to source removal (excavation and off-site bioremediation treatment of 1,389.75 tons of impacted soil), one "environmental factor" appeared to be present. Impacted soil was located within one meter of bedrock. The "environmental factor" was eliminated during remedial activities, with the exception of impacted soil possibly located beneath the UST that was upgraded.

Closure soil samples were collected during remedial excavation activities. Only one of the 16 closure samples had a contaminant concentration (lead) exceeding generic RCLs and was collected from the vadose zone. It is FISCHER's opinion that a deed restriction is not warranted for the following reasons.



- only one sample collected from the vadose zone exceeded the generic RCL;
- only the RCL for lead was exceeded in the closure sample;
- the excavation could not extend laterally beyond the closure sample location where an RCL exceedance was detected due to the presence of the building;
- the site is currently paved;
- the site will remain paved in the foreseeable future; and
- exposure by direct contact is not anticipated.

Laboratory analytical results of groundwater samples from monitoring wells MW-1, MW-2, MW-3, MW-5 and MW-6, and sump wells SW-1 and SW-2 during April 1999 did not have contaminant concentrations exceeding NR 140 enforcement standards. Prior to soil remediation, benzene was detected in monitoring well MW-2 and piezometer MW-5 at concentrations above the NR 140 enforcement standard. Therefore, remedial activities and natural attenuation appear to have reduced contaminant concentrations in groundwater at the locations of well MW-2 and bedrock piezometer MW-5.

Only benzene was detected at a concentration above the NR 140 enforcement standard in the groundwater sample collected from well MW-4 during April 1999. The benzene concentrations detected in groundwater samples collected from well MW-4 have decreased by approximately 50% subsequent to the remedial excavation activities. Prior to soil remediation, naphthalene, trimethylbenzenes, and xylenes had also been detected in groundwater samples collected from well MW-4 at levels above the NR 140 enforcement standards. Therefore, remedial activities and natural attenuation appear to have reduced contaminant concentrations in groundwater at the location of well MW-4.

FISCHER reviewed COMM 46 as it relates to the remediation status of this site. Based on the most recent groundwater analytical results, only benzene in well MW-4 is present at a concentration exceeding the NR 140 enforcement standard. The benzene concentration, 1,100 micrograms per liter (ug/l), is less than 300 times the NR 140 enforcement standard of 5 ug/l. Groundwater contamination has not been detected off-site.

Source control has been implemented to essentially eliminate the "environmental factor" and enhance remediation by natural attenuation. The site does not appear to pose additional risk. Therefore, it is FISCHER's opinion that this site meets the criteria for closure with a groundwater use restriction.

SUBJECT: Acknowledgment of Receipt/Request for Closure Review, Kaukauna Maintenance Garage; 222 3rd Street; Kaukauna; Outagamie County, Wisconsin
WDNR BRRTS ID #: 03-45-001729

Dear Mr. Sundelius:

The Department received your request for closeout review on September 17, 1999. Due to staffing levels and the backlog of non-emergency cases, requests for closure are logged and reviewed in the order they are received. However, we hope to be able to review your request within two months. After Department review of the case, a letter will notify you either that closure is approved or that additional work is required.

If you have any questions, please contact me at (920) 492-5868.

Sincerely,

Greg Tilkens
Hydrogeologist

Dear Mr. Tilkens:

Please accept the enclosed check as payment for review of the closure request previously submitted to you for the above-referenced site.

If you have questions or require additional information, please contact me at (920) 766-2069.

Sincereiy,

FISCHER

Karen A. Burkman
Professional Soil Scientist

CASE SUMMARY
KAUKAUNA MAINTENANCE GARAGE

The Kaukauna Maintenance Garage is located at 222 West 3rd Street, Kaukauna, Wisconsin (WI). The subject site is owned and operated by the City of Kaukauna and is currently used as a municipal maintenance garage. Five underground storage tanks (USTs) are registered with the Department of Commerce (COMM) for the site: two 10,000-gallon diesel fuel, one 10,000-gallon leaded gasoline, one 10,000-gallon unleaded gasoline, and one 550-gallon waste oil UST. The 10,000-gallon unleaded gasoline UST was upgraded and left in place and one new 10,000-gallon diesel fuel UST was installed. The remaining three USTs were removed from the site during the remedial excavation activities.

OMNNI Associates (OMNNI) previously conducted a site investigation during which five soil borings were advanced at the site and one boring was converted into groundwater monitoring well MW-1. Based on a review of OMNNI's *Site Investigation Report*, dated June 1994, it was FISCHER's opinion that the extent of contamination from the other site USTs was not adequately defined.

The City of Kaukauna contracted FISCHER on February 18, 1998 to perform a site investigation to further define the extent of contamination. As part of the site investigation activities, 11 soil borings were advanced at the site; four were converted into groundwater monitoring wells and one was converted into a bedrock piezometer.

The vertical and horizontal extent of soil and groundwater contamination on-site was defined for the purposes of the site investigation. Contamination was detected within one meter of bedrock, and, therefore, an "environmental factor", as defined in COMM 47, was present.

FISCHER evaluated remedial alternatives and submitted a *Remedial Action Plan* (RAP), dated October 5, 1998. FISCHER proposed to address the "environmental factor" and contaminants by excavating a portion of the impacted soil and conducting additional groundwater monitoring.

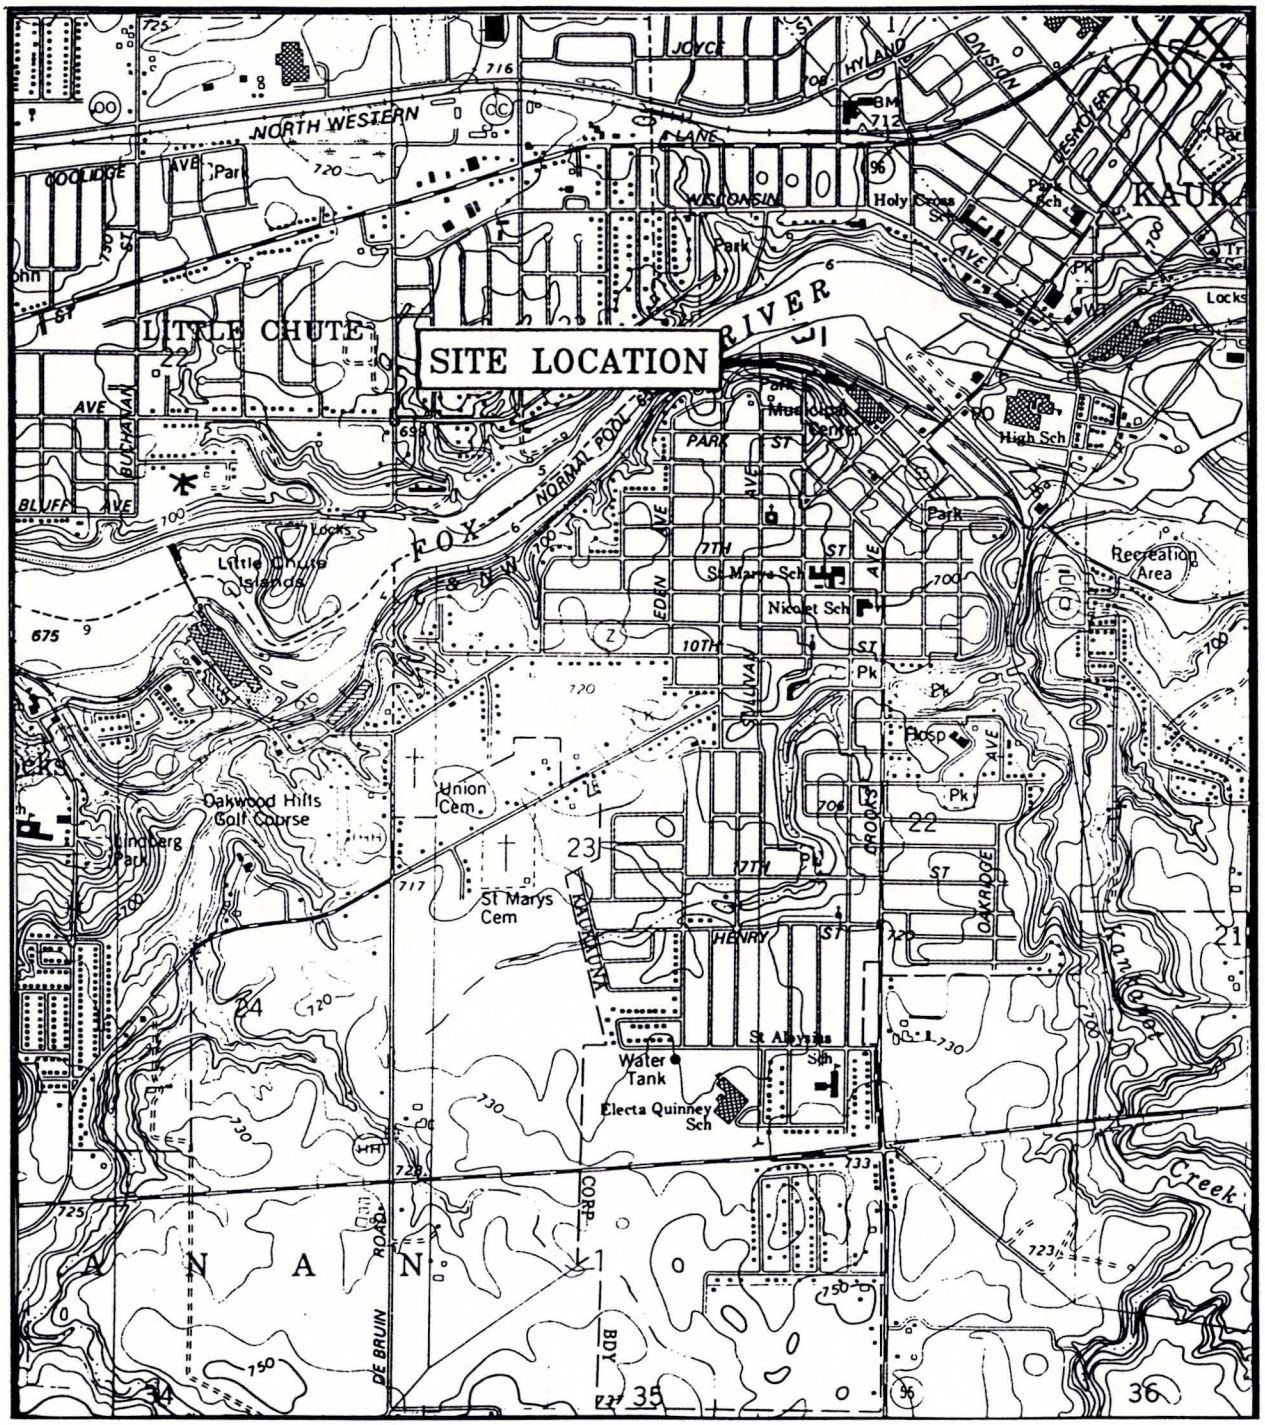
From February 23 through 25, 1999, 1,389.75 tons of petroleum-impacted soil were excavated from two areas on the site and transported to the Ridgeview BioSite for bioremediation treatment. In order to excavate soil to bedrock to eliminate the "environmental factor", 203,985 gallons of groundwater were pumped from the largest excavation and transported to the Heart of the Valley municipal treatment plant located in Kaukauna. Two sump wells were installed during remedial excavation backfill operations.

Closure soil samples were collected from the base and sidewalls of the final excavations to verify any remaining contaminant concentrations. Analytical results indicate the majority of soil with contaminant concentrations exceeding Wisconsin Administrative Code (WAC) Chapter NR 720 generic residual contaminant levels (RCLs) has been excavated. One post-excavation groundwater monitoring event has been performed and the analytical results indicate soil remediation and natural attenuation have reduced contaminant concentrations in the groundwater.

JUSTIFICATION FOR CLOSURE
KAUKAUNA MAINTENANCE GARAGE

In accordance with rule COMM 47, FISCHER evaluated five "environmental factors". Prior to source removal (excavation and off-site bioremediation treatment of 1,389.75 tons of impacted soil), one "environmental factor" appeared to be present. Impacted soil was located within one meter of bedrock. The "environmental factor" was eliminated during remedial activities, with the exception of impacted soil possibly located beneath the UST that was upgraded.

Closure soil samples were collected during remedial excavation activities. Only one of the 16 closure samples had a contaminant concentration (lead) exceeding generic RCLs and was collected from the vadose zone. It is FISCHER's opinion that a deed restriction is not warranted for the following reasons.



- only one sample collected from the vadose zone exceeded the generic RCL;
- only the RCL for lead was exceeded in the closure sample;
- the excavation could not extend laterally beyond the closure sample location where an RCL exceedance was detected due to the presence of the building;
- the site is currently paved;
- the site will remain paved in the foreseeable future; and
- exposure by direct contact is not anticipated.

Laboratory analytical results of groundwater samples from monitoring wells MW-1, MW-2, MW-3, MW-5 and MW-6, and sump wells SW-1 and SW-2 during April 1999 did not have contaminant concentrations exceeding NR 140 enforcement standards. Prior to soil remediation, benzene was detected in monitoring well MW-2 and piezometer MW-5 at concentrations above the NR 140 enforcement standard. Therefore, remedial activities and natural attenuation appear to have reduced contaminant concentrations in groundwater at the locations of well MW-2 and bedrock piezometer MW-5.

Only benzene was detected at a concentration above the NR 140 enforcement standard in the groundwater sample collected from well MW-4 during April 1999. The benzene concentrations detected in groundwater samples collected from well MW-4 have decreased by approximately 50% subsequent to the remedial excavation activities. Prior to soil remediation, naphthalene, trimethylbenzenes, and xylenes had also been detected in groundwater samples collected from well MW-4 at levels above the NR 140 enforcement standards. Therefore, remedial activities and natural attenuation appear to have reduced contaminant concentrations in groundwater at the location of well MW-4.

FISCHER reviewed COMM 46 as it relates to the remediation status of this site. Based on the most recent groundwater analytical results, only benzene in well MW-4 is present at a concentration exceeding the NR 140 enforcement standard. The benzene concentration, 1,100 micrograms per liter (ug/l), is less than 300 times the NR 140 enforcement standard of 5 ug/l. Groundwater contamination has not been detected off-site.

Source control has been implemented to essentially eliminate the "environmental factor" and enhance remediation by natural attenuation. The site does not appear to pose additional risk. Therefore, it is FISCHER's opinion that this site meets the criteria for closure with a groundwater use restriction.

EXPLANATION

SOILS CLASSIFICATION		MONITORING WELL
ASPHALT	See bore logs	Bentonite Seal
FILL	See bore logs	Water table measured on 9/16/98
CL	Inorganic clays of low to medium plasticity, gravelly clays, sandy clays, silty clays, lean clays.	Well Screen
GM	Silty gravels, gravel–sand–silt mixtures.	
BEDROCK	See bore logs	
WEATHERED BEDROCK	See bore logs	
	Not observed

Kaukauna Cty –

Dear Mr. Tilkens:

On behalf of the City of Kaukauna (the responsible party), FISCHER is submitting the attached report summarizing the remedial excavation and sampling activities performed at the Kaukauna Maintenance Garage during February 1999. This report also discusses the results of one groundwater monitoring event performed subsequent to the remedial excavation activities.

If you have any questions regarding this project please contact me at (920) 766-2069.

Sincerely,

FISCHER

Karen A. Burkman
Professional Soil Scientist

EXECUTIVE SUMMARY

The Kaukauna Maintenance Garage is located at 222 West 3rd Street in the City of Kaukauna, Outagamie County, Wisconsin (WI). Acronyms used throughout this report are referenced in Appendix A. The site presently operates as a maintenance garage and is owned by the City of Kaukauna. Five underground storage tanks (USTs) are registered with the Department of Commerce (COMM) for the site: two 10,000-gallon diesel fuel, one 10,000-gallon leaded gasoline, one 10,000-gallon unleaded gasoline, and one 550-gallon waste oil UST. The 10,000-gallon unleaded gasoline UST was upgraded and left in place and one new 10,000-gallon diesel fuel UST was installed. The remaining three USTs were removed from the site during the remedial excavation activities.

OMNNI Associates (OMNNI) previously conducted a site investigation with regards to the waste oil UST. Based on review of OMNNI's *Site Investigation Report*, the extent of contamination from the waste oil UST was not yet defined at that time. Reportedly, OMNNI collected a groundwater sample from a sump located near the remaining USTs and the analytical results indicated contamination.

The City of contracted FISCHER to perform a site investigation. Site investigation data was presented in FISCHER's *Site Investigation Report*, dated October 2, 1998. As part of FISCHER's site investigation activities, 11 soil borings were advanced at the site; four were completed as groundwater monitoring wells and one was completed as a bedrock piezometer. Contamination was detected within one meter of bedrock, and, therefore, an "environmental factor", as defined in COMM 47, appeared to be present.

FISCHER evaluated remedial alternatives and submitted a *Remedial Action Plan,* dated October 5, 1998. FISCHER proposed to address the "environmental factor" and contaminants by excavating a portion of the impacted soil and conducting additional groundwater monitoring.

From February 23 through 25, 1999, 1,389.75 tons of petroleum-impacted soil were excavated from two areas on the site and transported to the Ridgeview BioSite for bioremediation treatment. In order to excavate soil to bedrock to eliminate the "environmental factor", 203,985 gallons of groundwater were pumped from the largest excavation and transported to the Heart of the Valley municipal treatment plant located in Kaukauna. Two sump wells were installed during remedial excavation backfill operations.

Closure soil samples were collected from the base and sidewalls of the final excavations to verify any remaining contaminant concentrations. Analytical results indicate the majority of soil with contaminant concentrations exceeding Wisconsin Administrative Code (WAC) Chapter NR 720 generic residual contaminant levels has been excavated. One post-excavation groundwater monitoring event has been performed and the analytical results indicate soil remediation and natural attenuation have reduced contaminant concentrations in the groundwater.

SUBMITTAL CERTIFICATION

"I, Karen A. Burkman, hereby certify that I am a scientist as that term is defined in s. NR 712.03(3), Wis. Adm. Code, and that, to the best of my knowledge, all of the information contained in this document is correct and the document was prepared in compliance with all applicable requirements in chs. NR 700 to 726, Wis. Adm. Code."

1.0 INTRODUCTION

1.1 PURPOSE

The purpose of this report is to summarize the remedial action performed on-site during February 1999 and provide the Wisconsin Department of Natural Resources (WDNR) with an update of the groundwater monitoring results subsequent to remedial excavation activities. Acronyms used throughout this report are referenced in Appendix A.

1.2 PROJECT BACKGROUND

The Kaukauna Maintenance Garage is located at 222 West 3rd Street, Kaukauna, Wisconsin (WI). A site location map is presented in Figure 1. The subject site is owned and operated by the City of Kaukauna and is currently used as a municipal maintenance garage. Five underground storage tanks (USTs) are registered with the Department of Commerce (COMM) for the site: two 10,000-gallon diesel fuel, one 10,000-gallon leaded gasoline, one 10,000-gallon unleaded gasoline, and one 550-gallon waste oil UST. The 10,000-gallon unleaded gasoline UST was upgraded and left in place and one new 10,000-gallon diesel fuel UST was installed. The remaining three USTs were removed from the site during the remedial excavation activities. UST locations are identified on Figure 2.

OMNNI Associates (OMNNI) previously conducted a site investigation during which five soil borings were advanced at the site and one boring was converted into groundwater monitoring well MW-1. Based on a review of OMNNI's *Site Investigation Report*, dated June 1994, it was FISCHER's opinion that the extent of contamination from the other site USTs was not adequately defined.

The City of Kaukauna contracted FISCHER on February 18, 1998 to perform a site investigation to further define the extent of contamination. As part of the site investigation activities, 11 soil borings were advanced at the site; four were converted into groundwater monitoring wells and one was converted into a bedrock piezometer.

The vertical and horizontal extent of soil and groundwater contamination on-site was defined for the purposes of the site investigation. Contamination was detected within one meter of bedrock, and, therefore, an "environmental factor", as defined in COMM 47, was present.

FISCHER evaluated remedial alternatives and submitted a R*emedial Action Plan* (RAP), dated October 5, 1998. FISCHER proposed to address the "environmental factor" and contaminants by excavating a portion of the impacted soil and conducting additional groundwater monitoring.

1.3 SITE INFORMATION AND CONTACTS

Site Name and Location:	Kaukauna Maintenance Garage 222 West 3rd Street Kaukauna, WI 54130 Northeast ¼ of Government Lot 22, Township 22 North, Range 18 East of Outagamie County
Current Site Owner:	City of Kaukauna Department of Public Works P.O. Box 890 Kaukauna, WI 54130 Contact: Mr. John Sundelius – Street Superintendent Phone: (920) 766-6337
Consultant:	FISCHER P.O. Box 127 Kaukauna, WI 54130 Phone: (920) 766-2069
Project Manager:	Ms. Karen Burkman FISCHER P.O. Box 127 Kaukauna, WI 54130 Phone: (920) 766-2069
Project Hydrogeologist:	Mr. Robert H. Klauk, P.G. FISCHER P.O. Box 127 Kaukauna, WI 54130 Phone: (920) 766-2069
Site Operations:	The property is used as a municipal maintenance garage.

2.0 REMEDIAL ACTION

2.1 REMEDIAL EXCAVATION

Remedial excavation activities were performed by Gene Frederickson Trucking (GFT), Kaukauna, WI, under the direction of FISCHER personnel. During soil excavation activities, Fox Valley Petroleum Service (Little Chute, WI), Schroeder Environmental Cleaning Services, Inc. (DePere, WI) and GFT removed and cleaned three USTs, upgraded one 10,000 gallon UST, and installed a new 10,000 gallon UST in the remedial excavation, all under contracts separate from the contract for soil remediation. Holes were not observed in any of the removed USTs, however, some pitting was evident. The USTs were transported to GFT for scrap. Photographs of the soil excavation and tank removal activities are included in Appendix B.

Impacted soil was excavated from the site from February 23 through 25, 1999. Excavation activities were performed at two separate site locations, as proposed in the remedial action plan. The limits of the two excavation areas are identified on Figure 3. The eastern portion of the larger excavation extended to approximately six feet (ft) below ground surface (bgs). The northwest portion of the larger excavation extended only to approximately four ft bgs because the UST in this area was upgraded and left in place. The remainder of the larger excavation extended to bedrock, to approximately 12 to 13 ft bgs. The smaller excavation, near the former waste oil UST, extended to the apparent bedrock surface (approximately 8.5 ft bgs).

Groundwater rapidly flowed into the larger excavation and seeped into the waste oil UST excavation. In order to eliminate the "environmental factor" at this site, impacted soil within three ft of bedrock needed to be excavated. In order to achieve that goal, 203,985 gallons of contaminated groundwater was pumped from the larger excavation during soil removal. The impacted groundwater pumped from the excavation was transported by GFT to the Heart of the Valley municipal treatment plant located in Kaukauna, WI.

While excavating, FISCHER collected soil samples for olfactory and visual evaluation of hydrocarbon contamination, as well as field screening. FISCHER also used the site investigation results to direct excavation activities.

GFT excavated 1,389.75 tons of impacted soil and transported it to the Waste Management Ridgeview BioSite located in Whitelaw, WI for bioremediation treatment. A copy of Waste Management's invoice, documenting the quantity of soil received by the BioSite, is presented in Appendix C.

Groundwater monitoring well MW-2 was not destroyed during excavation activities; however, the soil immediately surrounding this well was removed and replaced with ¾-inch washed stone during excavation backfill operations. Two sump wells, SW-1 and SW-2, were installed in the larger excavation during backfill operations. Their locations are identified in Figure 4. The two sump wells were constructed of 4-inch diameter Schedule 40 polyvinyl chloride (PVC) riser material with 10-feet of Schedule 40 PVC, 0.02 (20 slot), factory cut, flush threaded screen. The sump wells were installed during excavation backfill activities by placing ¾-inch washed stone a minimum of two feet from the well screen and a minimum of two feet above the top of the screen.

The sump wells were finished with bentonite surface seal and a steel flushmount protective casing set in a concrete surface pad.

After the remedial excavation activities were complete, the 10,000 gallon UST was upgraded and the new UST was installed. Upon completion of the UST upgrade/installation, the largest excavation was backfilled. Due to the presence of subsurface water and sewer utility lines within the waste oil UST excavation, backfill operations were performed as quickly as possible to prevent damage to the utility lines. The excavations were backfilled with compacted ¾-inch washed stone. Three-quarter-inch washed stone was placed around the screen of monitoring well MW-2. Pump islands were subsequently installed over the larger excavation area for the upgraded and new USTs and the site was paved.

2.2 CONFIRMATION AND CLOSURE SAMPLING

One soil sample was randomly collected from each of two dump trucks as they left the site to document levels of soil contamination in the excavated soil. These samples are identified as "Confirmation #1, and #2". Both soil samples exhibited strong petroleum odors and PID field screening indicated the presence of volatile organic vapors.

Twelve soil closure samples were collected from the sidewalls of the larger excavation, and one from a sidewall of the waste oil UST excavation. Due to the accumulation of groundwater in the bottom of both excavations, only three soil samples were collected from the floor of the largest excavation. Only one sidewall sample could be collected before the waste oil UST excavation required backfilling in order to prevent damage to the adjacent subsurface utilities. The sidewall and floor closure samples were collected for laboratory analysis in order to identify remaining soil impacts. Sample locations are identified on Figure 3.

Closure samples were weighed in the field with a digital scale. Approximately 25 grams of soil were placed into clean laboratory prepared jars. Each GRO/PVOC soil sample was preserved utilizing premeasured laboratory grade methanol. A portion of the closure samples were also analyzed for lead. All samples were then transported, on ice, to EnChem, Inc. (WDNR #405132750) using standard chain-of-custody procedures. Closure soil samples were analyzed for gasoline range organics (GRO), diesel range organics (DRO), and petroleum volatile organic compounds (PVOC).

2.2.1 Soil Analytical Results

Laboratory analytical results, for the soil samples discussed in Section 2.2, are included in Appendix D and summarized in Table 1. Of the 16 closure samples analyzed, three had contaminant concentrations exceeding generic residual contaminant levels (RCLs). In the soil sample collected from the north sidewall in the eastern portion of the larger excavation, from a depth of approximately three ft bgs, lead was detected at a concentration of 110 milligrams per kilogram (mg/kg). This closure sample was collected from the apparent vadose zone. In the soil sample collected from the base of the larger excavation, above the upgraded UST, from a depth of approximately four ft bgs, benzene was detected at a concentration of 200 micrograms per kilogram (ug/kg). This closure

sample was collected from below the static groundwater table, as measured in nearby monitoring wells. In the soil sample collected from the west side of the larger excavation, from a depth of approximately five ft bgs, the following contaminants were detected at levels above the RCLs: DRO (1,800 mg/kg), GRO (700 mg/kg), benzene (1,700 ug/kg), ethylbenzene (11,000 ug/kg), and xylenes (39,800 ug/kg). This closure sample was also collected from below the static groundwater table, as measured in nearby monitoring wells.

3.0 POST REMEDIAL EXCAVATION GROUNDWATER MONITORING

3.1 GROUNDWATER FLOW DIRECTION

Depth to groundwater has been periodically measured in site monitoring and sump wells, and ranges from approximately 3.5 to 4.5 ft bgs. Groundwater level data recorded to date is presented in Table 2.

Groundwater elevation data has been used to estimate the groundwater flow direction. The preferential groundwater flow direction at the site has generally been toward the east/southeast since the inception of the monitoring program. The effect of the February 1999 remedial excavation on the site groundwater flow characteristics is illustrated on Figure 5.

3.2 GROUNDWATER SAMPLING

Post-excavation groundwater samples were collected from monitoring/sump wells MW-1, MW-2, MW-3, MW-4, MW-6, and SW-1 on April 8, 1999. Monitoring well MW-5 was temporarily paved over and sump well SW-2 was inaccessible on April 8, 1999. However, wells MW-5 and SW-2 were sampled on April 15, 1999.

Groundwater samples collected in April 1999 were submitted to a Wisconsin certified laboratory for PVOC analysis. A portion of the groundwater samples were also subsequently analyzed for 1,2-dichloroethane (DCA) and naphthalene. Groundwater samples were also collected for laboratory analysis of methane, nitrate/nitrite, and sulfate, in order to evaluate natural attenuation. Each well was purged prior to sample collection.

3.2.1 Groundwater Analytical Results

The laboratory analytical reports for the groundwater samples collected in April 1999 are included in Appendix E. A summary of groundwater analytical results, to date, is presented in Tables 3 and 4.

Groundwater samples collected in April 1999 from monitoring wells MW-1, MW-2, MW-3, MW-5 (bedrock well) and MW-6, and sump wells SW-1 and SW-2 did not have contaminant concentrations exceeding Wisconsin Administrative Code (WAC) Chapter NR 140 enforcement standards. Benzene was detected above the WAC Chapter NR 140 enforcement standard, at a concentration of 1,100 micrograms per liter (ug/l) in the groundwater sample collected from well MW-4 during April 1999.

3.3 GROUNDWATER FIELD MONITORING

Groundwater in the site wells/sump was monitored for temperature, dissolved oxygen (DO), oxygen-reduction potential (ORP), and ferrous iron during the April 1999 sampling events. Due to instrument malfunction, pH and conductivity were not recorded. The field monitoring was performed to evaluate natural attenuation.

3.3.1 Groundwater Field Monitoring Results

Field monitoring results, to date, are included in Table 4. Results of the April 1999 monitoring are as follows. Nitrate/nitrite results ranged from 0.061 to 0.57 mg/l. However, 0.036 mg/l nitrate/nitrite was also detected in the laboratory quality control blank. Sulfate results ranged from 64 to 170 mg/l and methane results ranged from <0.9 to 530 ug/l. DO results ranged from 0.12 to 0.31 parts per million, ORP results ranged from –75 to 20 millivolts, and ferrous iron results ranged from 0.5 to 10 mg/l.

4.0 CONCLUSIONS

4.1 REMEDIAL ACTION

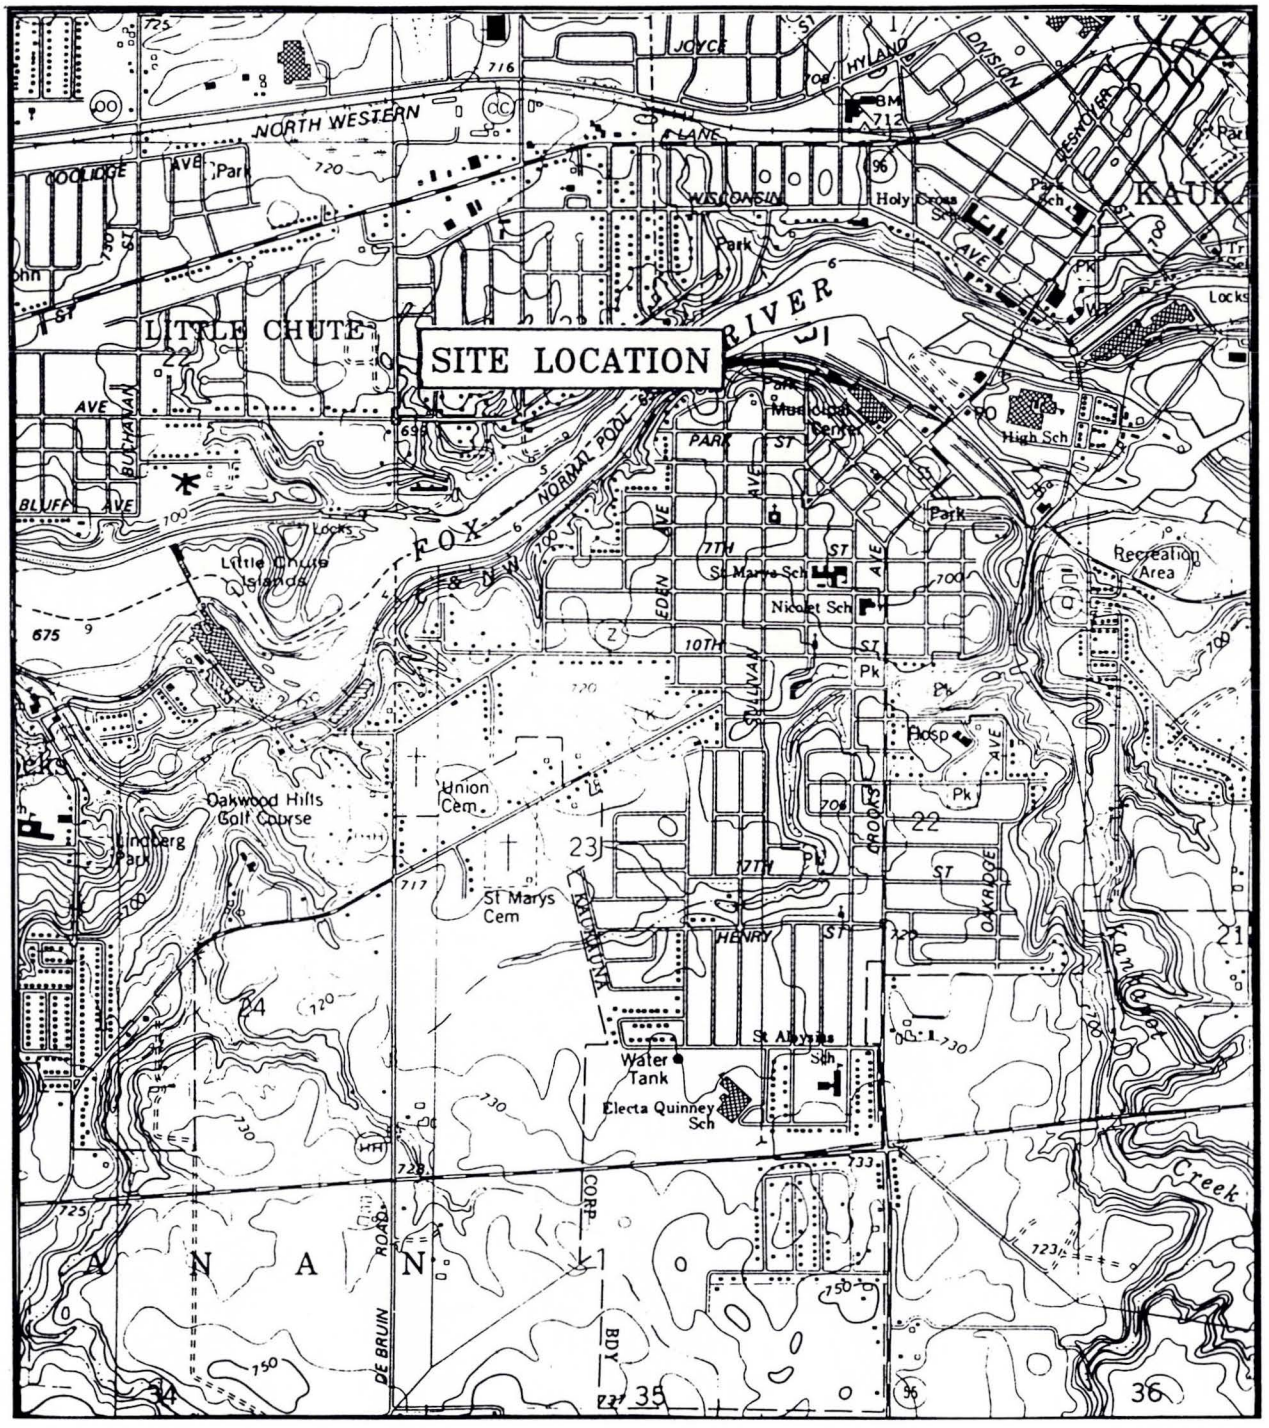
In February 1999, 1,389.75 tons of petroleum-impacted soil was excavated from two locations on the site and transported to the Ridgeview BioSite for bioremediation treatment. Both excavations extended to bedrock; therefore, the "environmental factor" appears to have been eliminated at this site, with one exception. Impacted soil may be present beneath the UST that was upgraded and left in-place.

Closure soil samples were collected during remedial excavation activities. Only one of the 16 closure samples had a contaminant concentration (lead) exceeding generic RCLs and was collected from the vadose zone. Since only one sample collected from the vadose zone exceeded the generic RCL and only for lead, the site is currently paved, and the site will remain paved in the foreseeable future, it is FISCHER's opinion that a deed restriction is not warranted.

4.2 GROUNDWATER MONITORING

Laboratory analytical results of groundwater samples from monitoring wells MW-1, MW-2, MW-3, MW-5 and MW-6, and sump wells SW-1 and SW-2 during April 1999 did not have contaminant concentrations exceeding NR 140 enforcement standards. Prior to soil remediation, benzene was detected in wells MW-2 and MW-5 at concentrations above the NR 140 enforcement standard. Therefore, remedial activities and natural attenuation appear to have reduced contaminant concentrations in groundwater at the locations of wells MW-2 and MW-5. Since bedrock well MW-5 does not appear to be impacted, additional bedrock wells are not proposed.

Benzene was detected at a concentration above the NR 140 enforcement standard in the groundwater sample collected from well MW-4 during April 1999. The benzene concentrations detected in groundwater samples collected from well MW-4 have decreased by approximately 50% subsequent to the remedial excavation activities. Prior to soil remediation, naphthalene, trimethylbenzenes, and xylenes had also been detected in groundwater samples collected from well MW-4 at levels above the NR 140 enforcement standards. Therefore, remedial activities and natural attenuation appear to have reduced contaminant concentrations in groundwater at the location of well MW-4.



4.2.1 Natural Attenuation of Groundwater

Metabolic byproduct concentrations (methane and ferrous iron) are higher within the contaminant plume compared to outside the contaminant plume. This indicates remediation by natural attenuation is occurring. The DO, nitrate/nitrite, and sulfate concentrations detected during the April 1999 sampling event could not be used to show conclusive natural attenuation trends in the site groundwater.

5.0 RECOMMENDATIONS

Since the "environmental factor" has been eliminated, with the exception of impacted soil possibly located beneath the UST that was upgraded, and groundwater contaminant concentrations have been reduced since remedial excavation operations, FISCHER recommends case closure. FISCHER will submit a separate case closure request (with a groundwater use restriction) to the WDNR.

Notes: All depths measured from Top of Casing (TOC). * = bedrock well
GW = groundwater ft = feet
Elevations in feet in reference to benchmark with an assumed elevation of 100 feet.

TABLE 3
SUMMARY OF GROUNDWATER ANALYTICAL RESULTS - MW-1
KAUKAUNA MAINTENANCE GARAGE - FISCHER #398132.003

Parameter	Sampling Date						ES	PAL
	4/12/94	1/23/95	9/26/95	4/21/98	6/5/98	4/8/99		
Cadmium	0.1	NA	NA	NA	NA	NA	5	0.5
DETECTED VOLATILE ORGANIC COMPOUNDS (VOC)								
Benzene	1.2	<0.6	<0.6	<0.27	<0.27	<0.27	5	0.5
1,2-Dichloroethane	4.9	4.7	**7.8**	NA	4.0	3.3	5	0.5
Ethylbenzene	3.6	<1.0	<1.0	<0.32	<0.32	<0.32	700	140
Methyl-Tert-Butyl-Ether	17	5.2	9.6	6.4	6.7	2.8	60	12
Xylenes, Total	23	<1.0	<1.0	<0.43	<0.43	<0.67	620	124

All concentrations in ug/l - micrograms per liter

ES - Enforcement Standard (exceedances shaded)

PAL - Preventive Action Limit

NA - not analyzed for parameter

Note: April 12, 1994, Jan 23, 1995, Sept 26, 1995, sampling events by OMNNI Associates

TABLE 3 (Continued)
SUMMARY OF GROUNDWATER ANALYTICAL RESULTS - MW-2
KAUKAUNA MAINTENANCE GARAGE - FISCHER #398132.003

Parameter	Sampling Date			ES	PAL
	4/21/98	6/5/98	4/8/99		
Lead	<1.6	NA	NA	15	1.5
DETECTED VOLATILE ORGANIC COMPOUNDS (VOC)					
Benzene	**150**	**170**	<0.26	5	0.5
Ethylbenzene	11	38	<0.24	700	140
Isopropylbenzene	1.4	NA	NA	NE	NE
Methyl-Tert-Butyl-Ether	19	17	11	60	12
n-Propylbenzene	1.2	NA	NA	NE	NE
Toluene	5.5	1.9	0.33Q	343	68.6
Trimethylbenzenes	3.7	15.32	<1.40	480	96
Xylenes, Total	9.38	26.37	<1.34	620	124

All concentrations in ug/l - micrograms per liter
ES - Enforcement Standard (exceedances shaded)
PAL - Preventive Action Limit
NA - not analyzed for parameter
NE - not established
LOQ - Limits of Quantitation
LOD - Limits of Detection
Trimethylbenzenes - Sum of 1,2,4 and 1,3,5 Trimethylbenzenes
Q = The "Q" flag is present when a parameter has been detected below the LOQ. This indicates the results are qualified due to the uncertainty of the parameter concentration between the LOD and the LOQ.

TABLE 3 (Continued)
SUMMARY OF GROUNDWATER ANALYTICAL RESULTS - MW-3
KAUKAUNA MAINTENANCE GARAGE - FISCHER #398132.003

Parameter	Sampling Date			ES	PAL
	4/21/98	6/5/98	4/8/99		
Lead	<1.6	NA	NA	15	1.5
VOLATILE ORGANIC COMPOUNDS (VOC)					
None detected	<LOD	<LOD	<LOD	Varies	Varies

All concentrations in ug/l - micrograms per liter

The "Q" flag is present when a parameter has been detected below the LOQ. This indicates the results are qualified due to the uncertainty of the parameter concentration between the LOD and the LOQ.

Soil VOC detects are corrected for the total solids, unless otherwise noted.

I certify that the data contained in this Final Report has been generated and reviewed in accordance with approved methods and Laboratory Standard Operating Procedure. Exceptions, if any, are discussed in the accompanying sample narrative. Release of this final report is authorized by Laboratory management, as is verified by the following signature.

The "Q" flag is present when a parameter has been detected below the LOQ. This indicates the results are qualified due to the uncertainty of the parameter concentration between the LOD and the LOQ.

Soil VOC detects are corrected for the total solids, unless otherwise noted.

I certify that the data contained in this Final Report has been generated and reviewed in accordance with approved methods and Laboratory Standard Operating Procedure. Exceptions, if any, are discussed in the accompanying sample narrative. Release of this final report is authorized by Laboratory management, as is verified by the following signature.

The "Q" flag is present when a parameter has been detected below the LOQ. This indicates the results are qualified due to the uncertainty of the parameter concentration between the LOD and the LOQ.

Soil VOC detects are corrected for the total solids, unless otherwise noted.

I certify that the data contained in this Final Report has been generated and reviewed in accordance with approved methods and Laboratory Standard Operating Procedure. Exceptions, if any, are discussed in the accompanying sample narrative. Release of this final report is authorized by Laboratory management, as is verified by the following signature.

The "Q" flag is present when a parameter has been detected below the LOQ. This indicates the results are qualified due to the uncertainty of the parameter concentration between the LOD and the LOQ.

Soil VOC detects are corrected for the total solids, unless otherwise noted.

I certify that the data contained in this Final Report has been generated and reviewed in accordance with approved methods and Laboratory Standard Operating Procedure. Exceptions, if any, are discussed in the accompanying sample narrative. Release of this final report is authorized by Laboratory management, as is verified by the following signature.

The "Q" flag is present when a parameter has been detected below the LOQ. This indicates the results are qualified due to the uncertainty of the parameter concentration between the LOD and the LOQ.

Soil VOC detects are corrected for the total solids, unless otherwise noted.

I certify that the data contained in this Final Report has been generated and reviewed in accordance with approved methods and Laboratory Standard Operating Procedure. Exceptions, if any, are discussed in the accompanying sample narrative. Release of this final report is authorized by Laboratory management, as is verified by the following signature.

COMM 47 REMEDIAL ALTERNATIVE RESPONSE

CLAIMANT:
City of Kaukauna Dept. of Public Works
Attn: John Sundelius
PO Box 890
Kaukauna WI 54130

CLAIM # 54130-2406-22
BRRT # 03-45-001729
SITE:
Kaukauna Maintenance Garage
222 West 3rd Street
Kaukauna WI

RECOMMENDED ALTERNATIVE: **SUBMITTAL DATE:** October 2, 1998
Excavate, Biosite approximately 1020 cubic yards and groundwater monitor

__XXX__	**Approved with cost caps**
$ 140,558.00	**Cap on total cost to closed remedial action status-**
_____	**Site will be bundled with other remediation(s)**
_____	**Site will be directed to the public bid process**

COMMENTS: The department approves the remedial approach however some costs for the groundwater monitoring program appear high. Have your consultant review the time and personnel needed to complete these tasks.

Important Claim Note: This document serves as the Department's written approval to submit your first claim for eligible site investigation and remedial action planning costs, per COMM 47.355(2)(b). Please include a copy of this document in your site investigation claim package.

- **COMM 47.33(2)(b) The cost detail for the selected remediation alternative shall establish the total estimated cost for the remediation up to the point of receiving approval as a closed remedial action.**

- **COMM 47.337(5) CLAIMANT OPTIONS. (a) After receiving an approval of a remedial action plan from the department, a claimant may elect to either implement the alternative or to select another alternative. If the claimant elects to implement a higher cost remedial strategy, the claimant must notify the department in writing of the intent to use a higher cost alternative. The notification must include the statement that the claimant agrees that the department approved alternative establishes the maximum reimbursable amount for consulting and commodity services under the fund and that additional costs for the occurrence, excluding interest, will not be submitted to the fund.**

- **COMM 47.01(3) INTENT OF PECFA. (a) The PECFA fund does not relieve a responsible party from liability. The individual or organization responsible for a contaminated property shall carry out the remediation of that property. PECFA's role is to provide monetary awards to responsible parties who have completed and paid for PECFA approved remediation activities and services. The availability or unavailability of PECFA funding shall not be the determining factor as to whether a remediation shall be completed.**

- **The approval does not guarantee the reimbursement of costs. Final determination regarding the eligibility of costs will be determined at the time of claim review. The department's approval is based on the limited information submitted in the remedial alternative cost approval document and does not imply that the department concurs that the recommended remedial alternative will achieve the remedial results anticipated by the consultant or required by law.**

FISCHER Project #398132.002
WDNR LUST ID # 03-45-1729
PECFA # 54130-2406-22

Dear Mr. McKnight:

Fischer Environmental, Inc. (FISCHER) previously submitted the "Site Investigation Report", dated October 2, 1998 for the Kaukauna Maintenance Garage. The attached forms were inadvertently excluded from that report. Please included these forms with the previously submitted report.

If you have any questions, feel free to contact Ms. Karen Burkman at (920) 766-2069.

Respectfully Submitted,

FISCHER ENVIRONMENTAL, INC.

Kaukauna, WI 54130

SUBJECT: Acknowledgment of Receipt / Notice to Proceed
Kaukauna Waste Oil Collection Site
WDNR BRRTS Unique ID # 03-45-1729

Dear Mr. Sundelius:

We have received the above-referenced submittal from Fischer Environmental, Inc.. Staffing and workload levels do not allow us to provide you with review and oversight at this time and thus this letter is not an approval of your work plans and reports. This letter serves as your "Notice to Proceed" with investigation and remediation of the site. Your submittals will be filed until the Department is able to review them, or until site remediation is completed. The entire case file will remain as part of the Department's public records.

All site work must comply with all applicable statutes, program guidance, standards and Administrative Rules. The major goals of any environmental cleanup action are to define the extent of contamination, choose appropriate remedial options and remediate soils/groundwater to state standards. It is very important that your consultant understands and meets the minimum standards established by the Department; however, you, as the responsible party, are ultimately responsible for the investigation and remediation that is required at your site, according to Wisconsin Statutes s. 292.01-292.81 Stats. Failure to follow guidance may result in timely and/or costly delays when the project is reviewed for closure or reimbursement from PECFA.

Effective this date, on a quarterly basis, you or your consultant should provide the Department with a status report, providing an update on site activities, including monitoring results, evaluations and future work, and your proposed schedule. If any emergency actions are necessary, you must notify the WDNR manager immediately. As workload and staff levels are adjusted, the status of this case may be changed and we may be able to review your consultant's work for completeness and acceptability. You will be informed, in writing, if the site management is changed.

Please send only one copy of all submittals and remember to identify all submittals with the WDNR BRR CASE ID number. All correspondence and reports should be sent to the Department at the following address:

Wisconsin Department of Natural Resources
ATTN: Remediation and Redevelopment
905 Bayshore Drive
P.O. Box 2565
Oshkosh, WI 54903

The Department will review your case when the full extent of contamination has been determined and appropriate cleanup has occurred.

If you have any questions about this letter please contact me at (920) 424-7890.

Sincerely,

Kevin D. McKnight

Dear Mr. Tsoris:

On behalf of the City of Kaukauna, the party responsible for the release at the above referenced property, Fischer Environmental, Inc. (FISCHER) is pleased to submit this Remedial Action Plan for the above referenced site. Contamination has been detected within one meter of bedrock, therefore, an "environmental factor" exists, based on COMM 47.

If you have any questions regarding this report, feel free to contact Ms. Karen Burkman at (920) 766-2069.

Respectfully Submitted,

FISCHER ENVIRONMENTAL, INC.

EXECUTIVE SUMMARY

The Kaukauna Maintenance Garage is located at 222 West 3rd Street in the City of Kaukauna, Outagamie County, Wisconsin (WI). (Acronyms used throughout this report are referenced in Appendix A.) The site presently operates as a maintenance garage and is owned by the City of Kaukauna. Four registered underground storage tanks (USTs) are located on-site: one 10,000 gallon diesel fuel, one 10,000 gallon leaded gasoline, one 10,000 gallon unleaded gasoline and one 550 gallon waste oil UST. The USTs are in use, with the exception of the UST formerly containing leaded gasoline.

OMNNI Associates (OMNNI) has been conducting a Site Investigation with regards to the waste oil UST since contamination was discovered in December of 1993. OMNNI drilled five soil borings at the site and one boring was converted into a ground-water monitoring well. Based on review of OMNNI's Site Investigation report, dated June 1994, the extent of contamination from the waste oil UST was not yet defined at that time. Reportedly, OMNNI collected a ground-water sample from a sump located near the remaining USTs and the analytical results indicated contamination from the other USTs.

Since the City of Kaukauna is in the process of upgrading or removing the UST systems, and since OMNNI detected contamination in the diesel fuel and gasoline UST area, the City contracted Fischer Environmental, Inc. (FISCHER) to perform a Site Investigation. Associated investigation data was presented in FISCHER's Site Investigation Report, dated October 2, 1998. As part of the Site Investigation activities, 11 soil borings were advanced at the site; four were converted into ground-water monitoring wells and one was converted into a bedrock piezometer.

Of the soil samples exhibiting contaminant concentrations exceeding Wisconsin Department of Natural Resources' (WDNR's) generic Residual Contaminant Levels (RCLs), only samples collected from borings B-6, 1-3 feet (ft), B-8, 1-3 ft and B-9, 1-3 ft, appear to have been collected from above the subsequent water table, as measured in the ground-water monitoring wells. Petroleum compounds detected in soil samples collected beneath or at the static water table are generally considered to be dissolved in ground water. The soil zone where ground water fluctuates can be identified as the smear zone. At this site, the vadose zone appears to be the most impacted, relative to the smear zone. The extent of soil contamination, in the vadose and smear zones, appears to have been defined and consists of approximately 1300 cubic yards, assuming an average thickness of seven feet.

Depth to ground water on the site, based on water levels in the monitoring wells, is approximately 3.5 to 4.5 ft below the ground surface (bgs). The ground-water flow is interpreted to be in a southeasterly direction.

The most recent analytical results indicated WDNR's Enforcement Standards (ES) were exceeded in ground-water monitoring wells MW-2 and MW-4 and in piezometer MW-5. The horizontal extent of ground-water contamination, based on ES exceedances, appears to have been defined. The detection of 1,2-Dichloroethane, which is generally associated with gasoline, in well MW-1 appears to indicate one ground-water contaminant plume.

Piezometer MW-5 was installed in the most impacted portion of the ground-water contaminant plume. Since Benzene was the only compound detected in piezometer MW-5 above the ES, and since it was detected at a concentration only slightly exceeding the ES, the vertical extent of ground-water contamination was considered defined for the purposes of the Site Investigation.

A subsurface utility trench appears to be present from the 10,000 gallon USTs to the building. Soil borings were drilled on each side of this utility trench. Since contamination was detected, there is a possibility the trench is a preferential migration pathway. Subsurface utility trenches appear to be present near the waste oil UST. However, based on analytical results for samples collected from nearby borings, these trenches do not appear to be preferential migration pathways.

"Environmentally sensitive areas", such as wetlands and surface waters, do not appear to be located adjacent to, or immediately down gradient of, the site. A potable well is not reportedly located on the subject site and was not evident during several site inspections. It is FISCHER's opinion that contamination has been detected within one meter of bedrock. Bedrock appeared to be present on-site as shallow as 8.5 ft bgs. Therefore, an "environmental factor" appears to be present and active remedial treatment can be justified, based on review of Department of Commerce (COMM) 47.

This Remedial Action Plan (RAP) includes an evaluation of remedial alternatives for this site.

FISCHER proposes to address the "environmental factor" and contaminants by excavating approximately 1020 cubic yards of soil and conducting additional ground-water monitoring. Assuming additional data supports Remediation by Natural Attenuation (RNA) as a final remedy after soil excavation is implemented, it is FISCHER's opinion that "flexible" closure or closure can be requested within eight sampling events. Therefore, the total remedial costs to achieve a closed remedial action are estimated to be $140,558. If RNA as the final remedy after source control does not appear to be feasible, based on the additional data, another remedial alternative may need to be implemented. Additional funds, if required, would be requested at that time.

SUBMITTAL CERTIFICATION

1.0 INTRODUCTION

1.1 BACKGROUND

The Kaukauna Maintenance Garage site is owned and operated by the City of Kaukauna and currently operates as a municipal maintenance garage. Four registered USTs are located on-site: one 10,000 gallon diesel fuel, one 10,000 gallon leaded gasoline, one 10,000 gallon unleaded gasoline and one 550 gallon waste oil UST. The USTs are in use, with the exception of the UST formerly containing leaded gasoline.

OMNNI has been conducting a Site Investigation with regards to the waste oil UST since contamination was discovered in December of 1993. OMNNI drilled five soil borings at the site and one boring was converted into a ground-water monitoring well (MW-1). Based on review of OMNNI's Site Investigation report, dated June 1994, the extent of contamination from the waste oil UST was not yet defined at that time. Reportedly, OMNNI collected a ground-water sample from a sump located near the remaining USTs and the analytical result indicated contamination from the other USTs.

Since the City of Kaukauna is in the process of upgrading or removing the UST systems, and since OMNNI detected contamination in the diesel fuel and gasoline UST area, the City contracted FISCHER on February 18, 1998 to perform a Site Investigation. As part of the Site Investigation activities, 11 soil borings were advanced at the site; four were converted into ground-water monitoring wells and one was converted into a bedrock piezometer.

Of the soil samples exhibiting contaminant concentrations exceeding WDNR's generic RCLs, only samples collected from borings B-6, 1-3 ft, B-8, 1-3 ft and B-9, 1-3 ft, appear to have been collected from above the subsequent water table, as measured in the ground-water monitoring wells. Petroleum compounds detected in soil samples collected beneath or at the static water table are generally considered to be dissolved in ground water. The soil zone where ground water fluctuates can be identified as the smear zone. At this site, the vadose zone appears to be the most impacted, relative to the smear zone. The extent of soil contamination, in the vadose and smear zones, appears to have been defined and consists of approximately 1300 cubic yards, assuming an average thickness of seven ft.

Depth to ground water on the site, based on water levels in the monitoring wells, is approximately 3.4 to 4.5 ft bgs. The ground-water flow is interpreted to be in a southeasterly direction.

The most recent analytical results indicated WDNR's Enforcement Standards (ES) were exceeded in ground-water monitoring wells MW-2 and MW-4 and in piezometer MW-5. The horizontal extent of ground-water contamination, based on ES exceedances, appears to have been defined. The detection of 1,2-Dichloroethane in well MW-1 appears to indicate one ground-water contaminant plume.

Piezometer MW-5 was installed in the most impacted portion of the ground-water contaminant plume. Since Benzene was the only compound detected in piezometer MW-5 above the ES, and since it was detected at a concentration only slightly exceeding the ES, the vertical extent of ground-water contamination was considered defined for the purposes of the Site Investigation.

"Environmentally sensitive areas", such as wetlands and surface waters, do not appear to be located adjacent to, or immediately down gradient of, the site. A potable well is not reportedly located on the subject site and was not evident during several site inspections. FISCHER is not aware of potable wells located down gradient of, or adjacent to, the subject site. Therefore, there do not appear to be any known potential receptors, with the possible exception of the Fox River, located approximately 600 feet northeast of the Kaukauna Maintenance Garage.

In a previous report, OMNNI indicated bedrock was encountered at the site at ten ft bgs. During FISCHER's Site Investigation, auger refusal, probably bedrock, was encountered at 8.5 to nine ft bgs. Soil contamination has been detected in samples collected from seven ft bgs and ground-water contamination has been detected in monitoring wells screened just above what appears to be bedrock. One of the COMM 47 "environmental factors" is the presence of contamination within one meter (three feet) of bedrock. It is FISCHER's opinion that contamination has been detected within one meter of bedrock. Therefore, an "environmental factor" appears to be present and active remedial treatment can be justified, based on review of COMM 47.

Site characteristics such as soil conditions and hydrogeology, and the nature and extent of the contamination, were described in more detail in FISCHER's Site Investigation Report.

As a result of the Site Investigation, FISCHER has prepared this Remedial Action Plan. The remediation goal for this site is to stabilize and reduce the size of the contaminated ground-water plume within a reasonable period and also to address the "environmental factor".

2.0 CONTAMINANT MASS CALCULATIONS

Based on the results of the Site Investigation, FISCHER estimated the volume and location of the mass of contaminants. FISCHER calculated there are approximately seven pounds (lbs) of total Benzene, Toluene, Ethylbenzene, Xylenes (BTEX) in the vadose zone (soil above the water table); two lbs total BTEX in the smear zone (estimated to be two ft thick); and two lbs in the ground water (contaminated zone estimated to be 5 ft thick).

3.0 EVALUATION OF REMEDIAL ALTERNATIVES

3.1 GENERAL INFORMATION

Various technological alternatives are available for the remediation of petroleum-affected soil and ground water. These alternatives are classified as either in situ (in place) or ex situ treatment. RNA may also be considered a viable alternative. Technologies are selected based on the extent of contamination, nature of contaminants, subsurface soil classifications, estimated effectiveness of the selected technology and overall cost of remediation.

In accordance with rule COMM 47, FISCHER has evaluated the following environmental factors.

1) "Documented expansion of plume margin."
2) "Verified contaminant concentrations in a private or public potable well that exceed the PAL established under Chapter, Stats. 160."
3) "Contamination within bedrock or within 1 meter of bedrock."
4) "Petroleum product that is not in the dissolved phase (floating product) is present with a thickness of 0.01 ft or more, and verified by more than one sampling event."
5) "Documented contamination discharges to a surface water or wetland."

As indicated previously, it is FISCHER's opinion that contamination has been detected within one meter of bedrock. Therefore, an "environmental factor" appears to be present and active remedial treatment can be justified, based on review of COMM 47.

3.2 REMEDIATION BY NATURAL ATTENUATION

Natural Attenuation is defined in NR 700, Wisconsin Administrative Code as "the reduction in the concentration and mass of a substance and its breakdown products in groundwater, due to naturally occurring physical, chemical, and biological processes without human intervention or enhancement. These processes include, but are not limited to, dispersion, diffusion, sorption and retardation, and degradation processes such as biodegradation, abiotic degradation and radioactive decay."

In order for case closure to be granted by the WDNR utilizing RNA as the remedial alternative, the following criteria should be met.

- Adequate source control measures have been taken.
- The ground-water contaminant plume is either stable or receding. Ground-water contamination exceeding PALs will not migrate beyond boundaries for which Ground-Water Use Restrictions are recorded.
- Natural Attenuation will bring the ground water into compliance within a reasonable period of time.
- If an Enforcement Standard(s) is exceeded, a Ground-Water Use Restriction shall be filed with the county registrar of deeds office.
- There is no existing or anticipated threat to public health, safety or welfare or the environment.

3.2.1 Source Control

The four existing USTs and associated piping and dispensers will either be upgraded to current standards or removed and possibly replaced. Impacted soil exceeding WDNR's generic RCLs is present on-site within the vadose and smear zones. Based on calculations, the total mass of BTEX appears to be greater within the vadose zone compared to the mass within the smear zone and ground water. Removal of the majority of the impacted soil and smear zone (Figure 1) would provide source control and enhance RNA. Not all of the soil exceeding RCLs will be removed from the site due to inaccessibility. The excavation will not extend to the building walls or near any USTs that will remain in place. Although pumping and disposal of contaminated ground water during excavation is anticipated, the excavation will not extend to depths that will create an excessive amount of ground water pumping and disposal, in order to control costs.

3.2.2 Plume Stability

Based on review of analytical results, the ground-water contaminant plume appears to be relatively stable. Source control would enhance the plume's stability.

3.2.3 Duration Until Enforcement Standard Compliance

The length of time until the WDNR's ES are met will be estimated, during the next phase of this project, by utilizing historical ground-water monitoring results. Dissolved organic contaminant data will be used in conjunction with aquifer testing data to evaluate the behavior of the contaminant plume. A solute transport model will be used to predict contaminant movement and concentrations.

3.2.4 Institutional Controls

A representative of the City of Kaukauna indicated they are willing to accept a Ground-Water Use Restriction.

3.2.5 Potential Receptors and Migration Pathways

Surficial soils appear to be significantly impacted. The site is currently paved and will remain paved after the proposed tank upgrading/removal. However, exposure by direct contact is possible if surficial and/or subsurface soils are exposed in the future.

Based on ground-water levels in the monitoring wells, depth to ground water on the site is approximately 3.5 to 4.5 ft bgs. The ground-water flow is interpreted to be in a southeasterly direction.

"Environmentally sensitive areas", such as wetlands and surface waters, do not appear to be located adjacent to, or immediately down gradient of, the site. A potable well is not reportedly located on the subject site and was not evident during several site inspections. FISCHER is not aware of potable wells located down gradient of, or adjacent to, the

subject site. Therefore, there do not appear to be any known potential receptors, with the possible exception of the Fox River, located approximately 600 feet northeast of the Kaukauna Maintenance Garage. However, based on ground-water levels measured to date, ground water does not appear to be flowing toward the Fox River.

A subsurface utility trench appears to be present from the 10,000 gallon USTs to the building. Soil borings were conducted on each side of this utility trench. Since contamination was detected, there is a possibility the trench is a preferential migration pathway. Subsurface utility trenches appear to be present near the waste oil UST. However, based on analytical results for samples collected from nearby borings, these trenches do not appear to be preferential migration pathways.

3.3 OTHER REMEDIAL ALTERNATIVES

As stated previously, "active treatment" can be justified as a remedial alternative at this site due to the presence of an "environmental factor", based on COMM 47. However, based on soil conditions (non-homogeneous fill overlying clay overlying bedrock), the proposed tank removal/upgrading, and an evaluation of costs, soil excavation, which is considered a "non-active source control", appears to be the most feasible.

3.4 RECOMMENDED ALTERNATIVE

Based on the information presented in the preceding sections, RNA could be a feasible alternative if source control is implemented. Based on cost estimates, FISCHER recommends soil excavation and treatment at the Ridgeview BioSite located in Whitelaw, WI and ground-water monitoring. The approximate area proposed for excavation is identified on Figure 1 and consists of approximately 1020 cubic yards of soil. Soil excavation is proposed to be conducted at the time the USTs are removed/upgraded.

The presence of USTs that may be upgraded instead of removed, the building, and subsurface utilities will limit the lateral extent of the soil excavation (not all of the soil exceeding the RCLs will be excavated). The excavation may need to be pumped if an excessive amount of ground water flows into the excavation. The depth of the excavation may be limited to no greater than seven feet in the area of the former USTs. However, in order to control ground water pumping and disposal costs, the excavation may be shallower.

Representative soil samples will be obtained from the excavation limits to document removal of affected soil. These closure samples will be analyzed for Gasoline Range Organics (GRO), Petroleum Volatile Organic Compounds (PVOC), and Diesel Range Organics (DRO). Upon completion of the closure sampling, the excavation will be backfilled to grade with imported fill. New USTs may be placed in a portion of the excavation.

If MW-1, MW-2 and/or MW-4 are removed during the excavation, one to three recovery sumps will be installed in order to monitor the ground-water at these locations after the excavation. The existing ground-water monitoring wells, existing piezometer and the newly installed sumps will be sampled for the presence of PVOC. A portion of the ground-water samples may also be analyzed for 1,2-Dichloroethane and/or Naphthalene, depending upon previous analytical results. At least

one event will include sampling for continued evaluation of RNA to see if RNA is a viable remedial method or if additional measures will need to be considered.

After one post-excavation monitoring event has been completed, FISCHER will consult with the WDNR regarding ground-water contamination within the bedrock. The WDNR may require additional bedrock piezometers. Therefore, for the purpose of this RAP, FISCHER has included the contingency to install, develop, and sample (for VOC and Dissolved Lead) three additional bedrock piezometers.

Documentation of the soil excavation and post-monitoring results will be submitted to the WDNR for review. A remediation documentation report will be submitted after the excavation phase has been completed. A subsequent submittal will include ground-water monitoring results. A request for closure or recommendations for additional monitoring will also be submitted.

It is FISCHER's opinion that "flexible" closure or closure can be requested within eight sampling events subsequent to soil excavation. Therefore, the total remedial costs for a closed remedial action are estimated to be $140,558 (Table 1). If RNA as the final remedy after source control does not appear to be feasible, based on the additional data, another remedial alternative may need to be implemented. Additional funds, if required, would be requested at that time.

4.0 LIMITATIONS OF DATA

The conclusions and recommendations of this Remedial Action Plan are formulated based on site conditions known to have existed prior to, and encountered during, field exploration activities on the site and are based on FISCHER's Site Investigation Report, dated October 2, 1998. Additional exploration and analysis is desirable, but would not be expected to significantly alter the conditions reported herein and the scope of the corrective action measures developed in the Remedial Action Plan. Estimated costs for the Remedial Action Alternatives are based on design criteria established for other sites with similar characteristics.

EXECUTIVE SUMMARY

The Kaukauna Maintenance Garage is located at 222 West 3rd Street in the City of Kaukauna, Outagamie County, Wisconsin (WI). The site presently operates as a maintenance garage and is owned by the City of Kaukauna. Four registered underground storage tanks (USTs) are located on-site: one 10,000 gallon diesel fuel, one 10,000 gallon leaded gasoline, one 10,000 gallon unleaded gasoline and one 550 gallon waste oil UST. The USTs are in use, with the exception of the UST formerly containing leaded gasoline.

OMNNI Associates (OMNNI) has been conducting a Site Investigation with regards to the waste oil UST since contamination was discovered in December of 1993. OMNNI drilled five soil borings at the site and one boring was converted into a ground-water monitoring well (MW-1). Based on review of OMNNI's Site Investigation report, dated June 1994, the extent of contamination from the waste oil UST was not yet defined at that time. Reportedly, OMNNI collected a ground-water sample from a sump located near the remaining USTs and the analytical results indicated contamination from the other USTs.

Since the City of Kaukauna is in the process of upgrading or removing the UST systems, and since OMNNI detected contamination from the diesel fuel and gasoline USTs, the City contracted Fischer Environmental, Inc. (FISCHER) to perform a Site Investigation.

As part of the Site Investigation services, 11 soil borings were drilled and four were converted into water table ground-water monitoring wells (MW-2, MW-3, MW-4 and MW-6). One of the 11 soil borings was converted into a bedrock piezometer (MW-5).

Of the soil samples exhibiting contaminant concentrations exceeding Wisconsin Department of Natural Resources' (WDNR's) generic Residual Contaminant Levels (RCLs), only samples collected from borings B-6, 1-3 feet (ft), B-8, 1-3 ft, and B-9, 1-3 ft appear to have been collected from above the subsequent water table, as measured in the ground-water monitoring wells. Petroleum compounds detected in soil samples collected beneath or at the static water table are generally considered to be dissolved in ground water. The soil zone where ground water fluctuates can be identified as the smear zone. At this site, the vadose zone appears to be the most impacted, relative to the smear zone. The extent of soil contamination, in the vadose and smear zones, appears to have been defined.

Depth to ground water on the site, based on water levels in the monitoring wells, is approximately 3.5 to 4.5 ft below ground surface (bgs). The ground-water flow is interpreted to be in a southeasterly or easterly direction.

The most recent analytical results indicate WDNR's Enforcement Standards (ES) were exceeded in ground-water monitoring wells MW-2 and MW-4 and in piezometer MW-5. The horizontal extent of ground-water contamination, based on ES exceedances, appears to have been defined. The detection of 1,2-Dichloroethane, which is generally associated with gasoline, in well MW-1 appears to indicate one ground-water contaminant plume.

Piezometer MW-5 was installed in the most impacted portion of the ground-water contaminant plume. Since Benzene was the only compound detected in piezometer MW-5 above the ES, and since it was detected at a concentration [5.5 micrograms per liter (ug/l)] only slightly exceeding the

WDNR's ES of 5 ug/l, the vertical extent of contamination will be considered defined for the purposes of this Site Investigation.

"Environmentally sensitive areas", such as wetlands and surface waters, do not appear to be located adjacent to, or immediately down gradient of, the site. A potable well is not reportedly located on the subject site and was not evident during several site inspections. It is FISCHER's opinion that contamination has been detected within one meter of bedrock. Bedrock appeared to be present on-site as shallow as 8.5 ft bgs. Therefore, an "environmental factor" appears to be present and active remedial treatment can be justified, based on review of COMM 47. A Remedial Action Plan (RAP) will be submitted under a separate cover.

SUBMITTAL CERTIFICATION

"I, Karen A. Burkman, hereby certify that I am a scientist as that term is defined in s. NR 712.03(3), Wis. Adm. Code, and that, to the best of my knowledge, all of the information contained in this document is correct and the document was prepared in compliance with all applicable requirements in chs. NR 700 to 726, Wis. Adm. Code."

1.0 INTRODUCTION

1.1 PURPOSE AND SCOPE

The purpose of this report is to fulfill WDNR requirements pertaining to Site Investigations. This report documents the Site Investigation activities, which include determining the degree and extent of soil and ground-water contamination associated with USTs at the Kaukauna Maintenance Garage facility located at 222 West 3rd Street, Kaukauna, WI.

Specific objectives of this study include:

- Review existing data regarding area and site geology, past and present land uses, and soil and ground-water contamination.
- Determine the lateral and vertical extents of petroleum-affected soils and ground water.

Site Operations: The property is used as a municipal maintenance garage.

1.3 PROJECT BACKGROUND

The Kaukauna Maintenance Garage site is owned and operated by the City of Kaukauna and currently operates as a municipal maintenance garage. Four registered USTs are located on-site: one 10,000 gallon diesel fuel, one 10,000 gallon leaded gasoline, one 10,000 gallon unleaded gasoline and one 500 or 550 gallon waste oil UST. The USTs are in use, with the exception of the UST formerly containing leaded gasoline.

OMNNI has been conducting a Site Investigation with regards to the waste oil UST since contamination was discovered in December of 1993. OMNNI drilled five soil borings at the site and one boring was converted into a ground-water monitoring well (MW-1). Based on review of OMNNI's Site Investigation report, dated June 1994, the extent of contamination from the waste oil UST was not yet defined at that time. Reportedly, OMNNI collected a ground-water sample from a sump located near the remaining USTs and the analytical result indicated contamination from the other USTs.

Since the City of Kaukauna is in the process of upgrading or removing the UST systems, and since OMNNI detected contamination from the diesel fuel and gasoline USTs, the City contracted FISCHER to perform a Site Investigation. Mr. John Sundelius, Street Superintendent for the City of Kaukauna, retained FISCHER on February 18, 1998. The contracted services included review of existing pertinent information, preparation of a Site Investigation Work Plan, performance of a Site Investigation to determine the extent of petroleum-affected soils and/or ground water, preparation of a Site Investigation Report and Remedial Action Plan, oversight of soil and ground water requiring remediation, and completion of submittals per WDNR and Department of Commerce (COMM) requirements.

2.0 SITE CHARACTERIZATION

2.1 TOPOGRAPHY AND SURFACE HYDROLOGY

Based on review of the United States Geological Survey (USGS) Kaukauna, WI Quadrangle map, dated 1974 and photorevised 1984, the elevation of the site is approximately 655+/- 5 ft above mean sea level. The Fox River is located approximately 600 feet northeast of the site. The Fox River and Kankapot Creek confluence is located approximately 2,000 ft southeast of the site.

2.2 SOILS

According to the "Soil Survey of Outagamie County, WI", the soil in the subject site area typically consists of Udorthents. This is well drained, mainly level and gently sloping soil in filled areas, where the fill is mainly loamy and clayey. The permeability varies but is mostly slow or very slow.

Local potable well construction reports and geologic logs were requested from the Geological Natural History Survey (GNHS) office located in Madison, WI. Based on three well construction reports for wells located in the site vicinity, the following formations were encountered during well installation.

- Clay 0-10 ft bgs; till 10-55 ft bgs; Dolomite 55-240 ft bgs; Sandstone 240-245 ft bgs; Dolomite 245-250 ft bgs; Sandstone 250-260 ft bgs; Dolomite 260-440 ft bgs; Siltstone 440-450 ft bgs; Dolomite 450-459 ft bgs; Shale 459-460 ft bgs; Dolomite 460-465 ft bgs; Sandstone 465-550 ft bgs; Siltstone 550-557 ft bgs
- Drift 0-8 ft bgs; Dolomite 8-172 ft bgs; Sandstone 172-228 ft bgs; Dolomite 228-403 ft bgs; Sandstone 403-733.5 ft bgs
- Clay 0-26 ft bgs; Limestone 26-353 ft bgs; Shale 353-355 ft bgs; Limestone 355-395 ft bgs; Sandstone 395-795 ft bgs; "Broken" Granite 795-806 ft bgs

Based on review of OMNNI's Soil Boring Logs previously submitted to the WDNR, in general, silt, sand and fill overlay clay on the site.

A description of subsurface conditions encountered at each boring drilled during FISCHER's Site Investigation, is shown on the Soil Boring Logs (Appendix A). The lines of demarcation on the boring logs represent an approximate boundary between the various soil classifications since the transition is likely to be more gradual. Soil descriptions are representative for the specific boring location, but variation may occur between and beyond the sampling intervals and boring locations.

The surface of the site is covered with asphalt. The soils at the site generally consist of fill to a depth ranging from approximately five to seven ft. These soils are underlain by clay with varying amounts of silt and gravel overlying silt, with varying amounts of sand and gravel, to the termination depth of the borings. A geologic cross-section is presented in Figure 4.

A hydraulic conductivity test was conducted on a soil sample collected with a Shelby tube from boring B-8 at three to five ft bgs. The result indicated a hydraulic conductivity of 2.2×10^{-7} centimeters per second (cm/sec). Soil testing results are provided in Appendix A.

2.3 GEOLOGY

Glacial geology in the site vicinity consists of lacustrine deposits. The bedrock is Ordovician age Sinnipee dolomite with some limestone and shale. Glacial sediments in the Fox-Wolf basin include morainal deposits of unsorted silt, clay, sand, and gravel; outwash deposits of sand and gravel; and lacustrine deposits consisting of mainly silt and clay. Depth to bedrock in the area appears to be between zero and 50 ft bgs.

Based on review of the aforementioned well construction reports obtained from the GNHS office, bedrock was first encountered at depths ranging from eight to ten ft bgs. According to OMNNI's Soil Boring Logs, bedrock was encountered at approximately ten ft bgs on the site.

Auger refusal, probably bedrock, was encountered in four of the borings performed by FISCHER, at approximately 8.5 and nine ft bgs. In boring B-15, weathered bedrock appeared to be encountered at approximately 8.5 ft bgs, and unweathered bedrock appeared to be encountered at approximately 13.5 ft bgs.

2.4 HYDROGEOLOGY AND POTABLE WELLS

Depth to ground water at the site is approximately 3.5 to 4.5 ft bgs, based on ground-water elevations recorded during sampling events. The ground-water flow is interpreted to be in a southeasterly or easterly direction (Figures 5 and 6). However, additional ground-water monitoring wells and measurements over a longer period of time would be required to accurately evaluate hydraulic gradients and ground-water flow direction. Ground-water flow direction and levels may fluctuate due to variations in seasonal precipitation, lateral drainage conditions, and soil permeability characteristics.

A review of the aforementioned well construction reports supplied by the GNHS office, indicated the depth to ground water ranged from 48 to 72 ft bgs during well installation. OMNNI stated in its previously submitted Site Investigation report the "depth to ground water at this site is approximately four feet."

A potable well is not reportedly located on the subject site and was not evident during several site inspections. FISCHER is unaware of potable wells located down gradient of, or adjacent to, the subject site.

3.0 SITE INVESTIGATION

3.1 GENERAL

The purpose of the Site Investigation was to delineate the area of petroleum-affected soil and ground water, and to assess public health concerns. These goals were achieved in general accordance with WDNR and COMM requirements.

3.2 SOIL INVESTIGATION

3.2.1 Soil Borings

On April 15, 1998, nine soil borings (B-6 through B-14) were drilled by Midwest Engineering Services, Inc. (MES). On August 28, 1998, two soil borings (B-15 and B-16) were drilled by STS Consultants, Ltd. (STS). The soil borings, which are identified on Figure 3, were advanced to depths ranging from five to 18 ft bgs.

The soil borings were advanced by a truck-mounted rotary drill rig utilizing either 3¼ or 4¼-inch inner diameter continuous flight hollow stem augers. Soil samples were obtained by the Standard Penetration Testing (SPT) method in general accordance with American Society for Testing Materials (ASTM) D1586 procedures at the intervals indicated on the boring logs. The SPT provides a means of estimating the relative density of granular soils and the comparative consistency of cohesive soils, thereby providing a method of evaluating the soil's relative strength and compressibility characteristics. Soil samples were visually classified in accordance with the Unified Soil Classification System. Soil Boring Logs are included in Appendix A.

Since boring B-15 was advanced into the bedrock for the purpose of installing a bedrock piezometer, care was taken to prevent contaminant drawdown. This boring was drilled using the following procedure, which was pre-approved by Mr. Dino Tsoris, representative of the WDNR. Hollow stem augers were drilled to the top of bedrock and the borehole was backfilled with 3/8" bentonite chips. A steel casing was then driven through the bentonite into the top of the bedrock to form a seal. A rock bit was then used to drill through the casing into the bedrock to the desired depth. The steel casing was later removed. Although the desired depth was 18.5 ft bgs, to allow placement of a five foot screen in the "solid" bedrock and not the weathered bedrock, the drill rig malfunctioned. Mr. Dino Tsoris was contacted regarding the situation. He approved placement of the well screen at 13 to 18 ft bgs, only 0.5 feet in the upper weathered bedrock. His approval allowed installation of the well and removal of the drill rig from the site for repairs.

Sampling tools and hollow stem augers were decontaminated prior to mobilization to the project site and clean augers were utilized for each soil boring. Sampling tools were decontaminated between each sampling event and each soil boring location. Decontamination procedures consisted of steam cleaning the augers and the use of a detergent solution and potable water rinse for the split-spoon sampling devices.

Each soil sample was placed in a clean container and later screened with a Photoionization Detector (PID), which was calibrated prior to use. The samples were

permitted to equilibrate at 70 degrees Fahrenheit for a period of at least 10 minutes, based upon the ambient outdoor temperature. The sample was then screened by inserting the probe into the headspace.

Soil samples were field screened for the presence of total volatile vapors using a Thermal Environmental Instrument, Model 580B, 10.6 eV lamp, PID. The PID is an electronic instrument that measures the relative concentration of volatile organic vapors in the headspace of a container. The response of the instrument is dependent upon compound volatility, ambient temperature, and the ionization potential of gases measured. Because the individual gases measured and their concentrations in the headspace are not known, the response of the meter only serves as a relative indicator of the presence of volatile vapor and does not provide an exact measurement of the gases present. The PID is therefore a qualitative tool and not a quantitative measuring device.

Soil cuttings were field screened to determine if they were impacted with petroleum compounds. Cuttings were placed into Department of Transportation (DOT) approved 55-gallon drums and remain on-site for future disposal. Upon completion, the soil borings not converted to ground-water monitoring wells were backfilled with bentonite chips in accordance with NR 141.25 (Appendix A).

Based on the results of field screening and visual and olfactory observations, one or two samples from each boring were selected for laboratory analysis. Soil samples collected from the borings were submitted for Gasoline Range Organics (GRO), Diesel Range Organics (DRO) and Petroleum Volatile Organic Compounds (PVOC) analyses. Soil samples collected from the following borings were also analyzed for Total Lead, B-6, B-8, B-9, and B-12. Soil samples collected from boring B-9 and B-12 were analyzed for Volatile Organic Compounds (VOC) instead of PVOC. The soil sample collected from boring B-9, at the one to three foot interval, was also analyzed for Polynuclear Aromatic Hydrocarbons (PAH).

The GRO, DRO, PVOC and VOC samples were weighed in the field with a digital scale. Approximately 25 grams of soil were placed into a clean laboratory prepared jar. Samples collected for GRO, PVOC and VOC were subsequently preserved utilizing premeasured laboratory grade methanol. All of the samples were then transported, on ice, to En Chem, Inc. (WDNR #405132750) using standard chain-of-custody procedures.

3.2.2 Soil Contamination Assessment

The WDNR has established a reporting and action level of 10 milligrams per kilogram (mg/kg) GRO and DRO. If this level is exceeded, an investigation, to evaluate the extent of contamination, will generally be required. The action level is not usually considered a cleanup standard. The WDNR currently utilizes an RCL for GRO and DRO in soil of 100 mg/kg or 250 mg/kg, depending on the hydraulic conductivity of the soil. An RCL of 250 mg/kg will be utilized for this site, based on a hydraulic conductivity test result of 2.2×10^{-7} cm/sec.

The WDNR has also established RCLs for Total Lead and various VOC that present a human or environmental health hazard. When these levels are exceeded, remedial action

may be required. The RCLs may be used as Soil Cleanup Standards, however the WDNR does allow the development of Site Specific Soil Cleanup Standards.

Soil samples obtained during the field exploration were field screened using a PID. The results are presented on the boring logs (Appendix A). The results indicated the presence of total organic vapors significantly exceeding background readings in borings B-8, B-9, B-12, and B-15. Based on these PID results and the apparent water table, 18 soil samples were selected for laboratory analysis. Analytical results are presented in Appendix B and are summarized in Table 1. A summary of the analytical results for soil borings drilled by OMNNI are presented in Table 2.

GRO and DRO were not detected in any of the soil samples at concentrations exceeding the WDNR's RCL of 250 mg/kg, except in the two samples collected from boring B-15. Lead was detected at concentrations exceeding the RCL of 50 mg/kg in samples collected from borings B-6 (one to three ft) and B-9 (one to three ft). PAH were detected at concentrations exceeding the Limits of Detection (LOD). However, RCLs for PAH are not yet established. PVOC and VOC were detected in concentrations exceeding the WDNR's RCLs in the following soil samples: B-8, 1-3 ft; B-9, 1-3 ft; B-9, 3-5 ft; B-10, 5-7 ft; B-12, 5-7 ft; B-15, 2.5-4.5 ft; and B-15, 4.5-6.5 ft.

Of those samples having contaminant concentrations exceeding RCLs, only samples B-6, 1-3 ft; B-8, 1-3 ft; and B-9, 1-3 ft appeared to be collected from above the subsequent water table, as measured in the ground-water monitoring wells. Petroleum compounds detected in soil samples collected beneath or at the static water table are generally considered to be dissolved in ground water. The soil zone where ground water fluctuates can be identified as the smear zone. At this site, the vadose zone appears to be the most impacted, relative to the smear zone. The extent of soil contamination, in the vadose and smear zones, appears to have been defined (Figure 7).

3.3 GROUND-WATER INVESTIGATION

3.3.1 Ground-Water Monitoring Wells

Three ground-water monitoring wells were installed on-site on April 15, 1998 (MW-2 through MW-4) by MES and two were installed on-site on August 28, 1998 by STS in general accordance with NR 141 (Figure 3). MW-1 had been installed in March 1994 by OMNNI. Wells installed with FISCHER's oversight were constructed with five or ten feet of two-inch diameter polyvinyl chloride (PVC) screen with 0.010-inch machine slots, and 2-inch diameter PVC flush-threaded riser pipe extending to the top of the borehole. Well screen and riser pipes were inserted into the borehole through the center of the auger during its progressive removal.

A sand filter pack was poured around the screen to approximately six inches above the screen joint. The sand filter pack did not extend above the top of the well screen in piezometer MW-5 to create a better surface seal. Approximately six inches of fine silica sand was poured above the filter pack in well MW-2. Fine silica sand was not used in construction of wells MW-3 and MW-4 due to a high water table. Fine silica sand was also not used in construction of piezometer MW-5 in order to create a surface seal to the top of

bedrock. The remaining annular space was filled to within approximately one foot of the ground surface with bentonite chips. The well top was covered by a flush-mounted protective cover. An expandable cap was fitted onto the top of the well riser and the cap was fitted with a lock. Monitoring Well Construction Forms are presented in Appendix C.

Monitoring wells MW-2 through MW-4 were developed on April 17, 1998, while well MW-6 and piezometer MW-5 were developed on August 28, 1998. Monitoring well MW-1 reportedly was developed on March 31, 1994 by OMNNI. Monitoring wells MW-2, MW-3, MW-4 and MW-6 and piezometer MW-5 were developed first surging with a block and then purging with an electric submersible pump until the wells purged "dry" three times (MW-5 did not purge "dry"). Monitoring Well Development Forms are included in Appendix C. The development tools were decontaminated between wells with a detergent solution and potable water rinse.

Monitoring well MW-1 was sampled on April 12, 1994, January 23, 1995 and September 26, 1995 by OMNNI. All of the wells (MW-1 through MW-4) were sampled on April 21 and June 5, 1998 by FISCHER. Piezometer MW-5 and well MW-6 were sampled on August 28, 1998.

During the April 21, 1998 sampling event, ground-water samples collected from monitoring wells MW-2 through MW-4 were analyzed for VOC and Dissolved Lead and the sample obtained from well MW-1 was analyzed for PVOC. On April 21, 1998, a sample from well MW-4 was also analyzed for PAH.

Ground-water samples collected from four wells (MW-1 through MW-4) were analyzed for PVOC during the June 5, 1998, sampling event. During the June 5 sampling event, a sample obtained from well MW-1 was also analyzed for 1,2-Dichloroethane (1,2-DCA) and a sample collected from well MW-4 was also analyzed for Naphthalene.

On August 28, 1998, ground-water samples were collected from piezometer MW-5 and well MW-6 for VOC and Dissolved Lead analyses.

Prior to ground-water sampling, the wells were purged "dry" three times utilizing a submersible electric pump (piezometer MW-5 did not purge 'dry"). The ground-water samples were collected from each well with a separate disposable polyethylene bailer and disposable nylon string. Samples for PVOC or VOC analyses were transferred directly from the bailer to 40-milliliter (ml) glass vials and sealed with Teflon caps. Each vial was preserved with 1:1 Hydrochloric Acid. Samples for Dissolved Lead were transferred to 250 ml plastic containers, after field filtering with a 45 micron disposable filter, and preserved with nitric acid. All samples were placed on ice and transported to EnChem, Inc. following standard chain-of-custody procedures.

3.3.2 Ground-Water Contamination Assessment

The WDNR has established Ground-Water Quality Standards in Section NR 140.10 of the Wisconsin Administrative Code. Enforcement Standards and Preventive Action Limits (PALs) have been established for Lead and several VOC of concern to the public health, as determined by the WDNR. If the ES or PAL for a given compound in ground water is exceeded, the WDNR is authorized to take action to restore ground-water quality.

Exceeding an ES may warrant active ground-water remediation, whereas exceedance of a PAL may not require active remediation.

Analytical reports are presented in Appendix D. A summary of the analytical results is presented in Table 3, which includes a graphical presentation.

In well MW-1, Methyl-tert-Butyl Ether (MTBE) was detected at a concentration exceeding the PAL during the initial April 12, 1994 sampling event. During the four subsequent sampling rounds, MTBE was not detected at concentrations above the PAL. 1,2-DCA was detected at concentrations exceeding the PAL during the first two and most recent sampling events. The 1,2-DCA concentration detected during the September 26, 1995 event exceeded WDNR's ES. The concentrations of 1,2-DCA detected during sampling events conducted over a four year timeframe appear to be relatively stable (4.9, 4.7, 7.8 and 4.0 ug/l).

Benzene was detected in ground-water samples collected from well MW-2 at concentrations exceeding the ES during both sampling rounds. MTBE concentrations detected during both sampling events were above the PAL. Concentrations of both of these compounds appear to be relatively stable.

VOC/PVOC were not detected above the LOD in ground-water samples collected from well MW-3 during both sampling events. Dissolved Lead was not detected above the LOD in well MW-3 during the initial sampling event (it was not analyzed for during the most recent event).

In well MW-4, Benzene, Naphthalene and Xylenes were detected at concentrations exceeding WDNR's ES during both sampling events. Ethylbenzene and MTBE were detected at concentrations, during both sampling rounds, exceeding the PALs. However, the initial concentration of MTBE detected was "flagged" by the chemist, meaning it is present but the actual concentration may be slightly different than that reported. The concentrations of all five of these compounds appear relatively stable.

In the ground-water ample collected from piezometer MW-5, Benzene was detected at a concentration (5.5 ug/l) only slightly exceeding the WDNR's ES of 5 ug/l during the August 28, 1998 sampling event. Chloroform was detected at a concentration exceeding the WDNR's PAL, but the chemist "flagged" the result. Ethylbenzene, Toluene, Xylenes, Trimethylbenzenes, Naphthalene and four other VOC were detected above the LOD but not above the WDNR's PAL or ES, where established (two of these compounds were "flagged" by the chemist). Dissolved Lead was not detected above the LOD.

During the August 28, 1998 sampling event, Dissolved Lead and VOC were not detected above the LOD in a ground-water sample collected from monitoring well MW-6.

The horizontal extent of petroleum-impacted ground water exceeding WDNR's Enforcement Standards appears to have been defined and is estimated on Figure 8. The detection of 1,2-Dichloroethane, which is generally associated with gasoline, in well MW-1 appears to indicate one ground-water contaminant plume.

Piezometer MW-5 was installed in the most impacted portion of the ground-water contaminant plume. Since Benzene was the only compound detected in piezometer MW-

5 and since it was detected at a concentration (5.5 ug/l) only slightly exceeding the WDNR's ES of 5 ug/l, the vertical extent of contamination will be considered defined for the purposes of this Site Investigation.

3.4 DISCUSSIONS, CONCLUSIONS AND RECOMMENDATIONS

Based on observations, field screening and comparison of the analytical results to the WDNR's RCLs, the extent of petroleum-affected soil appears to have been defined (Figure 7). Results of the investigation indicate approximately 1300 cubic yards of impacted soil, exceeding WDNR's RCLs, are present in the vadose zone and smear zone, assuming an average thickness of seven ft.

Based on ground-water analytical results in comparison to WDNR's Enforcement Standards, the extent of petroleum-affected ground water appears to have been defined (Figure 8). At this time, the ground-water contaminant plume appears to be relatively stable (Table 3). The extent of ground-water contamination within the bedrock may be defined, depending upon contaminant concentration detected in piezometer MW-5 in the future. Based on the contaminant concentrations detected in piezometer MW-5 thus far, and discussions with Mr. Dino Tsoris of the WDNR, the WDNR may not require additional bedrock wells in the future.

There may be exposure by direct contact if surficial and/or subsurface soils near the USTs are excavated in the future. The UST area and the majority of the subject site are paved and will be paved after the USTs are upgraded/removed, which reduces surface water infiltration into the impacted soils.

A subsurface utility trench appears to be present from the 10,000 gallon USTs to the building. Soil borings were drilled on each side of this utility trench. Since contamination was detected, there is a possibility the trench is a preferential migration pathway. Subsurface utility trenches appear to be present near the waste oil UST. However, based on analytical results for samples collected from nearby borings, these trenches do not appear to be preferential migration pathways.

"Environmentally sensitive areas", such as wetlands and surface waters, do not appear to be located adjacent to, or immediately down gradient of, the site. A potable well is not reportedly located on the subject site and was not evident during several site inspections. FISCHER is not aware of potable wells located down gradient of, or adjacent to, the subject site. Therefore, there do not appear to be any known potential receptors, with the possible exception of the Fox River, located approximately 600 feet northeast of the Kaukauna Maintenance Garage.

In a previous report, OMNNI indicated bedrock was encountered at the site at ten ft bgs. During FISCHER's Site Investigation, auger refusal, probably bedrock, was encountered at 8.5 to nine ft bgs. In boring B-15, weathered bedrock appeared to be encountered at approximately 8.5 ft bgs, and unweathered bedrock appeared to be encountered at approximately 13.5 ft bgs. Soil contamination has been detected in samples collected from seven ft bgs and ground-water contamination has been detected in monitoring wells screened just above what appears to be bedrock. One of the COMM 47 "environmental factors" is presence of contamination within one

meter (three feet) of bedrock. It is FISCHER's opinion that contamination has been detected within one meter of bedrock. Therefore, an "environmental factor" appears to be present and active remedial treatment can be justified, based on review of COMM 47.

Remedial alternatives will be addressed in a Remedial Action Plan, which will be submitted as a separate report.

4.0 LIMITATIONS OF DATA

The conclusions of this Site Investigation Report are formulated based on site conditions known to have existed prior to, and encountered during, field exploration activities on the site. Additional exploration and analysis is desirable, but would not be expected to significantly alter the conditions reported herein and the scope of the corrective action measures developed in the Remedial Action Plan.

WELL/DRILLHOLE/BOREHOLE INFORMATION

(3) Original Well/Drillhole/Borehole Construction Completed On
(Date) *4/15/98*

- ☐ Monitoring Well
- ☐ Water Well
- ☐ Drillhole
- ☒ Borehole

Construction Report Available? ☒ Yes ☐ No

Construction Type:
☒ Drilled ☐ Driven (Sandpoint) ☐ Dug
☐ Other (Specify)

Formation Type:
☒ Unconsolidated Formation ☐ Bedrock

Total Well Depth (ft.) *5* (From groundsurface) Casing Diameter (ins.)

Casing Depth (ft.)

Was Well Annular Space Grouted? ☐ Yes ☒ No ☐ Unknown
If Yes, To What Depth? *Feet*

(4) Depth to Water (Feet)

Pump & Piping Removed?	☐ Yes	☐ No	☒ Not Applicable
Liner(s) Removed?	☐ Yes	☐ No	☒ Not Applicable
Screen Removed?	☐ Yes	☐ No	☒ Not Applicable
Casing Left in Place?	☐ Yes	☒ No	

If No, Explain

Was Casing Cut Off Below Surface?	☐ Yes	☒ No
Did Sealing Material Rise to Surface?	☒ Yes	☐ No
Did Material Settle After 24 Hours?	☐ Yes	☒ No
If Yes, Was Hole Retopped?	☐ Yes	☐ No

(5) Required Method of Placing Sealing Material
☐ Conductor Pipe-Gravity ☐ Conductor Pipe-Pumped
☐ Dump Bailer ☒ Other (Explain) *Gravity*

(6) Sealing Materials
- ☐ Neat Cement Grout
- ☐ Sand-Cement (Concrete)Grout
- ☐ Concrete
- ☐ Clay-Sand Slurry
- ☐ Bentonite-Sand Slurry
- ☒ Chipped Bentonite

For monitoring wells and monitoring well boreholes only
- ☐ Bentonite Pellets
- ☐ Granular Bentonite
- ☐ Bentonite-Cement Grout

(7) Sealing Material Used	From (Ft.)	To (Ft.)	No. Yards, Sacks Sealant or Volume	Mix Ratio or Mud Weight
3/8" Chipped Bentonite	*Surface*	*5*	*1 Bag*

WELL/DRILLHOLE/BOREHOLE ABANDONMENT
Form 3300-5B Rev. 12-91

All abandonment work shall be performed in accordance with the provisions of Chapters NR 111, NR 112 or NR 141, Wis. Admin. Code, whichever is applicable. Also, see instructions on back.

(1) GENERAL INFORMATION

Well/Drillhole/Borehole Location: *B-14*
County: *Outagamie*
Section Location: *N 1/4 of Gov. Lot 22, T 21N, R 18E*
(If applicable) Gov't Lot / Grid Number
Grid Location: *Feet S, Feet W*
Civil Town Name:
Street Address of Well: *222 W. 3rd Street*
City, Village: *Kaukauna, WI 54130*

(2) FACILITY NAME

Original Well Owner (If Known): *Kaukauna Maintenance Garage*
Present Well Owner: *Same as above*
Street or Route: *222 W. 3rd Street*
City, State, Zip Code: *Kaukauna, WI*
Facility Well No. and/or Name (If Applicable):
WI Unique Well No.:
Reason For Abandonment: *No longer needed*
Date of Abandonment: *4/15/98*

WELL/DRILLHOLE/BOREHOLE INFORMATION

(3) Original Well/Drillhole/Borehole Construction Completed On
(Date) *4/15/98*

- ☐ Monitoring Well
- ☐ Water Well
- ☐ Drillhole
- ☒ Borehole

Construction Report Available? ☒ Yes ☐ No

Construction Type:
☒ Drilled ☐ Driven (Sandpoint) ☐ Dug
☐ Other (Specify)

Formation Type:
☒ Unconsolidated Formation ☐ Bedrock

Total Well Depth (ft.) *5* Casing Diameter (ins.) _____
(From groundsurface)

Casing Depth (ft.) _____

Was Well Annular Space Grouted? ☐ Yes ☒ No ☐ Unknown
If Yes, To What Depth? *Feet*

(4) Depth to Water (Feet) _____

Pump & Piping Removed?	☐ Yes	☐ No	☒ Not Applicable
Liner(s) Removed?	☐ Yes	☐ No	☒ Not Applicable
Screen Removed?	☐ Yes	☐ No	☒ Not Applicable
Casing Left in Place?	☐ Yes	☒ No	

If No, Explain

Was Casing Cut Off Below Surface?	☐ Yes	☒ No
Did Sealing Material Rise to Surface?	☒ Yes	☐ No
Did Material Settle After 24 Hours?	☐ Yes	☒ No
If Yes, Was Hole Retopped?	☐ Yes	☐ No

(5) Required Method of Placing Sealing Material
☐ Conductor Pipe-Gravity ☐ Conductor Pipe-Pumped
☐ Dump Bailer ☒ Other (Explain) *Gravity*

(6) Sealing Materials
- ☐ Neat Cement Grout
- ☐ Sand-Cement (Concrete)Grout
- ☐ Concrete
- ☐ Clay-Sand Slurry
- ☐ Bentonite-Sand Slurry
- ☒ Chipped Bentonite

For monitoring wells and monitoring well boreholes only
- ☐ Bentonite Pellets
- ☐ Granular Bentonite
- ☐ Bentonite-Cement Grout

(7) Sealing Material Used	From (Ft.)	To (Ft.)	No. Yards, Sacks Sealant or Volume	Mix Ratio or Mud Weight
3/8" Chipped Bentonite	*Surface*	*5*	*1 Bag*

Report Of Falling Head Hydraulic Conductivity Test

Client: Fischer Environmental

Project: Kaukauna Maintenance Garage
222 West 3rd Street
Kaukauna, Wisconsin 54130

Date: 5/1/98

Project No.: 3-83060

Laboratory No.: IOB98024
Sample Location: B-8, 3.0-5.0 Ft.
Sample Description: Yellowish Brown Silty Clay, tracesand, trace gravel

Material Properties

Natural Moisture:	---	Percent Finer No 200:	-----
Specific Gravity:	-----	Percent Finer .005 mm:	-----
Max. Dry Density:	---	Liquid Limit:	-----
Optimum Moisture	-----	Plasiticity Index.	-----

Sample Characteristics

Height,cm:	8.09
Diameter,cm:	7.13
Wet Weight,gm:	639.2
Moisture, %:	25.2
Dry Density,pcf:	98.4
Compaction, %:	---

Test Parameters

Permeameter:	Flexible Wall
Permeant Fluid:	Deaired Water
Cell Pressure:	45
Back Pressure:	39
Test Pressure:	42
Differential Head	3

(Hydraulic Conductivity,ASTM D5084,method C)

Run No.	Time t (sec)	Head Loss, cm ho	hi	Inflow/ Outflow	Coeff. of Permeability, cm/sec k=aL/2At[ln(ho/hi)]

The "Q" flag is present when a parameter has been detected below the LOQ. This indicates the results are qualified due to the uncertainty of the parameter concentration between the LOD and the LOQ.

Soil VOC detects are corrected for the total solids, unless otherwise noted.

I certify that the data contained in this Final Report has been generated and reviewed in accordance with approved methods and Laboratory Standard Operating Procedure. Exceptions, if any, are discussed in the accompanying sample narrative. Release of this final report is authorized by Laboratory management, as is verified by the following signature.

Lab#:	TestGroupID:	Comment:
882112-002 B-6, 1-3 FT	PVOC-S-ME	The presence of 1,3,5-Trimethylbenzene was confirmed on 4/27/98 by a GC/MS analysis.
	PVOC-S-ME	The presence of 1,2,4-Trimethylbenzene was confirmed on 4/27/98 by a GC/MS analysis.
	DRO-S	Peaks present late in and beyond window.
882112-004 B-8, 1-3 FT	GRO-S-ME	Sample exhibits hydrocarbon pattern resembling gasoline. Early and late peaks were present outside of window.
	DRO-S	Late eluting peaks present along with diesel range peaks.
882112-005 B-9, 1-3 FT	GRO-S-ME	The PVOC surrogate recovery was above limits due to co-elution with non-target compounds.
	GRO-S-ME	Sample exhibits hydrocarbon pattern resembling gasoline. Early peaks were present outside of window.
	DRO-S	Front peaks and late eluting peaks present in the chromatogram.
882112-006 B-9, 3-5 FT	GRO-S-ME	Sample has a typical gas pattern.
882112-007 B-10, 1-3 FT	PVOC-S-ME	The presence of 1,2,4-Trimethylbenzene was confirmed on 4/27/98 by a GC/MS analysis.
	DRO-S	Peaks present late in and beyond window.
882112-008 B-10, 5-7 FT	GRO-S-ME	Low level peaks present in chromatogram.
	DRO-S	Peaks present late in and beyond window.
882112-009 B-11, 1-3 FT	DRO-S	Peaks present late in and beyond window.
882112-011 B-12, 1-3 FT	DRO-S	Late eluting peaks present along with diesel range peaks.
	GRO-S-ME	Low level peaks present in chromatogram.
882112-012 B-12, 5-7 FT	DRO-S	Front peaks present along with mainly diesel peaks.
	GRO-S-ME	Sample exhibits hydrocarbon pattern resembling gasoline. Early and late peaks were present outside of window.
882112-013 B-13, 1-3 FT	DRO-S	Late eluting peaks present along with diesel range peaks.
	GRO-S-ME	Low level peaks present in chromatogram.
	PVOC-S-ME	The presence of 1,3,5-Trimethylbenzene was confirmed on 4/21/98 by a GC/MS analysis.

The "Q" flag is present when a parameter has been detected below the LOQ. This indicates the results are qualified due to the uncertainty of the parameter concentration between the LOD and the LOQ.

Soil VOC detects are corrected for the total solids, unless otherwise noted.

I certify that the data contained in this Final Report has been generated and reviewed in accordance with approved methods and Laboratory Standard Operating Procedure. Exceptions, if any, are discussed in the accompanying sample narrative. Release of this final report is authorized by Laboratory management, as is verified by the following signature.

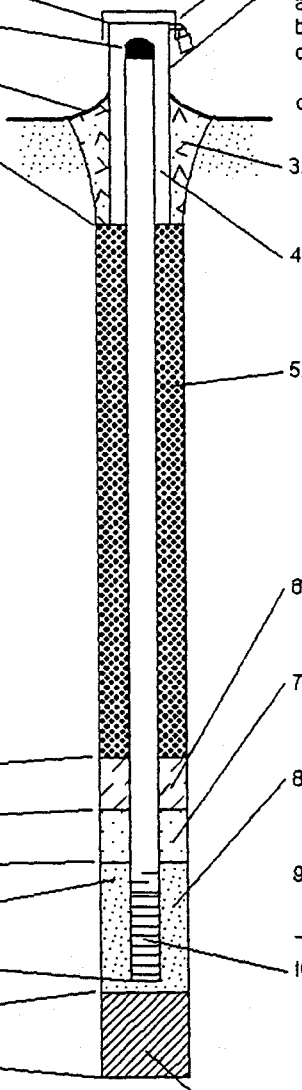
Is Well A Point of Enforcement Std. Application? ☒ Yes ☐ No		

A. Protective pipe, top elevation _____ ft. MSL
B. Well casing, top elevation _____ ft. MSL
C. Land surface elevation _____ ft. MSL
D. Surface seal, bottom _____ ft. MSL or 1 ft.

12. USCS Classification of soil near screen:
GP ☐ GM ☒ GC ☐ GW ☐ SW ☐ SP ☐
SM ☐ SC ☐ ML ☐ MH ☐ CL ☒ CH ☐
Bedrock ☐

13. Sieve analysis attached? ☐ Yes ☒ No



14. Drilling method used: Rotary ☐ 50
Hollow Stem Auger ☒ 41
_____ Other ☐

15. Drilling fluid used: Water ☐ 02 Air ☐ 01
Drilling Mud ☐ 03 None ☒ 99

16. Drilling additives used? ☐ Yes ☒ No
Describe _____

17. Source of water *(attach analysis)*:
_____

E. Bentonite seal, top _____ ft. MSL or 1 ft.
F. Fine sand, top _____ ft. MSL or 2 ft.
G. Filter pack, top _____ ft. MSL or 2.5 ft.
H. Screen joint, top _____ ft. MSL or 3 ft.
I. Well bottom _____ ft. MSL or 13 ft.
J. Filter pack, bottom _____ ft. MSL or 13.5 ft.
K. Borehole, bottom _____ ft. MSL or 13.5 ft.
L. Borehole, diameter 8 in.
M. O.D. well casing 2.25 in.
N. I.D. well casing 2.049 in.

1. Cap and lock? ☒ Yes ☐ No
2. Protective cover pipe:
a. Inside diameter: 8 in.
b. Length: 1 ft.
c. Material: Steel ☒ 04
Flushmount Other ☒
d. Additional protection? ☒ Yes ☐ No
If yes, describe: Locking Expandable Cap
3. Surface seal: Bentonite ☐ 30
Concrete ☒ 01
_____ Other ☐
4. Material between well casing and protective pipe:
Bentonite ☒ 30
Annular space seal ☐
_____ Other ☐
5. Annular space seal: a. Granular Bentonite ☐ 33
b. ____ Lbs/gal mud weight .....Bentonite-sand slurry ☐ 35
c. ____ Lbs/gal mud weight ..... Bentonite slurry ☐ 31
d. ____ % Bentonite .....Bentonite-cement grout ☐ 50
e. ____ Ft^3 volume added for any of the above
f. How installed: Tremie ☐ 01
Tremie pumped ☐ 02
Gravity ☒ 08
6. Bentonite seal: a. Bentonite Granules ☐ 33
b. ☐ 1/4 in. ☐ 3/8 in. ☐ 1/2 in. Bentonite pellets ☐ 32
c. 3/8" Chipped Bentonite Other ☒ x
7. Fine sand material: Manufacturer, product name and mesh size
a. Red Flint 45/55
b. Volume added 0.33 ft^3
8. Filter pack material: Manufacturer, product name and mesh size
a. #30 Red Flint
b. Volume added 3.3 ft^3
9. Well casing: Flush threaded PVC schedule 40 ☒ 23
Flush threaded PVC schedule 80 ☐ 24
_____ Other ☐
10. Screen material: PVC
a. Screen type: Factory cut ☒ 11
Continuous slot ☒ 01
_____ Other ☐
b. Manufacturer Diedrich
c. Slot size: 0.010 in.
d. Slotted length: 10 ft.
11. Backfill material (below filter pack): None ☒ 14
_____ Other ☐

The "Q" flag is present when a parameter has been detected below the LOQ. This indicates the results are qualified due to the uncertainty of the parameter concentration between the LOD and the LOQ.

Soil VOC detects are corrected for the total solids, unless otherwise noted.

I certify that the data contained in this Final Report has been generated and reviewed in accordance with approved methods and Laboratory Standard Operating Procedure. Exceptions, if any, are discussed in the accompanying sample narrative. Release of this final report is authorized by Laboratory management, as is verified by the following signature.

The "Q" flag is present when a parameter has been detected below the LOQ. This indicates the results are qualified due to the uncertainty of the parameter concentration between the LOD and the LOQ.

Soil VOC detects are corrected for the total solids, unless otherwise noted.

I certify that the data contained in this Final Report has been generated and reviewed in accordance with approved methods and Laboratory Standard Operating Procedure. Exceptions, if any, are discussed in the accompanying sample narrative. Release of this final report is authorized by Laboratory management, as is verified by the following signature.

The "Q" flag is present when a parameter has been detected below the LOQ. This indicates the results are qualified due to the uncertainty of the parameter concentration between the LOD and the LOQ.

Soil VOC detects are corrected for the total solids, unless otherwise noted.

I certify that the data contained in this Final Report has been generated and reviewed in accordance with approved methods and Laboratory Standard Operating Procedure. Exceptions, if any, are discussed in the accompanying sample narrative. Release of this final report is authorized by Laboratory management, as is verified by the following signature.

FROM: Dino Tsoris

SUBJECT: Site Investigation City of Kaukauna Garage

Karen Burkman of Fischer Environmental contacted me to discuss the potential for installing a piezometer at the site. Bedrock is at a depth of ~ 10 BGL, groundwater is reportedly at a depth of 2-3 BGL and soil and groundwater contamination has been detected in the shallow zone. A piezometer located in proximity of the hot zone should be installed to determine the extent of contamination. The city of Kaukauna is upgrading the site and soil remediation, by excavation, is expected to be conducted within 60 days. I told Karen that it would be appropriate to install the piezometer after the site upgrades and soil remediation; the delay would prevent the potential of having to remove or damage the well during soil remediation activites.

Dear Mr. Tsoris:

On behalf of Mr. John Sundelius, Street Superintendent for the City of Kaukauna, Fischer Environmental Consulting, LLC. (FISCHER) is pleased to submit this Site Investigation Work Plan, which has been designed to investigate the extent of petroleum-affected soils and/or ground water at the above referenced site. In following Wisconsin Department of Natural Resources (WDNR) Guidance for Conducting Environmental Response Actions, a phased approach is being recommended to reduce costs.

If you have any questions, or wish to discuss any part of this plan, we would be pleased to do so at your earliest convenience.

Respectfully submitted,

FISCHER ENVIRONMENTAL CONSULTING, LLC.

Karen A. Burkman
Senior Project Manager

1.0 INTRODUCTION

1.1 PURPOSE

The purpose of this report is to inform the WDNR of the proposed Site Investigation activities, and to fulfill WDNR and Wisconsin Department of Commerce (COMM) requirements pertaining to the release at the Kaukauna Maintenance Garage site. This Site Investigation Work Plan outlines FISCHER's initial proposed investigative phase for this project. In addition, this work plan will provide the philosophy for continued investigation and possible remediation. This Site Investigation Work Plan has been prepared in general accordance with NR 716.09, Wisconsin Administrative Code.

The purpose of the Site Investigation is to determine the degree and type of contamination and to define the horizontal and vertical extent of impacted soil and/or ground water. After data has been collected and results have been reviewed, FISCHER will compare the soil analytical results to WDNR's generic Residual Contaminants Levels and the ground-water analytical results to WDNR's Enforcement Standards and Preventive Action Limits in order to define the extent of petroleum contamination. FISCHER will also make the necessary recommendations for remediation or closure. Upon completion of the Site Investigation, a Site Investigation Report and Remedial Action Plan (RAP) will be prepared and submitted to the WDNR. The Site Investigation will be performed, and the subsequent report will be prepared, in general accordance with WDNR and COMM guidelines and regulations, such as NR 141 and NR 700's, Wisconsin Administrative Code.

1.2 BACKGROUND

Kaukauna Maintenance Garage is located within the N ¼ of Government Lot 22, Township 21N, Range 18E in Outagamie County (Figure 1 - Site Location Map and Figure 2 - Site Plan). Specifically, the site is located at 222 West 3rd Street in Kaukauna, Wisconsin (WI). The site is utilized as a maintenance garage and is currently owned by the City of Kaukauna. Four (4) underground storage tanks (USTs) are located on the subject property. The USTs are in use, with the exception of the UST containing leaded gasoline (Table 1 - Tank Descriptions).

OMNNI Associates has been conducting a Site Investigation with regards to the waste oil UST, since contamination was discovered in December of 1993 [Leaking Underground Storage Tank (LUST) ID #45-1729]. Based on preliminary review of OMNNI Associates' Site Investigation report, the extent of contamination from the waste oil UST has not yet been defined. Reportedly, OMNNI collected a ground water sample from a sump located near the remaining USTs and the analytical result indicated contamination from the other USTs.

FISCHER was retained by Mr. John Sundelius, Street Superintendent for the City of Kaukauna, on February 18, 1998 to review all pertinent information pertaining to the subject site, prepare a Site Investigation Work Plan to be submitted to the WDNR, perform a Site Investigation to determine the extent of petroleum affected soils and/or ground water, prepare and submit a Site Investigation Report and RAP, and to oversee the remediation of soils and/or ground water requiring remediation per WDNR guidelines and regulations.

Mr. Dino Tsoris, with the WDNR, indicated the same LUST ID number could be used at this time. However, if two (2) separate plumes are detected during FISCHER's Site Investigation activities, a separate LUST ID number will be obtained at that time.

2.0 SITE LOCATION AND CONTACTS

Site Name and Location:	Kaukauna Maintenance Garage 222 West 3rd Street Kaukauna, WI 54130 N ¼ of Government Lot 22, Township 21N, Range 18E in Outagamie County (Figure 1 – Site Location Map)
Site Operations:	The site is used as a municipal maintenance garage.
Responsible Party:	City of Kaukauna Department of Public Works P.O. Box 890 Kaukauna, WI 54130-0890 Contact: Mr. John Sundelius – Street Superintendent Phone: (920) 766-337
Consultant:	Fischer Environmental Consulting, LLC. P.O. Box 127 Kaukauna, WI 54130 Phone: (920) 766-2069
Project Manager:	Ms. Karen A. Burkman Fischer Environmental Consulting, LLC. P.O. Box 127 Kaukauna, WI 54130 Phone: (920) 766-2069
Project Hydrogeologist:	Mr. Jeffrey L. Fischer Fischer Environmental Consulting, LLC. P.O. Box 552 Ripon, WI 54971 Phone: (920) 745-2200
Contractors:	Analytical and drilling contractors to be selected.

3.0 PHYSIOGRAPHICAL AND GEOLOGIC INFORMATION

3.1 TOPOGRAPHY AND SURFACE HYDROLOGY

A 1974, photorevised 1984, United States Geological Survey (USGS) topographic map (Kaukauna Quadrangle) was reviewed. Based on this review, the site is nearly level with an elevation of approximately 655 +/- 5 feet above mean sea level. The Fox River is located approximately 600 feet northeast of the site. The Fox River and Kankapot Creek confluence is located approximately 2,000 feet southeast of the site.

3.2 SOILS

According to the "Soil Survey of Outagamie County, WI", the soil in the subject site area typically consists of Udorthents. This is well drained, mainly level and gently sloping soil in filled areas, where the fill is mainly loamy and clayey. The permeability varies but is mostly slow or very slow.

Local potable well construction reports and geologic logs were requested from the Geological Natural History Survey (GNHS) office located in Madison, Wisconsin. Based on three (3) well construction reports for wells located in the site vicinity, the following formations were encountered during well installation.

- Clay 0-10 feet (ft) below ground surface (BGS); till 10-55 ft BGS; Dolomite 55-240 ft BGS; Sandstone 240-245 ft BGS; Dolomite 245-250 ft BGS; Sandstone 250-260 ft BGS; Dolomite 260-440 ft BGS; Siltstone 440-450 ft BGS; Dolomite 450-459 ft BGS; Shale 459-460 ft BGS; Dolomite 460-465 ft BGS; Sandstone 465-550 ft BGS; Siltstone 550-557 ft BGS
- Drift 0-8 ft BGS; Dolomite 8-172 ft BGS; Sandstone 172-228 ft BGS; Dolomite 228-403 ft BGS; Sandstone 403-733½ ft BGS
- Clay 0-26 ft BGS; Limestone 26-353 ft BGS; Shale 353-355 ft BGS; Limestone 355-395 ft BGS; Sandstone 395-795 ft BGS; "Broken" Granite 795-806 ft BGS

Based on review of OMNNI's Soil Boring Logs previously submitted to the WDNR, in general, silt, sand and fill overlay clay on the site. Site specific soil information will be obtained by visual classification of soil samples collected during the Site Investigation and preparation of Soil Boring Logs.

3.3 GEOLOGY

Glacial geology in the site vicinity consists of glacial lake basins. The bedrock in the site area is comprised of Ordivician Formation, Sinnipee Group dolomite with some limestone and shale.

Local potable well construction reports and geologic logs were requested from the GNHS office located in Madison, Wisconsin. Based on review of the aforementioned well construction reports, bedrock was first encountered between eight (8) and ten (10) ft BGS in three (3) wells. According to OMNNI's Soil Boring Logs, bedrock was encountered at approximately ten (10) ft BGS on the site.

3.4 HYDROGEOLOGY AND POTABLE WELLS

Based on review of a topographic map, the general ground-water flow direction in the site vicinity is to the north or northeast, towards the Fox River. Precipitation, location of roads etc. and the elevation of nearby river levels may affect ground-water flow direction. At least three (3) ground-water monitoring wells would be needed to obtain a site specific ground-water flow direction.

Based on the three (3) aforementioned well construction reports, the depth to ground water ranged from 48 to 72 ft BGS. OMNNI stated in its previously submitted Site Investigation report the "depth to ground water at this site is approximately four (4) feet."

A review of the well construction reports supplied by the GNHS office indicated four (4) potable wells may be present with a ¼-mile radius of the site. The wells were installed prior to 1946, with the exception of one (1) well installed in 1974. Therefore, there is the possibility that not all of these four (4) wells are still present or in use. There did not appear to be any well construction reports for potable wells located on, or adjacent to, the subject site.

Additional information regarding the depth to ground water, flow direction of ground water and presence of on-site or nearby potable wells may be obtained during the Site Investigation.

3.5 POTENTIAL MIGRATION PATHWAYS AND IMPACTS TO RECEPTORS

During the Site Investigation, FISCHER will attempt to identify potential migration pathways, such as subsurface utility trenches. At this time, FISCHER is not aware of any receptors, such as potable wells, sensitive species/habitats/ecosystems, wetlands, surface waters, outstanding/exceptional resource waters, and significant historical/archaeological sites. There is known petroleum-impacted soil and ground water present on the site. Impacts to potential receptors will be evaluated during the Site Investigation.

4.0 SAMPLING AND ANALYSIS STRATEGY – SOIL

4.1 BORING LOCATIONS, CONSTRUCTION AND SAMPLING METHODS

Based on the presence of the UST system at the site, FISCHER proposes to advance approximately eight (8) soil borings, approximately 8-inches in diameter, to an approximate depth of ten (10) feet each. The initial soil borings will be located in the vicinity of the UST system. Additional borings will be performed radially outward from the UST system as necessary to determine the extent of petroleum-affected soil and ground water (Figure 3 - Proposed Soil Boring Locations). It should be noted that additional soil probes or borings may be required if the extent of petroleum contamination is not defined within the number of borings estimated above.

Soil samples, for field screening and chemical analysis, will be obtained continuously during the advancement of the soil borings and will be visually observed for classification, staining and other apparent petroleum signs. Each soil sample will be screened in the field for the presence of volatile vapors with a photoionization detector using headspace screening procedures.

One (1) to three (3) soil samples will be collected from each soil probe/boring. At least one (1) of those samples will be collected from above the apparent water table, in each probe/boring. The purpose of the sampling strategy is to define the horizontal and vertical extent of petroleum-impacted soil. However, analysis of soil samples collected at and below the water table can be useful in determining the extent of the ground-water contaminant plume. Sample collection and preservation procedures will be described in the Site Investigation Report and Remedial Action Plan.

Probes and borings not converted into monitoring wells will be properly abandoned in accordance with NR 141, Wisconsin Administrative Code.

Soil probes/borings will be performed on the subject property. If the field screenings, observations and laboratory analysis indicate petroleum-affected soils may have migrated off-site, FISCHER will coordinate with adjacent property owners and the WDNR. Proper authorization and permits (if necessary) for continued off-site investigation will be obtained before the investigation is continued off-site.

4.2 ANALYSIS

Soil samples will be subject to chain-of-custody procedures and will be transported to a Wisconsin certified laboratory for chemical analysis. Soil samples will be analyzed for Gasoline Range Organics (GRO), Diesel Range Organics (DRO), Polynuclear Aromatic Hydrocarbons (PAH), Petroleum Volatile Organic Compounds (PVOC), Volatile Organic Compound (VOC), Lead and geologic parameters, depending on location, in general compliance with current WDNR guidelines for petroleum-related investigations (Table 2 - Soil Sampling Parameters and Frequency). The parameters analyzed by the laboratory will be in accordance with WDNR and Environmental Protection Agency (EPA) approved methods.

4.3 QUALITY CONTROL AND ASSURANCE, DECONTAMINATION AND WASTE MANAGEMENT

There is the potential for the laboratory to detect volatile compounds in soil samples field preserved with methanol, as a result of adsorption of contaminants in the air. Therefore, as required, one (1) methanol trip blank per day will be prepared and submitted to the laboratory with the soil samples.

Soil sampling devices will either be decontaminated between samples in the field with soap solutions and water rinses or will be disposed of after each use. Augers will be steam cleaned prior to each soil boring. Clean latex gloves will be donned between samples. These methods will be implemented to eliminate cross-contamination between samples and the introduction of contaminants to the samples.

Soil cuttings appearing to be impacted, based on field observations and screening, will be placed in Department of Transportation (DOT) approved 55-gallon drums for future disposal. The drums will be properly labeled, closed and left on-site. It will be the responsibility of the consultant (FISCHER) to oversee the removal of the drums from the site for treatment and/or disposal. However, the drum(s) and contents will be left on-site in the care, custody, and control of the property owner until the drums are removed from the site under FISCHER personnel supervision.

The state certified laboratory will follow quality control and assurance procedures in accordance with WDNR and EPA protocol for the approved analytical methods utilized.

5.0 SAMPLING AND ANALYSIS STRATEGY – GROUND WATER

5.1 GROUND-WATER MONITORING WELL LOCATIONS, CONSTRUCTION AND SAMPLING METHODS

Ground-water monitoring wells will be installed at the site in approximately three (3) borings. The ground-water monitoring wells will be installed in accordance with the standards set forth in NR 141, Wisconsin Administrative Code. The ground-water monitoring well construction will generally consist of a five (5) or ten (10) foot length of 2-inch diameter Polyvinyl Chloride (PVC) 0.010-inch slotted screen, and solid schedule 40 PVC riser pipe. The ground-water wells will be constructed such that the well screen will intersect the water table to permit the detection of free-petroleum product on the water surface. A flush-mounted or aboveground protective casing will be installed over the riser.

Ground-water monitoring wells will be developed, purged and sampled. Portable pumps will be used to develop and purge the wells. Disposable bailers will be used to collect ground-water samples. Samples for metals analysis will be field filtered with disposable 45 micron filters. Sample collection and preservation procedures will be described in the Site Investigation Report and RAP.

Ground-water monitoring wells will be installed on the subject property. If the laboratory analysis indicates petroleum-affected ground water may have migrated off-site, FISCHER will coordinate with adjacent property owners and the WDNR. Proper authorization and permits (if necessary) will be obtained before the investigation is continued off-site.

5.2 ANALYSIS

Ground-water samples will be subject to chain-of-custody procedures and will be transported to a Wisconsin certified laboratory for chemical analysis. The ground-water samples will be analyzed for parameters in general compliance with current WDNR guidelines for petroleum related investigations (Table 3 – Ground-water Sampling Parameters and Frequency). The parameters analyzed by the laboratory will be in accordance with WDNR and EPA approved methods. Ground-water samples collected from the monitoring wells may be field analyzed for Dissolved Oxygen (DO), conductivity, pH, temperature, Oxygen-Reduction potential and Ferrous Iron. Ground-water samples collected from the monitoring wells will be initially analyzed for VOC and Lead and subsequent samples will be analyzed for VOC or PVOC and Lead, depending on the initial round of analytical results. Subsequent sampling events may include collection of ground-water samples to be analyzed for Natural Attenuation (NA) parameters (Sulfate, Nitrate, Alkalinity, dissolved Manganese and Methane). The parameters analyzed by the laboratory will be in accordance with WDNR and EPA approved methods.

5.3 QUALITY CONTROL AND ASSURANCE, DECONTAMINATION AND WASTE MANAGEMENT

There is the potential for the laboratory to detect volatile compounds in ground-water samples as a result of absorption of contaminants from materials encountered during shipping. Therefore, as required, one (1) trip blank per sampling event will be prepared and submitted to the laboratory with the ground-water samples.

There is the potential for the laboratory to detect volatile compounds in the samples as a result of cross-contamination. However, since FISCHER will utilize disposable sampling equipment, this potential should be eliminated.

Since poor field sampling techniques may result in analytical results that are non-reproducible, one (1) field duplicate sample per sampling event will be prepared and submitted to the laboratory with the other ground-water samples. Comparison of the analytical result for the field duplicate will give an indication of the reliability of the quantified result for the sample.

Portable pumps will be decontaminated between wells with water rinses. Sampling bailers, rope, tubing and filters will be disposed of after each use. Clean latex gloves will be donned between samples. These methods will be implemented to eliminate cross-contamination between samples and the introduction of contaminants to the samples.

Purge water will be placed in DOT approved 55-gallon drums for future disposal. The drums will be properly labeled, closed and left on-site. If analytical results indicate the absence of contaminants, the purge water will be allowed to infiltrate into the ground surface. It will be the responsibility of FISCHER to oversee the removal of the drums from the site for treatment and/or disposal. However, the drum(s) and contents will be left on-site in the care, custody, and control of the property owner until the drums are removed from the site under FISCHER personnel supervision.

The state certified laboratory will follow quality control and assurance procedures in accordance with WDNR and EPA protocol for the approved analytical methods utilized.

6.0 SCHEDULE OF EVENTS

The field investigation is anticipated to begin within approximately 15 days after the submittal of this work plan, depending upon commodity service scheduling and utility clearance. After well installation and boring, a site survey, including determination of well elevations, will be completed. A report will be written, summarizing the analytical and field results obtained during the field investigation, and submitted to the WDNR, as required.

222 West 3rd Street, Kaukauna, WI (Outagamie County)
WDNR LUST ID #03-45-1729
FISCHER Project #398132.002

Dear Mr. Tsoris:

This letter is to inform you that Fischer Environmental Consulting, LLC. (FISCHER), was retained on February 18, 1998 by Mr. John Sundelius, Street Superintendent for the City of Kaukauna, to conduct a Site Investigation at the above referenced site. The purpose of the Site Investigation will be to determine the extent of petroleum-affected soils and/or ground water, prepare and submit a Site Investigation Report and Remedial Action Plan, and to oversee the remediation of soils and/or ground water requiring remediation per Wisconsin Department of Natural Resources (WDNR) guidelines and regulations.

OMNNI Associates has been conducting a Site Investigation with regards to the waste oil underground storage tank (UST) located at the site, since contamination was discovered in December of 1993. Reportedly, OMNNI detected contamination in a ground-water sample collected from a sump located near the other USTs. FISCHER's Site Investigation will be in regards to the three (3) other USTs.

Per our telephone conversation on February 23, FISCHER will continue to use the WDNR ID number currently assigned to site. However, if two (2) separate plumes are detected during FISCHER's Site Investigation activities, a separate WDNR ID number will be obtained at that time.

Please send a copy of all future correspondences concerning this project to our office. If you have any questions or need additional information, please contact us at your earliest convenience.

Sincerely,

FISCHER ENVIRONMENTAL CONSULTING, LLC.

RE: Quarterly sampling report for the City of Kaukauna Municipal Garage, 201 W. Second Street, Kaukauna, WI (LUST ID #45-1729).

Dear Tom:

This letter details the third round of groundwater sampling at the above site.

In March 1994, OMNNI completed a subsurface investigation at the City of Kaukauna Municipal Garage. As part of the investigation, five soil borings were performed. One was converted to a groundwater monitoring well to determine the impact of the petroleum contamination on the groundwater. (See Figure 1 - Site Detail Map, attached.) The initial sampling round revealed detections of benzene, 1,2-dichloroethane, and MTBE above the DNR preventive action limits. (See Table 1 - Summary of Laboratory Analysis, Groundwater - Historical, attached.) The investigation activities are documented in a report prepared by OMNNI dated June 27, 1994.

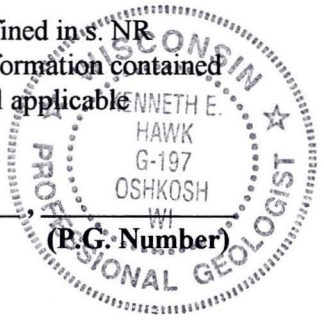
The groundwater monitoring well was sampled for the third time on September 26, 1995. All field data was recorded on a well specific field sheet. (See Well Specific Field Sheet, attached.)

The sample collected from the monitoring well was analyzed for petroleum volatile organic compounds (PVOCs) and 1,2-dichloroethane.

The laboratory analysis indicated an enforcement standard (ES) exceedance for 1,2-dichloroethane at 7.8 µg/l. (See Table 1 - Summary of Laboratory Analysis, Groundwater - Historical, and Laboratory Analysis and Chain of Custody Documentation, attached.) Benzene was not detected. The MTBE level was below the preventive action limit.

With the limited amount of historical data available, the ES exceedance in 1,2-dichloroethane is insufficient to trigger additional remedial action at ths time. OMNNI recommends the monitoring well continue to be sampled quarterly for PVOCs and 1,2-dichloroethane.

According to City officials, a spring 1996 waste oil tank removal is anticipated.



Please feel free to contact OMNNI if you have any questions regarding the City of Kaukauna Municipal Garage project.

Sincerely,

Kenneth E. Hawk
Hydrogeologist

RE: Quarterly sampling report for the City of Kaukauna Municipal Garage, 201 W. Second Street, Kaukauna, WI (LUST ID #45-1729).

Dear Tom:

This letter details the second round of groundwater sampling at the above site.

In March 1994, OMNNI completed a subsurface investigation at the City of Kaukauna Municipal Garage. As part of the investigation, five soil borings were performed. One was converted to a groundwater monitoring well to determine the impact of the petroleum contamination on the groundwater. (See Figure 1 - Site Detail Map, attached.) The initial sampling round revealed detections of benzene, 1,2-dichloroethane, and MTBE above the DNR preventive action limits. (See Table 1 - Summary of Laboratory Analysis, Groundwater - Historical, attached.) The investigation activities are documented in a report prepared by OMNNI dated June 27, 1994.

The groundwater monitoring well was sampled for the second time on January 23, 1995. All field data was recorded on a well specific field sheet. (See Well Specific Field Sheet, attached.)

The sample collected from the monitoring well was analyzed for petroleum volatile organic compounds (PVOCs) and 1,2-dichloroethane.

The laboratory analysis revealed a preventive action limit exceedance for 1,2-dichloroethane at 4.7 μg/l. (See Table 1 - Summary of Laboratory Analysis, Groundwater - Historical, and Laboratory Analysis and Chain of Custody Documentation, attached.)

The laboratory analysis during this round are consistent with the previous results for 1,2-dichloroethane. Unlike the initial round of sampling, benzene was not detected. The MTBE level was below the preventive action limit.

OMNNI recommends the monitoring well continue to be sampled quarterly for PVOCs and 1,2-dichloroethane.

According to City officials, the waste oil tank is being removed during spring/summer of 1995.

Please feel free to contact OMNNI if you have any questions regarding the City of Kaukauna Municipal Garage project.

Sincerely,

Dave Fries
Hydrogeologist

RE: Information on Site Investigation/Remediation
Waste Collection Site, Kaukauna, WI
WDNR LUST ID # 45-1729

Dear Mr. Sundelius:

On July 15, 1994, our office sent you a "Notice to Proceed" letter. In this letter, the WDNR requested that you or your consultant provide us with status reports providing an update of site activities. Since July 15, 1994, we have not received any updates concerning investigation/remediation activities at this site.

By February 13, 1995, please provide this office with an update of activities that have occurred since July 15, 1994. We request that you continue to submit status reports on a quarterly basis. You should submit correspondence and reports to:

Wisconsin Department of Natural Resources
Attn: Thomas Verstegen
905 Bayshore Drive, Box 2565
Oshkosh, WI 54903
414-424-7887

All submittals should be identified with the WDNR LUST ID number listed above.

In order to assist both you and your consultant in understanding what is required by the Department, please refer to the "Site Investigation Checklist" that was provided to you earlier; it was prepared by the Department as a summary of what needs to be done, the rules that need to be followed, and the standards which need to be met for a complete assessment and ultimate closeout of a LUST site.

Investigative groundwater and soil samples should be analyzed according to the parameters listed in the LUST Analytical Guidance publication. It is very important that your consultant understands and meets the minimum standards established by the Department.

Your failure to proceed with the investigation and remediation at this site could result in enforcement action.

SUBJECT: Acknowledgement of Receipt - Soil and Groundwater Investigation Report, Kaukauna Municipal Garage, LUST Unique ID #45-1729

Dear Mr. Sundelius:

My office received the above mentioned report on July 7, 1994. The report has not been reviewed nor approved by the Department; however, you should proceed with your consultant's recommendations.

Once the work is completed, your consultant should certify to you that the work is in compliance with the Department's standards for investigation and soil and/or groundwater cleanup. Adequate documentation in the form of formal reports, i.e. Site Investigation, Remedial Action Report, and/or Closure Report, should be submitted to the Department. The major goals of any environmental cleanup action are to define the extent of contamination, choose appropriate remedial options and remediate soils/groundwater to state standards. All applicable State of Wisconsin regulations must be followed for these projects.

Effective this date, every 90 days, you or your consultant should provide the Department with a status report providing an update of site activities. Because the Department is experiencing a backlog of emergency and high priority sites (your site is currently ranked as "Low" priority), workload and staffing levels do not allow us to provide you with review and oversight at this time. However, as workload and staff levels are adjusted, we will review your consultant's work for completeness at the time you request a PECFA review or closeout of your site. You should continue to submit correspondence to the following address:

Wisconsin Department of Natural Resources
Attn: Tom Verstegen
905 Bayshore Drive
Box 2565
Oshkosh,WI 54903

Printed on Recycled Paper

All correspondence and reports should be identified with the assigned WDNR LUST ID number. Unless otherwise requested, please send only one copy of all submittals.

If you are interested in obtaining the protection of limited liability undert s. 144.765, Stats., please contact Mark Giesfeldt at (608) 267-7562 or Darsi Foss at (608) 267-6713, in the Department of Natural Resources' Madison office for more information. The liability exemption under s. 144.765, Stats., is available to persons who meet the definition of "purchaser" in s. 144.765 (1) (c) and receive Department approval for the response actions taken at the property undergoing cleanup. The Department will determine eligibility for this program on a case-by-case basis, prior to the "purchaser" developing a scope of work for conducting a ch. NR 716 site investigation at the property.

If I can be of further assistance, please feel free to contact me at (414) 424-7887.

Sincerely,

Thomas Verstegen

EXECUTIVE SUMMARY

OMNNI has completed the subsurface investigation at the City of Kaukauna Municipal Garage, 201 W. Second Street, Kaukauna, WI. The investigation was performed at the request of the Wisconsin Department of Natural Resources (DNR) following the report of petroleum contamination discovered during maintenance of piping for an underground waste oil storage tank (UST) in December, 1993. The waste oil tank remains in use.

In order to determine the extent of the contamination, five soil borings were completed at the site on March 21, 1994. A groundwater monitoring well was constructed in one of the borings.

The soil samples collected from each boring were tested for diesel range organics (DRO) and petroleum volatile organic compounds (PVOCs). The sample collected from boring B4 was also tested for polynuclear aromatic hydrocarbons (PAHs), lead, cadmium, and PCBs. The groundwater sample was tested for DRO, lead, cadmium, and volatile organic compounds (VOCs).

Analytical test results indicated that the soil has been impacted in the tank bed area. Soil samples collected from borings located away from the tank bed indicate that the contamination is not extensive. The groundwater has not been impacted downgradient of the waste oil tank.

OMNNI recommends that a remedial action plan be developed to address the soil contamination associated with the waste oil tank system. The remedial action should occur during the tank removal. OMNNI also recommends that the monitoring well on-site be sampled quarterly for PVOCs to continue to monitor the groundwater quality at the site.

INTRODUCTION/BACKGROUND

In December, 1993, petroleum contamination was discovered during maintenance of piping for an underground storage tank containing waste oil. Laboratory analysis results indicated a diesel range organics (DRO) concentration of 1,200 ppm in a sample collected at this time. The tank remains in use. The piping maintenance work was performed by U.S. Petroleum Equipment and Environmental Services.

OMNNI was contracted by the City of Kaukauna to perform the investigation at the site. The site is located in the N 1/4 of Government Lot 22, T21N, R18E, Outagamie County, Wisconsin. (See Figure 1 - Site Location Map, Appendix A.)

Contact: Mr. Mike Greil.

Laboratory: EN CHEM Inc., 1795 Industrial Drive, Green Bay, WI 54302; (800) 736-2436.
Contact: Mr. Dave Turiff.

GEOLOGY AND HYDROGEOLOGY

Surficial deposits in the vicinity of the site consist of sediment deposited during the Wisconsin Glaciation. According to United States Geological Survey maps (Water Resources of Wisconsin - Fox-Wolf River Basin, by Perry G. Alcott, 1968), these deposits are composed of glacial lake deposits consisting of mainly silt and clay. The silt and clay overlie the undifferentiated Platteville Formation, Decorah Formation, and Galena Dolomite of Ordovician age.

Subsurface materials encountered during drilling activities consisted of silty sands (SM) and sandy clay (CL) throughout each boring. Bedrock was encountered at a depth of approximately 10.5 feet on-site. Topography on-site is generally flat. Immediately off-site it slopes more steeply upward to the west. The Fox River is located approximately 1/6 mile to the northeast of the site, and Kankapot Creek is located to the east - southeast of the site.

The local groundwater movement is expected to be east - northeast. The depth to the shallow groundwater is approximately four feet.

Variations in groundwater depth and flow direction typically occur due to seasonal variations, and underground structures (e.g., sewers).

Surface water drainage in the general vicinity of the site is controlled by an engineered storm sewer system located on Third Street.

FIELD ACTIVITIES

SOIL BORINGS

Soil boring activities were performed on March 21, 1994. A total of five soil borings were installed to identify the extent of soil contamination. (See Figure 2 - Site Detail Map, Appendix A.) A groundwater monitoring well was installed in one of the soil borings to determine the impact of the contamination on the groundwater.

The borings were installed to depths of between 8.0 and 10.0 feet. (See DNR Forms, Appendix C, for specific information on boring and well construction.) The soil borings that were not converted to groundwater monitoring wells were properly abandoned per NR 141. (See DNR Forms, Appendix C for Borehole Abandonment Forms.)

Soil samples were obtained at two-foot intervals for field screening. At each sampling interval, a representative portion of the soil was also collected for possible laboratory analysis. (See Handbook of Field Procedures, Appendix D.) Soil samples were chosen from each boring for laboratory analysis based on headspace PID screening data, the location of the water table, and visual and olfactory observations.

WELL INSTALLATION

The monitoring well was installed and developed according to NR 141 groundwater monitoring well requirements. A seven-foot screen was placed in the well at a depth of approximately 10.5 feet, to intersect the water table at the site.

OMNNI surveyed the well. Elevations are based on a local reference point. Ground elevation was surveyed to the nearest 0.1 foot, and the top of the well casing to the nearest 0.01 foot.

The groundwater monitoring well was developed on March 31, 1994 and a sample was obtained from the well on April 12, 1994. (See Well Specific Field Sheets, Appendix C). Water level readings obtained by OMNNI indicated that the depth to the shallow groundwater table is approximately four feet from the ground surface.

FIELD AND ANALYTICAL RESULTS

SOIL

Results of field headspace screening of soils showed readings of between 0.0 ppm and 1,000 ppm (isobutylene equivalents) for all soil samples screened. (See Table 1 - Summary of Field Headspace Analysis, Soil Boring Samples, Appendix B.) The sample that exhibited the 1,000 ppm headspace had an odor characteristic of solvents and not waste oil. Field screening results and field observations showed waste oil contamination in boring location B4 only. Background readings of the ambient air prior to sampling were 0.0 ppm.

All samples collected for laboratory analysis from the area surrounding the waste oil tank system were tested for DRO and PVOCs. The sample collected from boring B4, located next to the tank bed, was also tested for PAHs, lead, cadmium, and PCBs.

Results of analytical testing on soil samples collected during drilling activities showed a DNR interim soil cleanup guideline exceedance (250 ppm) for DRO in the sample collected from B4. (See Table 2 - Summary of Laboratory Analysis, Soil Boring Samples, Appendix B, and Laboratory Results and Chain of Custody Documentation, Appendix F.) The DRO concentration in the sample collected from boring B5 was 12 ppm. DRO were not detected above the method detection limit in the samples collected from B1 - B3. Some low level PVOCs were detected in three of the borings. The interim guidelines for PVOCs were not exceeded. PCBs and PAHs were not detected above their method detection limits in sample B4-3. Lead was detected at a concentration of 4.4 ppm and cadmium was detected at a level of 0.03 ppm.

GROUNDWATER

The monitoring well was sampled on April 12, 1994. The groundwater sample was analyzed for VOCs, DRO, lead and cadmium during the first round.

Laboratory analysis results showed that the groundwater on-site has been slightly impacted. (See Table 3 - Summary of Laboratory Analysis, Groundwater, Appendix B.) Several VOCs were detected in the well. Benzene, 1,2-dichloroethane, and MTBE were detected above their preventive action limits (PALs). Lead was not detected above the method detection limit. Cadmium was detected at a level of 0.1 ppb.

ANALYSIS OF DEGREE AND EXTENT OF CONTAMINATION

The investigation carried out at the City of Kaukauna Municipal Garage has identified the extent of soil and groundwater contamination on-site.

The soil contamination on-site appears to be limited to the tank bed area. The samples collected from this area during the piping maintenance activities and during the investigation contained DRO levels above the interim soil guidelines (>250 ppm). Samples collected from the other soil borings during the investigation contained DRO concentrations at or below 12 ppm.

Vertical definition of the contamination in this area was determined during the investigation. Headspace screening of samples collected from B4 at this time showed contamination to be up to eight feet deep.

The groundwater sample collected from MW1, located downgradient from the tank bed, is slightly contaminated. The source of this contamination appears to be related to the waste oil tank. A DRO concentration of 690 ppb was detected in the water sample. The solvent odor observed in the soil sample collected from MW1 at a depth of 2 - 4 feet is indicative of another possible source of contamination in the well.

Depth to groundwater at this site is approximately four feet. The groundwater flow direction is expected to be to the north-northeast towards the Fox River.

CONCLUSIONS/RECOMMENDATIONS

OMNNI recommends that a remedial action plan be developed to address the soil and groundwater contamination at the site. The underground waste oil storage tank has not been removed from the site. Remediation of contaminated soil should occur in conjunction with the tank removal if cost effective. OMNNI also recommends that a monitoring program be developed to characterize trends in groundwater quality at the site. The program should provide for quarterly sampling of the wells to determine seasonal fluctuation in water table elevation and contaminant concentration. The well should be sampled for PVOCs.

STANDARD OF CARE

The conclusions presented in this investigation were arrived at using generally accepted hydrogeologic and engineering practices. The conclusions presented herein represent our professional opinions, based on the data collected at the time of the investigation, at the specific boring and sampling locations discussed in this report. Conditions at other locations on the property may be different than described in this investigation. Other than this, no warranty is expressed, implied or intended. The scope of this report is limited to the specific project and location described herein.

PERSONNEL QUALIFICATIONS

Kurt F. Zacharias - Completed 40-hour hazardous waste training.
Bachelors Degree in Natural Science from the St. Norbert College DePere, WI.
Masters Degree in Geology from Michigan State University, East Lansing, MI.
Certified Site Assessor-05254.

Faye De Broux Ewald - Completed 40-hour hazardous waste training.
Bachelors Degree in Geology and Education from University Wisconsin-Oshkosh.
Certified Hydrogeologist according to NR 500.03 (64) and NR 500.31 (e)2.
Certified Site Assessor-03689.

David L. Fries - Completed 40-hour hazardous waste training.
Bachelors Degree in Geology from Lawrence University, Appleton, WI.
Masters Degree in Environmental Science from University of Wisconsin-Green Bay.
Certified Hydrogeologist according to NR 500.03 (64) and NR 500.31 (e)2.
Certified Site Assessor-01662.

Susan M. Courter - Completed 40-hour hazardous waste training.
Bachelors Degree in Environmental Geology from University Wisconsin-Oshkosh.
Certified Hydrogeologist according to NR 500.03 (64) and NR 500.31 (e)2.
Certified Site Assessor-01661.

Jim Riggs - Completed 40-hour hazardous waste training.
Associate Degree in Natural Resource Technology from Fox Valley Technical College.

Karl Breuer - Bachelors Degrees in Earth Science and Environmental Science, University of Wisconsin - Green Bay.
Certified Hydrogeologist according to NR 500.03 (64) and NR 500.31 (e)2.

Deanna Drum - Associate Degree in Mechanical Design, Fox Valley Technical College

BORING INSTALLATION PROCEDURES

A number of different drilling firms are used for environmental investigations. Borings intended to be converted to monitoring wells are advanced using 7 5/8" O.D. x 4 1/2" I.D. hollow stem augers or 4" O.D. solid stem augers powered by a truck-mounted drill rig. If bedrock drilling is required, borings are advanced using either air or mud-rotary drilling techniques. Soil borings not intended for monitoring wells are typically advanced using 4" O.D. solid stem augers. Soil borings that are not converted to groundwater monitoring wells are properly abandoned per NR 141.

Samples are typically obtained from each boring at 2.5' intervals by split-spoon sampling according to ASTM D-1586. A portion of each sample is screened with a photoionization detector (PID). At each sampling interval, a representative portion of the soil is also collected for possible laboratory analysis. Soil samples are chosen from each boring for laboratory analysis based on headspace screening data, and visual and olfactory observations. In general, the sample from each boring that exhibits the highest PID reading is chosen for analysis. See the Soil Sampling Procedures below, for further information pertaining to field headspace analysis and sample collection procedures.

SOIL SAMPLING PROCEDURES

All soil sampling is performed in accordance with DNR PUBL-SW-127, Soil Sampling Requirements for LUST Site Investigations and Excavations and DILHR ch. 10, Flammable and Combustible Liquids. The soil samples were collected and analyzed in accordance with DNR PUBL-SW-130 92REV, LUST Analytical Guidance, July, 1993. Our standard instruments and sample collection procedures are as follows.

1. Soil samples are collected from a split-spoon sampler during environmental drilling.

2. Sample collector wears new latex exam gloves when collecting samples to decrease the risk of personal exposure and cross contamination.

3. A portion of the sample is placed in a new glass jar with a teflon lined lid, immediately placed on ice, and later delivered to the laboratory for analysis. This procedure will be discussed in more detail later in this report. (See Table 1)

4. The remaining portion of the sample is placed in a clean 4 oz. jar (approx ½ filled), and sealed with aluminum foil and a teflon lined lid. The head space sample is then agitated for minimum of 30 seconds and then allowed to equilibrate. Minimum equilibration time will correspond to the following specifications.

Ambient Outside Air Temperature at the Time of Sample Collection	Minimum Amount of Time Sample Must Equilibrate at 70 o F or Greater Temperature
< 40°F	40 min.
41 - 55°F	20 min.
56 - 69°F	10 min.
> 70°F	5 min.

When the sample has completed equilibration, it will be promptly field analyzed with a portable photoionization detector (PID). OMNNI uses either a Photovac Inc. Microtip HL-200 or a Thermo Environmental Instruments Model 580A OVM, both equipped with a 10.6 ev lamp. A background reading is first taken. The PID probe is then inserted into the jar through a single hole in the aluminum foil. The instrument reading is measured at one-half the distance between the foil seal and the sample surface. The measured reading is then recorded.

Isobutylene at a concentration of 100 ppm is used for field calibration gas. The PID meter is field calibrated at the following times:

- At the beginning of each day
- After any significant change in temperature or humidity
- Every 3 hours
- After any repairs to the instrument are performed

5. All samples are returned to the laboratory as soon as possible, usually the day the sample was collected. All samples are returned to the lab with a chain of custody form, form #4400-151. Time of sample collection and sample PID reading is listed. Care is taken to ensure that the chain-of-custody form is properly and fully completed before submitting to the laboratory.

6. The samples will be sent to a laboratory certified by the Wisconsin Department of Natural Resources.

7. Table 2 on page 9 outlines the required DNR laboratory analysis for specific UST contaminants.

Soil analyses, other than those in Table 2 will be conducted in accordance with methods approved by the DNR.

MONITORING WELL INSTALLATION AND DEVELOPMENT PROCEDURES

The monitoring wells are typically constructed of two-inch, schedule 40, flush-threaded PVC casings and well screens. Prior to use, well parts are individually wrapped in plastic.

Wells are installed and developed according to NR 141, DNR Groundwater Monitoring Well Requirements. The monitoring wells are installed with ten or fifteen foot screens which are placed in the borings to intersect the water table. Piezometers are installed with five foot screens sealed beneath

the water table. Filter pack and annular space seal material are installed by gravity as the augers are withdrawn from the hole. Wells are cut to the required height using a PVC pipe cutter.

An as-constructed well and boring survey is performed by OMNNI once field work is complete. Elevations are either based on a local datum of 100 feet, or a U.S.G.S. elevation, assigned to a mark on a reference point located at the site. Ground elevation is surveyed to the nearest 0.1 foot, and the top of the well casing to the nearest 0.01 foot.

A horizontal grid system is established at the site with the origin of the grid set on the reference point. Wells and borings are located with respect to this grid system.

To properly develop each monitoring well, water is removed until a consistent water quality is obtained. This is done by removing 10 times the water volume in the well and filter pack, removing water until it is free of sediment, or removing the water until the well is purged dry. Water is removed from the wells by bailing the water with as little agitation as possible. If the water level is unaffected by bailing and large amounts of water are to be removed, the well is developed by using the surge and purge method with a Red Lion centrifugal pump. No water is added to the well during development.

The development water is barrelled, pending the results of analytical testing. If the well is suspected to be clean and small volumes of water are to be removed, the water may be spread on pavement to volatilize any possible contaminants.

GROUNDWATER SAMPLING PROCEDURES & V.O.C. SAMPLING NOTES

A. Devices used to measure water elevation, purge wells and retrieve samples:

1. Groundwater levels are measured with a fiberglass reel tape with a weighted stainless steel "sounder" at the end.

2. In wells that have free product on top of the water surface, depth to water and depth to product are measured with a fiberglass reel tape with an interface probe at the end.

3. Wells are purged and samples are collected by one of the following methods:

   a) Wells are purged with a Voss disposable bailer.

   b) Alternate purging and sampling equipment consists of Fultz centrifugal groundwater sampling pump.

B. Procedures for calculating purge volumes, purging wells and sampling:

1. Wells are normally sampled starting from the up-gradient area and progressing toward the down-gradient area of the site. When the degree of contamination is known, least contaminated wells are sampled first, the more contaminated wells sampled last.

2. All the wells are opened before the depth to groundwater is determined.

3. Wells are purged by removing four water volumes within a casing or all the water until the well runs dry.

4. Once all the wells have been purged, the samples are drawn using equipment mentioned above.

5. Sample, odor, turbidity, temperature, conductivity and pH are determined on the unfiltered portion of the sample and recorded on the well specific field sheet. A Hydac pH / Temperature / Conductivity meter is used for in field measurements.

6. When the sample requires filtering, the sample is filtered with an in-line pump (as soon after collection as possible).

7. Quality Assurance / Quality Control Samples

   a) Trip and field blanks will consist of three new 40 ml vials filled with deionized water. These are sent to the laboratory for (P)VOC analysis. If no field contamination has occurred, these samples will have no detectable (P)VOCs.

   b) One trip blank should be analyzed for every 10 samples collected. Trip blanks are poured, labeled, and sealed, then taken out in the field. Trip blanks are kept with all samples collected until reaching the field.

   c) Field blanks are used if the bailers are not dedicated to a specific well. If there is a possibility for field cross contamination of samples, field blanks may also be taken at the sample collectors discretion.

   d) One temperature blank is collected per batch of samples.

   e) One duplicate sample is collected with every 10 samples.

8. Samples are refrigerated, then transported to a State certified laboratory for testing as soon as possible.

9. A chain of custody will be filled out listing all samples collected, requested laboratory analysis, date and time of collection, and the name of the sample collector. This document will remain with the samples at all times and bear the names of all persons handling the samples until the samples are received by the laboratory.

C. Procedures for cleaning equipment:

1. In the field, sampling equipment is rinsed with a 10% methanol solution and then flushed three times with deionized water between each well sampled.

2. Equipment that is still contaminated after field cleaning will be rinsed with tap water, washed off with detergent, rinsed with a 10% methanol solution, and flushed three times with deionized water.

D. Transporting samples to lab:

1. Filtered, preserved, labelled, and sealed samples are iced and transported to the lab for analysis as soon as possible.

2. The laboratory will be notified by the sample collector when courier service is required.

E. The above procedures constitute normal groundwater sampling procedures. Modifications to each of the outlined items may be applicable for site specific conditions or special volatile organic sampling considerations. Methods used are consistent with WDNR "Groundwater Sampling Procedures Guidelines" Publ. WR-153, February, 1987.

DECONTAMINATION PROCEDURES

Decontamination is the process of removing and/or neutralizing contaminants that may have accumulated on PPE (personnel protective equipment) and equipment. Proper decontamination is a critical element in the control of hazards which helps ensure the health and safety of workers. Proper decontamination also contains the contamination to the site, thus preventing further environmental problems.

The following decontamination procedures should be used when completing borings, installing monitoring wells, and/or installing remediation systems.

A. Between samples, the split spoon will be cleaned in a multiple rinse, surfactant solution (soap and water or Alconox solution).

B. The sample will be collected while wearing new latex exam gloves.

C. The surface upon which the sample is collected will be cleaned between samples.

D. If sample collector(s) is wearing gloves, they will be changed between samples.

E. Soil which has accumulated around the boring will either be stockpiled or barreled. If the soil is stockpiled, it will be placed on and covered with visqueen. The stockpiled or barreled soil will later be disposed of in compliance with the DNR regulations.

F. Upon completion of the boring, the augers will be decontaminated before they are used again. The following procedures will be followed when decontaminating drilling equipment:

1. A decontamination basin lined with plastic (visqueen) is set up near the work area.

2. All contaminated equipment is placed in the decontamination basin.

3. A pressurized steam cleaner is used to clean all contaminated equipment.

4. Following steam cleaning, the auger is removed from the decontamination basin.

5. Upon completion of the job, the accumulated water in the decontamination basin is pumped out and placed in a barrel. Wash water used for cleaning the split spoons is also added to the barrel. The barrel will be disposed of in compliance with all regulatory agencies.

6. The visqueen used in the decontamination basin is disposed of in compliance with all regulatory agencies.

WDNR OSH
LUST PROGRAM

Wisconsin Department of Natural Resources
Attn: Mr. Thomas Verstegen
905 Bayshore Drive
Box 2565
Oshkosh, WI 54903

RE: City of Kaukauna, 201 W. Second Street, Kaukauna, WI;
DNR LUST ID #45-1729

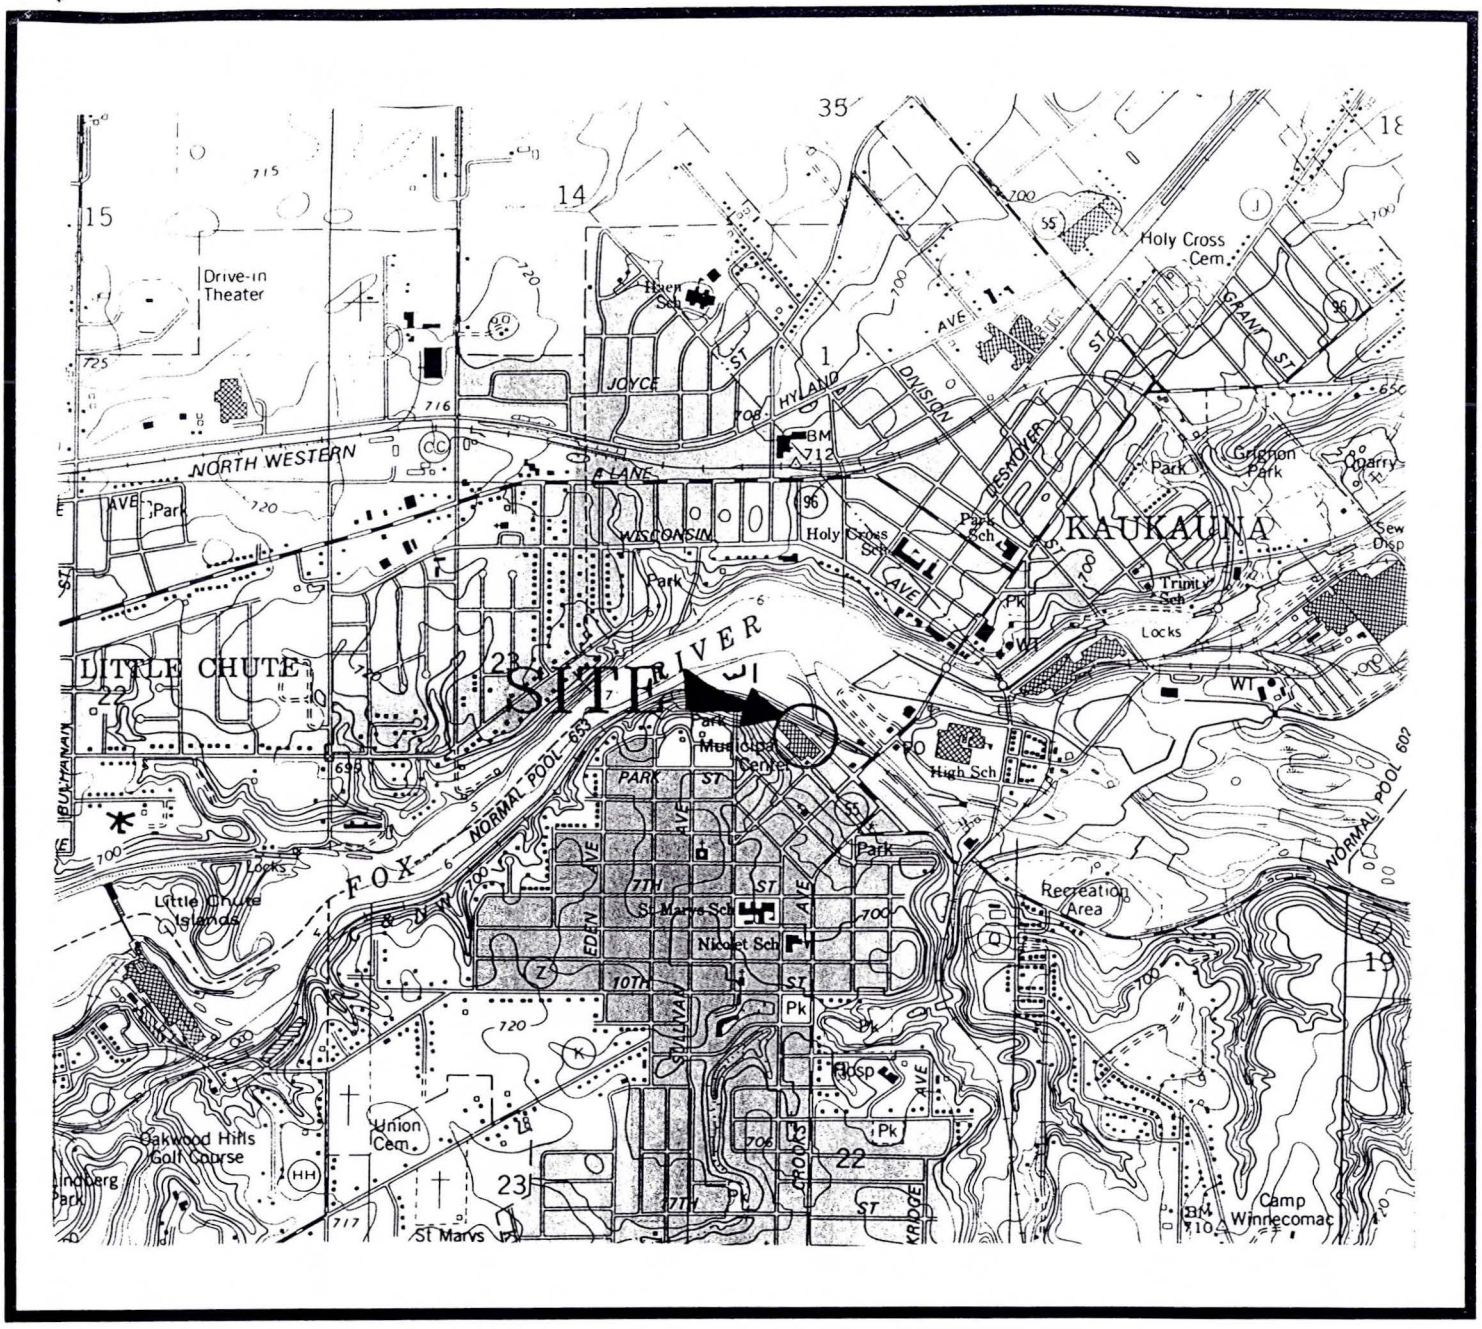
Dear Mr. Verstegen:

OMNNI has been contracted by the City of Kaukauna to perform a site investigation of subsurface conditions at the above mentioned location. (See Figure 1 - Site Location Map, enclosed.)

In December, 1993, petroleum contamination was discovered during maintenance of piping for an underground waste oil storage tank. (See Figure 2 - Site Detail Map, enclosed.) Laboratory analysis results indicated a diesel range organics (DRO) concentration of 1,200 ppm in a sample collected at this time. The waste oil tank remains in use.

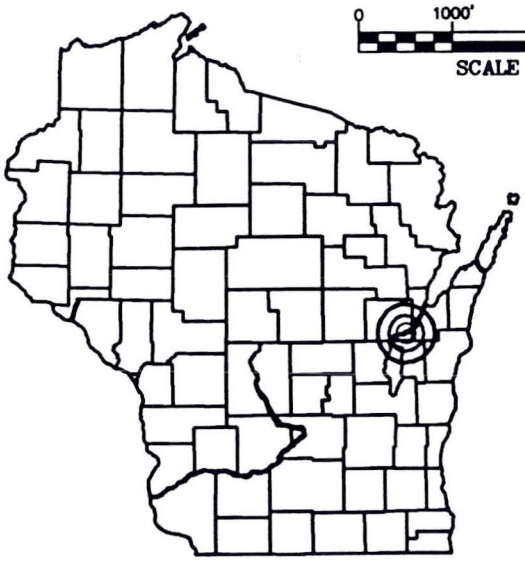
As the next step in investigation of the site, OMNNI proposes to install three - five soil borings on the property with continuous sampling by field screening with a PID. Soil samples will also be collected and delivered to a certified analytical laboratory for analysis. Sampling parameters will be chosen in order to comply with leaking underground storage tank (LUST) analytical guidelines (DNR, July, 1993).

Groundwater monitoring wells will be constructed and developed per NR 141 in three of the borings. After development, groundwater sampling from the wells will be performed. Again, groundwater sampling parameters will be chosen in order to comply with leaking underground storage tank guidelines. (See Figure 2 - Site Detail Map, for proposed boring and monitoring well locations.)



If you have any questions concerning this phase of work for the above mentioned site, please feel free to contact OMNNI. OMNNI is currently bidding the commodity services and has scheduled the work for the week of March 28, 1994. If we have not heard from you before our tentative schedule, we will assume that the work plan meets with your approval.

Sincerely,



David Fries
Hydrogeologist

Mr. Tom Verstegen
Wisconsin Department of Natural Resources
905 Bayshore Drive, P.O. Box 2565
Oshkosh, WI 54903-2565

Subject: **City of Kaukauna Municipal Services Building**
Kaukauna, Wisconsin

Dear Mr. Verstegen:

Subsurface petroleum contamination was encountered during maintenance of piping associated with an underground waste oil storage tank on December 28, 1993 at the subject site. A soil sample was collected and found to have a DRO concentration of 1,200 mg/kg. A copy of the analytic test report is included with this letter.

Copies of the analytic test report has also been sent to four consulting firms for preparation of proposals to conduct the required remedial investigation\remedial action planning (RI/RAP). As required by ILHR 47, the City of Kaukauna will review the proposals and select a consultant to perform the RI/RAP. We expect the proposals from the consultants to be received by the end of January 1994. A consultant should be selected in February 1994 and will submit their investigation workplan to you for review. The field work can potentially be initiated in March 1994.

Please contact me or the City of Kaukauna Street Superintendent (Mr. John Sundelius) if you have any objections to our proposed schedule. If you have any questions or comments, or require additional information regarding this project, please call me at (414) 735-8234.

Sincerely,
U.S. Petroleum Equipment

SUBJECT: Notification of Petroleum Contamination from Underground Storage Tank System
Kaukauna Waste Oil Collection Site, 200 Block of 3rd Street, Kaukauna
WDNR LUST ID #45-1729

Dear Mr. Sundelius:

On December 28, 1993, Jesse Rose of U.S. Oil notified the Wisconsin Department of Natural Resources (WDNR) that petroleum contamination was discovered at the above referenced location. The purpose of this letter is to inform you of your legal responsibilities to address this situation.

Releases from underground storage tanks regulated under Subtitle I of the Resource Conservation and Recovery Act require compliance with the provisions of 40 CFR, Parts 280 and 281. The Environmental Protection Agency (EPA) has the authority to take enforcement action at any time, but will generally not take actions against parties cooperating with the state. The WDNR proceeds in LUST cases under the authority of s. 144.76, Wisconsin Statutes, commonly referred to as Wisconsin's Hazardous Substance Spill Law. The definition of "hazardous substance" as found in s. 144.01(4m), Stats., includes petroleum products.

> Wisconsin Statute 144.76(2a) states: "A person who possesses or controls a hazardous substance or who causes the discharge of a hazardous substance shall notify the Department immediately of any discharge not exempt under sub. (9)."
>
> Wisconsin Statute 144.76(3) states: "A person who possesses or controls a hazardous substance which is discharged or who causes the discharge of a hazardous substance shall take the actions necessary to restore the environment to the extent practicable and minimize the harmful effects from the discharge to the air, lands, or waters of the state."

Because you possess or control a hazardous substance that has been released to the environment, the Department identifies you as the party responsible for taking the actions necessary to restore the environment. The conditions present at this site pose a potential threat to human health and/or the environment. You are required to immediately identify any risks or explosive vapors and/or well contamination. You are required to conduct an investigation to determine the extent of contamination, the potential for groundwater impacts, and the remedial action(s) necessary to clean up contaminated soil and groundwater. You must dispose of or treat all products, soils, wastewater, or sludges in compliance

with all applicable federal, state, and local laws and regulations. All groundwater remediation projects which discharge to surface or groundwater (including all discharges to storm sewers) must be covered by a WPDES Discharge Permit. The only discharges not requiring a permit are those to a sanitary sewer; however, in those cases, the treatment facility receiving the discharge and the owner of the sewer system must be contacted for approval. An application must be submitted as early as possible to allow time for needed monitoring or additional data collection prior to discharge. The permit will contain discharge limits for pollutants of concern, along with sampling frequency and test methods.

Before any contaminated soil can be treated or disposed, an "Application to Treat or Dispose of Petroleum Contaminated Soil" must be completed and approved by the DNR's Air Management staff. Until the contaminated soils can be treated or disposed of, they should be stored on an impermeable surface, bermed to prevent runoff and runon, and covered with an impermeable cover material such as plastic.

By February 15, 1994, you must hire an environmental consultant and have them submit written verification to this Department that they have been hired to investigate the extent of the contamination problem and oversee remediation at this site. By March 15, 1994, your consultant must submit a site investigation workplan.

Due to current workload and staffing levels, a WDNR project manager has not been assigned to this case; however, investigation and remediation must not be delayed pending WDNR review or approval of workplans. Correspondence and reports should be sent to the Department at the following address:

Wisconsin Department of Natural Resources
Attn: Thomas Verstegen
905 Bayshore Drive, Box 2565
Oshkosh, WI 54903
Phone: 414-424-7887

All correspondence and reports submitted by you or your consultant should be identified with the assigned WDNR LUST ID number. Unless otherwise requested, please send only one copy of all submittals. Please share this information with the consultant that you hire.

You are encouraged to contact the Department of Industry, Labor & Human Relations (DILHR), the state agency that administers the Petroleum Environmental Cleanup Fund (PECFA). This fund may reimburse you for eligible costs associated with the remedial investigation and cleanup. Linda Baldridge of DILHR should be contacted at (608) 266-2424 to obtain current information regarding the PECFA program.

Your cooperation in this matter will be appreciated. Failure to comply with these requirements could subject you to further enforcement action.

Sincerely,

Janis DeBrock

Subject: Liability Clarification and Current Environmental Conditions at the Round House Manor Property, 300 Bicentennial Court, City of Kaukauna, Outagamie County, WI, BRRTS #07-45-559282, Parcel #323-0406-00

Dear Mr. Washington:

Purpose

The purpose of this letter is to provide you with clarifications as to environmental liabilities and current environmental conditions at the property located at 300 Bicentennial Court, Outagamie Tax Parcel #323-0406-00, City of Kaukauna, Wisconsin ("the Property") The Property consists of approximately two acres in the NE1/4, NW1/4, Sec. 22, T21N, R18E, Outagamie County. Please refer to the attached Figure 1 for a map of the Property.

Summary Determination

Total Petroleum Hydrocarbons-Diesel Range Organics (TPH-DRO), metals, Volatile Organic Compounds (VOCs), and Polynuclear Aromatic Hydrocarbons (PAHs) were detected in soil and groundwater samples obtained from borings and temporary monitoring wells installed as part of a recent Limited Phase II Environmental Site Assessment; however the Department of Natural Resources ("Department") will not require additional investigation at this time and the case will be tracked as "No Action Required" ("NAR").

Request

On September 5, 2012, your consultant, Thomas Culp of SCS BT Squared requested on your behalf, that the Department issue a liability clarification letter. The letter is to contain a determination whether further response actions are needed under the ch. NR 700 rule series, Wis. Adm. Code (WAC), based on the release or presence of one or more hazardous substances at the Property. The Department received the fee for providing assistance, in accordance with s. NR 749.04(1), WAC.

In order for the Department to make this determination, you have requested a review of the following documents:

- Results of Additional Sampling, collected by SCS BT Squared, dated November 28, 2012
- "Limited Phase II Environmental Site Assessment, Property Located at 300 Bicentennial Court, Kaukauna, Wisconsin" ("Draft Phase 2 Report") containing analytical results for groundwater, soil and a site topographic map, prepared by D3G, dated January 12, 2012
- Unsigned "Phase I Environmental Site Assessment, Property Located at 300 Bicentennial Court, Kaukauna, Wisconsin" (Unsigned "Draft Phase 1 Report") containing legal descriptions and maps, prepared by D3G, dated August 4, 2011

- An application for "Technical Assistance and Environmental Liability Clarification", dated August 14, 2012 and the associated $500 review fee submitted by SCS BT Squared on your behalf

The Department has examined the reports listed above and provides the following summary of the facts of the case and opinions concerning environmental conditions at the Property.

Background and Summary of Environmental Conditions

The Round House Manor at 300 Bicentennial Court consists of a two-story age-restricted apartment structure and a one-story garage building both constructed in 1985. Prior to 1885, the Property held a railroad roundhouse, turn table, sand house, railroad water tank, portion of a coal shed, hoist, and coal dump, and railroad spurs. The former roundhouse, associated structures, and railroad spurs were demolished between 1973 and 1979.

D3G reported in the 2012 Limited Phase II Environmental Site Assessment (ESA) Report that a 2011 Phase I Assessment prepared by D3G identified a Recognized Environmental Condition (REC) at the Property. The REC appears to be related to suspected hazardous material usage associated with a former railroad roundhouse. The purposes of the Phase II ESA were to evaluate soil and groundwater quality at the site.

As part of the ESA, Four soil borings were advanced on the Property to depths of 10 to 16½ feet. Borings SB-3 and SB-4 were converted to temporary monitoring wells. Samples of soil from borings SB-1 to SB-4 and groundwater from temporary monitoring wells SB-3 and SB-4 were collected and analyzed at a state certified laboratory for TPH-DROs, Metals, VOCs, and PAHs (See Figure 1 for a map showing the locations of the borings).

SOIL

Soils at the Property are described to consist mostly of mixed layers of tightly packed fine to coarse grained sand, dense silty clay, weathered fractioned bedrock and fat clay with a mixture of rock fragments and pebbles down to 16½ feet.

Several TPH-DROs were detected in the soil samples collected from borings SB-1 to SB-4 but they did not exceed their respective allowable Residual Contaminant Level (RCL) as specified in ch. NR 720 WAC, except for borings SB-2 and SB-3. Borings SB-2 and SB-3 were completed in an area covered by concrete pavement.

Several metals were detected in the soil samples collected from borings SB-1 to SB-4. Concentrations of arsenic at borings SB-1 to SB-4 were above the respective RCL. Concentrations of lead at borings SB-1 and SB-3 were above the respective RCL. Borings SB-1 and SB-4 were located in an area covered by vegetation and borings SB-2 and SB-3 were in an area covered by concrete pavement.

Several VOCs were detected in the soil samples collected from boring SB-4 but they did not exceed their respective RCLs (See Table 1 for a summary of soil analytical results).

GROUNDWATER

Groundwater at the site was encountered from between approximately 10 ½ to 12 ½ feet below ground surface.

Several PAHs were detected in groundwater samples collected from temporary monitoring well SB-3. Concentrations of benzo[a]anthracene, benzo[a]pyrene, and phenanthrene at well SB-3 were above the ch NR 140 WAC Preventive Action Limit (PAL). Therefore on September 25, 2012, the Department requested the collection and analysis of a groundwater sample from a monitoring well, constructed according to the requirements of ch. 141 WAC, near temporary monitoring well SB-3. Elevated detections of contaminants are often seen in groundwater from temporary wells because the well screens are not properly developed and the water sample is often not an accurate representation of actual groundwater quality.

Upon discussion with the Department, SCS BT Squared installed monitoring well MW-1 according to ch. NR 141 WAC requirements and on November 8, 2012, collected a groundwater sample (Monitoring well MW-1) at a depth of 14 feet. Laboratory analysis revealed that lead was not detected at monitoring well MW-1. Several trace PAHs were detected in the groundwater sample collected from monitoring well MW-1 however they did not exceed their PALs (See Table 1 for a summary of groundwater analytical results).

After receipt and review of the above analytical results on December 4, 2012, the Department requested that monitoring well MW-1 be abandoned in accordance with ch. NR 141 WAC. Documentation that the monitoring well was properly abandoned was received on December 13, 2012.

Liability Determination

The Wisconsin Hazardous Substance Discharge Law, s. 292.11, Wis. Stats., commonly called the Spill Law, requires those who cause, possess or control a hazardous substance discharge to "take the actions necessary to restore the environment to the extent practicable and minimize the harmful effects from the discharge to the air, lands or waters of this state." Section 292.55, Wis. Stats., authorizes the Department to issue clarification letters concerning liability for environmental pollution.

Soil samples taken from borings SB-1 to SB-4 detected TPH-DROs, metals, and VOCs but there were no exceedances of ch. NR 720 RCLs, except for the concentrations of TPH-DROs at SB-2 and SB-3, arsenic at SB-1 to SB-4, and lead at SB-1 and SB-3. Borings SB-1 and SB-4 are in an area covered by vegetation and borings SB-2 and SB-3 are in an area covered by concrete pavement and therefore direct contact with the contaminated soil is limited.

In addition, several PAHs were detected in groundwater taken from temporary monitoring well SB-3. A follow-up sample collected from a monitoring well near SB-3 showed no detect for lead and PAH concentrations did not exceed the PAL.

The impacts to soil and groundwater at the property are likely related to the historic railroad activities at the Property. Based on the likely usage of petroleum based materials at the railroad roundhouse, the continued presence of trace contaminants could be expected.

Based on these conditions the Department has made a "No Action Required" determination for this case. This decision is based solely on information available and reviewed by the Department and makes no determination concerning the presence of hazardous substance in other areas of the property.

In the future, if the Department becomes aware of new information concerning the contaminants referenced above, or the presence of other contaminants on the Property not previously identified, the Department will need to evaluate that data to determine if response actions may be required.

Whenever possible, the Department requires the person who caused the discharge to take the appropriate response actions.

The Bureau for Remediation and Redevelopment Tracking System (BRRTS) identification number for this activity is shown at the top of this letter. The Department tracks information on all determinations such as this in a Department database that is available on the Internet at.http://dnr.wi.gov/botw/SetUpBasicSearchForm.do

Since there is no action required for this case, the Department has issued BRRTS case number 07-45-559282 and will track this site activity as a "No Action Required" determination. If you have any questions, please contact me at 920-662-5105, or in writing to the address at the top of this letter, or by email to kimberly.vickman@wisconsin.gov.

Sincerely,

Kimberly Vickman

Some of the statutory provisions described in this document contain legally binding requirements. However, this document does not substitute for those provisions or regulations, nor is it a regulation itself. Thus, it cannot impose legally-binding requirements on EPA, states, or the regulated community, and may not apply to a particular situation based upon the circumstances. Any decisions regarding a particular remedy selection will be made based on the statute and regulations, and EPA decision makers retain the discretion to adopt approaches on a case-by-case basis that differ from this guidance where appropriate.

Interested parties are free to raise questions and objections about the substance of this guidance and the appropriateness of the application of this guidance to a particular situation, and the Agency welcomes public input on this document at any time. EPA may change this guidance in the future.

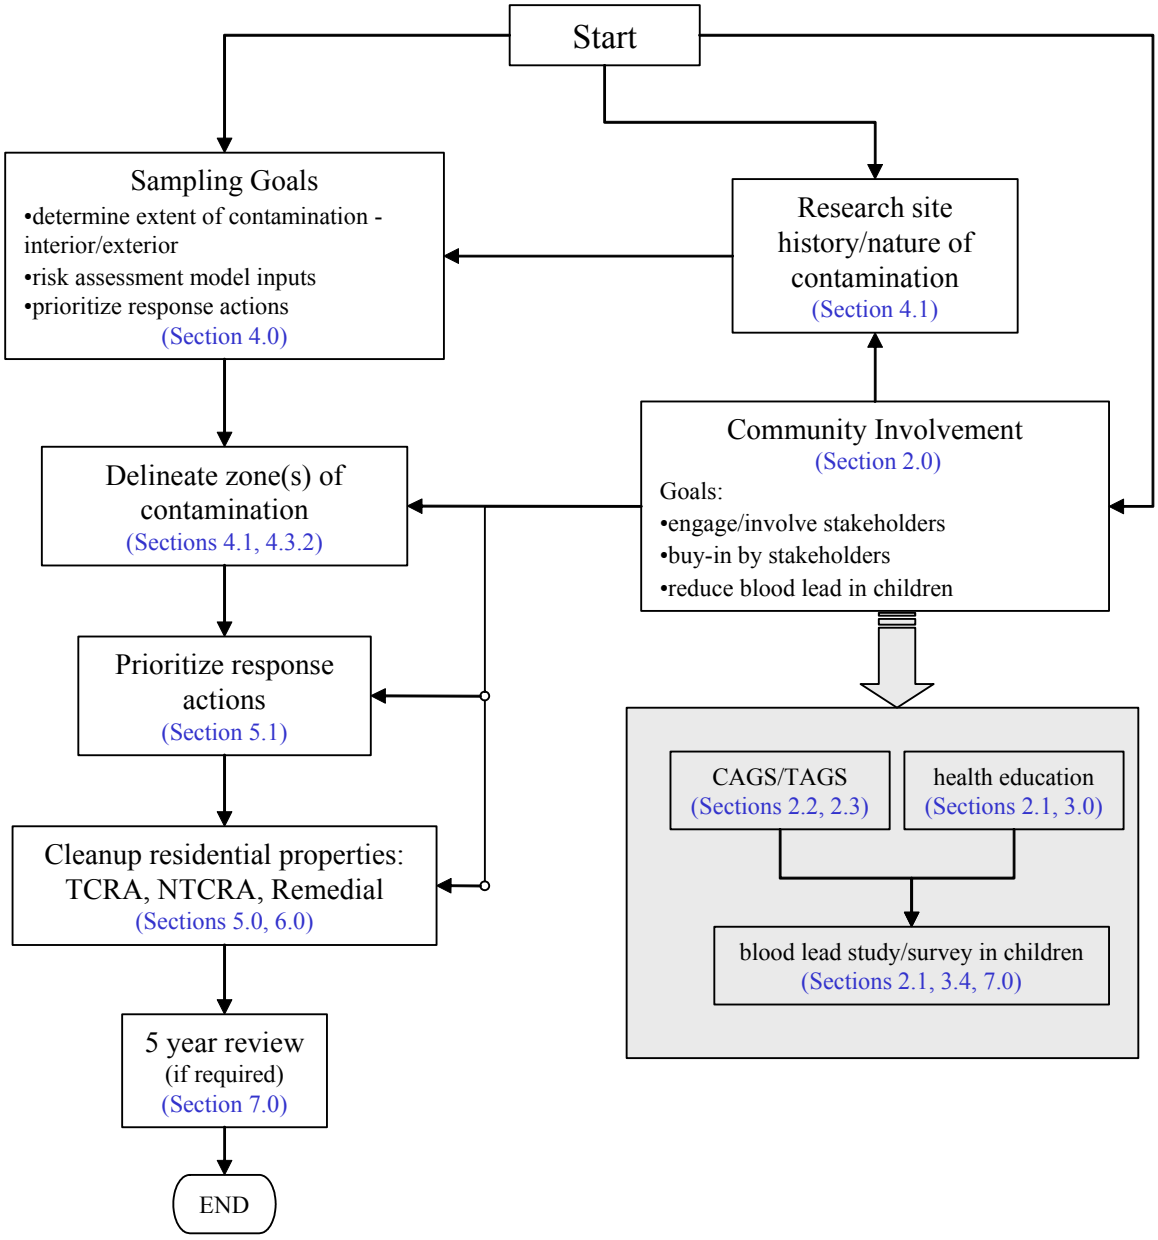
1.0 INTRODUCTION

This Superfund Lead-Contaminated Residential Sites Handbook (subsequently called the Handbook) has been developed by the U.S. Environmental Protection Agency (EPA) to promote a nationally consistent decision-making process for assessing and managing risks associated with lead-contaminated residential sites across the country.

The primary audience for this risk management document is Superfund project managers working on the characterization and cleanup of lead-contaminated residential sites; however, Resource Conservation and Recovery Act (RCRA) project managers may also find it useful. This information was developed primarily for EPA staff, but may prove useful to others working on lead-contaminated residential sites, including states, other federal agencies, tribes, local governments, public interest groups, and private industry. While this Handbook is not intended to apply to lead-contaminated commercial or industrial properties, other non-residential areas, or sites with ecological risks, some of the concepts may be useful for such properties. Addressing lead-contaminated properties at federal facilities requires a different approach, and this Handbook provides a special section (Section 8) on addressing this universe of sites.

Generally, Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) response actions are undertaken to address a release or threat of release of a hazardous substance such as lead into the environment. Lead contamination found inside homes may be caused by deteriorating lead-based paint (LBP), plumbing, or other sources not resulting from a release into the environment, and therefore may be more appropriately addressed by authorities and programs other than CERCLA (see Appendix A and Section 6.6 of this Handbook). However, it may be appropriate to use CERCLA authorities to conduct sampling and site characterization activities to determine the source of the lead contamination and to differentiate between various site-related sources.



The Handbook lays out only the minimum considerations for addressing lead-contaminated residential sites and encourages users to refer to appropriate agency guidance and/or policy to conduct more stringent investigation and clean-up activities on a site-specific basis, if necessary. In addition, the site manager should determine the applicable and relevant or appropriate requirements (ARARs), including state laws and regulations, that apply to the site. It should also be noted that this Handbook does not, outside the federal facilities universe, apply to lead-contaminated residential sites addressed under Title X (HUD, 1992) procedures.

Lead site characterization and clean-up procedures are unique owing to the ubiquitous nature of lead exposures and the reliance on blood lead concentrations to describe lead exposure and toxicity. Lead

risks are characterized by predicting blood lead levels with computer models and guidance developed by EPA, which are available on the internet: http://www.epa.gov/superfund/programs/lead/products.htm. Major improvements in the removal of lead from gasoline, paint, and food packaging have significantly reduced the incidence of severe lead poisoning. The results of this progress mean that most environmental sources of lead exposure are more likely to cause subtle adverse health effects, primarily behavioral and learning impairments.

An overview to the clean-up process is provided as Figure 1-1. Section numbers are provided in the figure to help the reader locate information within this document.

Figure 1-1. An Overview to the Clean-up Process

1.1 BACKGROUND

Elevated blood lead concentrations in young children in the United States are still prevalent in many areas. Major sources of lead contamination historically included mining and milling sites, primary and secondary smelters, battery manufacturing and recycling facilities, pesticide formulators, pesticide use in orchards, and paint manufacturers (prior to 1978). Many of the source facilities are located near residential areas or have had residential areas develop around them. Fugitive emissions from the facilities have resulted in soil contamination in the yards of residences, which in turn can cause high blood lead levels in children.

Although numerous sites of this type exist, EPA has remediated, or overseen the remediation of, many of these sites and surrounding residences. Many different clean-up methods have been implemented with varying degrees of success. This document is based on the lessons learned from EPA's experience in remediating residential lead sites. It is intended to promote consistency in the characterization and cleanup of lead-contaminated residential sites, while retaining the flexibility needed to respond to different sites and communities to ensure success of the remedy and provide long-term protection of human health. The document also provides guidance on addressing lead sources and media that the Superfund does not usually remediate, such as LBP and lead plumbing. It is anticipated that this information will be periodically updated as we strive to improve our ability to respond to environmental lead hazards.

1.2 GENERAL DISCUSSION ON CERCLA'S APPLICABILITY TO LEAD SITES

This section provides a general discussion of the sections of CERCLA that address lead-contaminated sites. A description of Title X and EPA's Toxic Substances Control Act (TSCA) IV Lead Program is provided in Appendix A. The Title X discussion is provided for informational purposes and is primarily applicable to federal facilities. Section 4.2.5 also provides useful information for LBP and dust sampling.

1.2.1 Background

Historically, the CERCLA has been used as a tool to implement clean-up activities at a large number of sites across the country. CERCLA authorities have been used for cleanups ranging from the removal of drums of hazardous substances from long-abandoned sites, to major privately funded remedial actions at sites on the National Priorities List (NPL).

CERCLA may apply any time there is a release or threatened release of: (1) a hazardous substance into the environment, or (2) a pollutant or contaminant "which may present an imminent and substantial endangerment to the public health or welfare" (EPA, 2000a). The term "release" is defined broadly in the statute and includes discharging or leaking of substances into the environment. This also includes the abandonment of closed containers containing hazardous substances, pollutants, or contaminants.

The definition of hazardous substance is extremely broad, and is defined in CERCLA Section 101(14). A comprehensive list of these substances is provided in 40 CFR 302.4. In addition to general listings for “lead”, “lead and compounds”, and “lead compounds,” the regulation lists fourteen other subcategories of lead.

Additionally, CERCLA is not media-specific. Thus, it may address releases to air, surface water, groundwater, and soils. This multi-media aspect of CERCLA makes it possible to conduct environmental assessments and design clean-up projects that address site contaminants in a comprehensive way.

The Agency has pursued a number of CERCLA response actions involving lead-contaminated soil using the abatement authority under Section 106 (which also requires a showing of imminent and substantial endangerment). CERCLA covers almost every constituent found at mining and mineral processing (primary lead and other metals smelters) sites. Exceptions include petroleum (that is not mixed with a hazardous substance) and, in some cases, responses to releases of a naturally occurring substance in its unaltered form. It should be noted, however, that the latter exception does not include any of the releases typically dealt with at mining sites, such as acid mine drainage, waste rock, or any ore exposed to the elements by man.

1.2.2 Response Authorities

CERCLA's main strength is its response authorities. EPA can either use the Superfund to perform response (removal or remedial) activities (Section 104) or require private parties to perform such activities (Section 106). CERCLA gives EPA the flexibility to clean up sites based upon site-specific circumstances. EPA's clean-up decisions generally are based upon both risk assessment and consideration of ARARs. As long as the jurisdictional prerequisites have been met, CERCLA gives EPA the ability to perform virtually any clean-up activity necessary to protect public health and the environment.

There are potential limitations in CERCLA which may be relevant to lead-contaminated sites. For example, Section 104(a)(3) limits EPA’s ability to respond to releases within residential structures as follows:

> "Limitations on Response. The President (EPA) shall not provide for removal or remedial action under this section in response to a release or threat of release . . . from products which are part of the structure of , and result in exposure within, residential buildings or business or community structures . . . "

The above cited section of CERCLA generally limits EPA's authority to respond to LBP inside a structure or house as written in Section 6.6.1 of this Handbook. However as noted in Section 6.6.1 of the Handbook, EPA has the authority to conduct response actions addressing soils contaminated by a release of lead-contaminated paint chips from the exterior of homes to prevent recontamination of soils that have been remediated. In addition, Section 104(a)(4) provides an exception to the limitations in Section 104(a)(3).

CERCLA provides EPA with the authority to perform "removal" and "remedial" actions. Assessments generally are considered "removal" actions and evaluate contaminants of concern, exposure pathways, and potential receptors. The assessment process includes the review of available information, as well as sampling, to obtain other necessary information. The process is broad in its application and is a powerful tool in evaluating environmental risks posed by a site. Removal actions can be performed on mining and mineral processing (primary lead and other metals smelters) sites, and other sites with lead releases to the environment, of any size. Removal actions are subject to limits on time (12 months) and money ($2,000,000) under the statute; however, these limits are subject to exceptions.

Remedial actions are typically long-term responses performed at those sites placed on the NPL. Remedial actions also may be performed at non-NPL sites, through administrative orders on consent (AOCs) or consent decrees, if they are privately financed. Remedial actions are not subject to the time or dollar limitations imposed on removal actions, but require a more detailed and formal decision process.

1.2.3 Applicable or Relevant and Appropriate Requirements (ARARs)

Under Section 121(d) of CERCLA, remedial actions must comply with substantive provisions of federal environmental laws and more stringent, timely identified state environmental or facility siting laws. Removal actions should comply with ARARs to the extent practicable. "Applicable" requirements are those federal or state laws or regulations that specifically address a hazardous substance, pollutant, contaminant, remedial action, location, or other circumstance found at a CERCLA site. "Relevant and appropriate" requirements are not "applicable," but address problems or situations similar enough to those at the CERCLA site that their use is well suited to the site.

State requirements are not considered ARARs unless they are identified in a timely manner and are more stringent than federal requirements. The recently published TSCA §403 Soil Hazard Rule, which establishes a soil-lead hazard of 400 ppm for bare soil in play areas and 1,200 ppm for bare soil in non-play areas of the yard, should not be treated as an ARAR. As recognized in the TSCA §403 Rule, lead contamination at levels equal to or exceeding the 400 ppm and 1,200 ppm standards may pose serious health risks based upon a site-specific evaluation and may warrant timely response actions. However, the soil-lead hazard levels under the TSCA §403 Rule should not be used to modify approaches to addressing brownfields, NPL sites, state Superfund sites, federal CERCLA removal actions and CERCLA non-NPL facilities.

EPA has published a manual outlining potential federal ARARs that may be requirements at Superfund sites. Published in two parts, the manual is entitled *CERCLA Compliance with Other Laws Manua*l, Part I, August 1988, and Part II, August 1989, and is available at EPA libraries (EPA, 1988).

1.3 DEFINITION AND PURPOSE

Residential properties are defined in the Handbook as any area with high accessibility to sensitive populations, and includes properties containing single- and multi-family dwellings, apartment complexes, vacant lots in residential areas, schools, day-care centers, community centers, playgrounds, parks, green ways, and any other areas where children may be exposed to site-related contaminated media (EPA, 1996a, 1997a, 1998a). This document defines sensitive populations as young children (those under 7 years of age, who are most vulnerable to lead poisoning) and pregnant women. Focus is put on children less than 7 years old because blood lead levels typically peak in this age range (EPA, 1986, 1990a; CDC, 1991). Unfortunately, this age range is also when children are most vulnerable to adverse cognitive effects of lead (Rodder, 1995). Pregnant women are included due to the effects of lead on the fetus (Gayer, 1990; Graziano et al., 1990; Carbone et al., 1998). Other EPA guidance (EPA, 1995a, 2001b) and local zoning regulations should also be consulted prior to determining which properties will be treated as residential.

Lead-contaminated residential sites are defined, for the purposes of this document, as sites where lead is the primary contaminant of concern in residential soils. Generally, lead-contaminated sites contain other metals of concern, such as cadmium and arsenic. This document, while addressing primarily lead contamination, may also be appropriate for use in the remediation of sites contaminated by other metals. In all cases, looking at the site history (type of lead site, depositional environment for the lead contamination, fill activities, previous epidemiological studies, etc.) is important in the use of the Handbook. Typically, the types of sites addressed by the Handbook are sites where the lead contamination has resulted primarily from primary or secondary lead smelting, battery cracking, or

mining and milling operations. Lead paint and dust, along with other sources of lead and other toxic metals, may also be present at these sites.

The Handbook is primarily based on a compilation of the Superfund program knowledge and experiences, as well as existing technical and scientific literature addressing lead-contaminated residential sites. The Handbook has undergone broad review by the Agency for Toxic Substances and Disease Registry (ATSDR), the Association of State and Territorial Solid Waste Management Officials (ASTSWMO), and national and regional EPA offices. Because the Handbook is written for use by CERCLA program staff, there are frequent references to guidance or other documents developed under the Superfund auspices. The Handbook does not supersede or modify any existing EPA guidance or policy. This guidance does not suggest that CERCLA authorities are to be applied at all lead-contaminated residential sites. Rather, these references are provided to the reader as resources to be considered in developing site characterization and clean-up strategies under whatever regulatory or non-regulatory approach is appropriate at a particular site. However, the NCP should be followed and other applicable guidance consulted when addressing lead-contaminated residential sites under CERCLA. The Handbook does not address ecological risks from lead and lead sites.

2.0 COMMUNITY INVOLVEMENT

The sustainability of a residential clean-up project in many ways is contingent upon support from affected residents, elected officials, local public health agencies, municipal and public works staff, state government personnel, and other stakeholders. Few sites impact more citizens of a community than large residential clean-up projects, with many projects exceeding a thousand homes and several thousand residents. If the residents recognize the risks posed to their community and feel involved in the decision-making process, they are more likely to accept the need for cleanup. House-to-house personal interaction with residents can be useful to learn their concerns (or lack of concerns) and can also be an effective part of educating the public regarding risks posed by the site. The project manager should issue bulletins and/or fact sheets to help keep the community informed of site activities and should consider establishing a toll free number for residents to contact her/him with questions about the site. Likewise, without the support of local governments, portions, if not all, of the selected remedy may be more difficult to implement. Many remedies rely in part on health education and institutional controls (ICs) as part of the actions taken to protect human health, both of which may rely on the active participation of local governments and health departments. The following sub-sections provide information on involving the community.

2.1 EDUCATION ACTIVITIES

This section discusses how to involve the local health departments and community in the education activities and the overall benefits and limitations of health education. Section 3 addresses health education activities in detail.

Several studies have shown that a significant short-term reduction in blood lead concentrations can be achieved through the education of the public on the dangers of lead exposure and on methods they can take to limit their exposure (Kimbrough et al., 1994; Hilts et al., 1998; Schultz et al., 1999). However, EPA does not consider health education, as the only action, to be an effective, permanent remedy for Superfund sites (Appendix B). Often, in-home education activities have been combined with regular house cleaning. One key to begin reduction of elevated blood lead concentrations in children is to initiate health education activities, and where appropriate, blood lead screening, as early as possible in the process. These activities should be started as soon as elevated blood lead levels or elevated soil levels are detected at a site. Education should be sustained throughout the project. If residual contamination, such as encapsulated wastes, LBP, or other such potential sources are left on site after completion of the remedy, then education activities should be sustained in perpetuity.

Generally, EPA does not directly conduct the majority of education activities. One of the responsibilities of the project manager is to educate the community on the risks of lead exposure and to coordinate with various health agencies in establishing lead education programs. These programs are often implemented by local health districts that, in turn, typically coordinate with schools and other community groups working with families and children. Initial tasks include educating the community regarding their lead exposure and associated health risks. Typically, a significant amount of effort will be required to explain the rationale and procedures of the EPA risk assessment method for lead, using the Integrated Exposure Uptake Biokinetic Model (IEUBK), and the need to collect data to estimate site-specific values for model parameters. It is advisable to obtain input on exposure parameters specific to the community (e.g., how often they frequent locations that are not residential). Community input into the risk assessment is not relevant to those parameters that require site-specific studies to generate empirical data (e.g., an animal feeding study to determine bioavailability). Often, local health officials will be unfamiliar with EPA's risk assessment process and will benefit from education along with the general public. The need for community education is heightened by the subtle nature of the low-dose adverse health effects of lead, which cannot be diagnosed in an individual because the scientific basis for cognitive impairments caused by low to moderate exposures relies on carefully controlled comparisons of large numbers of children exhibiting a range of blood lead levels (NRC, 1993; Needleman and Bellinger, 2001). Once the public and local health officials are made aware of the potential risks presented by the site, specific programs, discussed in detail in Section 3 (Health Education), can be implemented. Education and clean-up activities should be easier to implement, more effective, and more widely accepted by the community when the citizens understand the risks and believe that the community is at risk.

> Integrated Exposure Uptake Biokinetic Model (IEUBK) – Predicts blood-lead concentrations (PbBs) for an individual child, or group of similarly exposed children (6 months to 7 years old), who are exposed to lead in the environment. More information is available from the Technical Review Workgroup for Lead (TRW) web site: http://www.epa.gov/superfund/programs/lead/ieubk.htm

2.2 COMMUNITY ADVISORY GROUPS

Community Advisory Groups (CAGs) can be invaluable in assuring the success of the project (EPA, 1995b). A supporting and active CAG, comprised of a wide cross section of the community, has been demonstrated on several projects to greatly contribute to the success of meeting the remedial goal. Establishing an open dialogue with the CAG

> Community Advisory Group (CAG) – Members of the community make up a CAG, which serves as the focal point for the exchange of information among the local community, EPA, the state regulatory agency, and other pertinent federal agencies involved in cleanup of the Superfund site. Additional information is available online: http://www.epa.gov/superfund/tools/cag/index.htm

and understanding and addressing its concerns, leads to increased satisfaction in the community at the completion of the project. Concurrent with the establishment of health education activities, formation of citizens groups should be encouraged at the very onset of the project. Delay in forming the groups until significant progress has occurred may lead to mistrust by the community, as well as delay or loss of the valuable contributions they can make in assisting EPA.

Citizens groups should be representative of the community. Examples include residents, workers, and business owners from affected neighborhoods, as well as minority leaders, realtors, bankers or lending institution officers, school board members, health officials, elected officials, city public works staff, local environmental group members, and other groups in the community. Additionally, the project manager should coordinate with other federal and state agencies to attend citizen group meetings. Relevant agencies may include the ATSDR, HUD, and state health and environmental departments.

Citizens groups can create a feeling of ownership that facilitates the long-term success of the remedy. They can contribute significantly to education activities in numerous ways. A few examples of the successful programs and activities accomplished by citizens groups at sites include: general education and awareness of the segment of the community they individually represent; creating site-specific education material such as coloring/story books; hosting health fairs; creating health education programs for local school districts; establishing lead poisoning prevention merit badges for girl and boy scout organizations; developing instructional videos; and establishing pre- and post-natal education programs at local hospitals.

2.3 EPA'S TECHNICAL ASSISTANCE GRANT PROGRAM

EPA provides assistance grants to communities to help citizens understand site-related information. By regulation, EPA must inform communities about the availability of Technical Assistance Grants (TAGs) and assist them in applying for these grants (EPA, 1992). EPA also informs citizens about obtaining assistance through other programs such as the university-based Technical Outreach Services for Communities program and the Department of Defense's Technical Assistance for Public Participation (TAPP) program.

Under the TAG program, initial grants of up to $50,000 are available to qualified groups affected by a response action. Additional funding is available for unusually large or complex sites. A group applying for a TAG need not be incorporated as a non-profit organization at the time it submits its application, but must incorporate as a non-profit organization before EPA can award the grant.

The group must contribute 20 percent of the total project costs to be supported by the TAG grant. This requirement can be met in a number of ways, including with cash, donated supplies, and volunteered services. TAG groups must prepare a budget and work plan for using the funds. There may be only one TAG award per NPL site. If more than one group applies for the same TAG, they are encouraged to form a coalition to apply for the grant.

TAGs are used to hire a technical advisor, who is an independent expert who can review site-related documents, interpret them, and explain technical or health-related information to community members. A TAG advisor will often make site visits to gain a better understanding of the clean-up activities. A technical advisor can also help communicate the community's concerns to EPA. TAG funds may not be used to generate new data (e.g., to conduct additional sampling) or for lawsuits or other legal actions. For further information on TAGs, see the recently revised TAG regulation (EPA, 2000b), which is available from the EPA TAG web site.

2.4 INFORMATIONAL MEETINGS

As important as the health education activities and the establishment of citizens groups are, the project manager should consider holding frequent public meetings to inform the community of current and planned EPA activities and to collect feedback and concerns from citizens. If a CAG has been formed at the site, meetings with the group should be frequent and open to the general public. It is recommended that in the early phases of the project, information sessions should be held at least monthly. Once the community becomes aware of the site risks, current site activities, and becomes relatively involved in the process, the frequency of the meetings can be reduced. However, it is recommended that public informational meetings, separate from the citizens task force meetings, be conducted at least once every six months. This frequency can help ensure that the public stays informed of site progress and has an opportunity to provide meaningful input to the process.

In addition to the meetings pursuant to CERCLA (e.g., prior to release of the Record of Decision) meetings are helpful at the following points in the process: (1) before sampling is conducted, to explain the reason that lead contamination is suspected, how residents can reduce exposure as a safety precaution while awaiting sampling results, and the overall goals of the project (e.g., if the goal of the project is to reduce exposure by remediating only surface soils and therefore the sampling is designed to evaluate only surface soils, the issue of ICs for any contaminated soils remaining at depth should be discussed with the property owners early in the process); (2) after sampling is conducted, to explain results, reiterate how residents can reduce exposure (if results show elevated levels), explain plans and the schedule for conducting remediation, discuss plans for re-landscaping the property, and discuss what sort of ICs may be appropriate; and (3) after remediation is completed, to explain what was done, provide documentation

of the results of the remediation, discuss any problems with the landscaping, and discuss any applicable ICs.

2.5 COMMUNITY INVOLVEMENT SPECIALIST/COORDINATOR

When the site is large and cleanup is expected to last several years, consideration should be given to housing a full time community involvement specialist/coordinator (CIS/CIC) at the site. The roles of the CIS/CIC are (1) to coordinate community involvement activities, and (2) to be readily accessible to the public to provide information and answer questions concerning site activities. The CIS/CIC should be intimately familiar with all activities at the site, as well as the documented health risks, and should maintain an office with business hours convenient to the public. Additionally, the CIS/CIC can use information gained from their constant contact with the local community to brief project staff on issues important to the successful remediation of the site.

> Community Involvement Specialist/ Coordinator - is the primary point of contact for a community and a Community Advisory Group (CAG), if one was formed for the site. He or she answers questions and provides other assistance directly as well as sees that a CAG's concerns and other issues are transmitted to other Regional Office staff who can help.

3.0 HEALTH EDUCATION

Health education provides information to the public about the risks associated with exposure to contamination and, in turn, how to reduce the exposures. Health education may be considered one of many tools the project manager can use at lead-contaminated sites to reduce exposure to humans.

3.1 APPROPRIATE USES FOR HEALTH EDUCATION

Health education is an informational device and this type of instrument is largely unenforceable. Furthermore, health education has not been demonstrated to be effective over the longer term. Health education may be effective when combined with other measures as an overall remedy for a site. Health education is not a stand-alone remedy. EPA's policy is that health education is only appropriate as a supplemental component of the permanent, health protective remedy selected at a contaminated lead site.

For these reasons, EPA advocates that health education be layered or implemented in series with ICs and engineered remedies. Layering means using different types of ICs and engineered remedies at the same time to enhance the protectiveness of the remedy. Using ICs in series is the use of ICs at different points in the investigation and remediation process to ensure the short- and long-term protection of human health and the environment.

3.2 PLANNING FOR HEALTH EDUCATION

Generally, the specific goals of the health education program should be described in a site-specific decision document. A plan that clearly defines the goals and how they should be achieved is also more likely to succeed. Health education at large lead sites may have a performance period of several years and cost hundreds of thousands of dollars. For these large projects, a clearly defined health education program is even more important.

An early step in any health education planning process includes conducting a community profile and assessing the educational needs of the community. A comprehensive health education program for a typical large lead site would normally attempt to focus on reaching the general public, with special emphasis on schools and other groups involved with young children. Also, it is important to coordinate with city, county, and other local governmental entities. The most important target population, though, is parents, particularly young parents, and parents with a child whose blood lead tested high. Other means of targeted education may include those homes with children that have high dust lead concentrations or lead loadings, which have been shown to be highly predictive of homes where a child is likely to have an elevated blood lead level during the summer peak (EPA, 1996b; von Lindern and Spalinger, 2001).

The response plan should describe what actions and activities are necessary to reach the community-at-large and the targeted groups. It is very important to consider that there are costs associated with the development, implementation, and follow up of health education and that these factors should be thoroughly understood and estimated. Other key points to consider are that the responsibilities for conducting this work should be clear and agreements should be made in writing in the planning stages of site response process.

3.3 EVALUATION OF HEALTH EDUCATION ACTIVITIES

It is important to monitor the effectiveness of health education projects that have been implemented at lead-contaminated sites. Many sites may include health education activities as a major component of the remedy, especially in the early phases of the cleanup. Failure to establish the education part of the remedy may trigger reconsideration and imposition of additional requirements, or more extensive and costly clean-up efforts.

The project manager should monitor the organization(s) performing the educational activities for proper implementation of the health education program and assess the effectiveness of the program. Project managers should ensure that the objectives of the program are being met to protect children's health. If health education is included as part of the final remedy, it should be carefully scrutinized during the Five-Year Review process.

3.4 AGENCY FOR TOXIC SUBSTANCES AND DISEASE REGISTRY (ATSDR) INVOLVEMENT

Health education is often implemented through grants from ATSDR to its partners in state health departments or directly through agreements with local health departments. When health education is specified as a major part of EPA's clean-up activities, strong consideration should be given to establishing an interagency agreement with ATSDR to assist in funding the required activities. ATSDR as a federal health agency is well positioned in terms of health education resources to administer such grants. ATSDR can provide expertise not only with the CAGs but also with public health assessments, health consultations, and health surveillance. An emphasis should be placed on developing the collaborative partnerships between EPA, ATSDR, and other federal, state, and local health departments for health education activities at contaminated lead sites.

Health education at lead sites is often accompanied with blood lead screening. Centers for Disease Control and Prevention (CDC) has issued guidelines for increasing intensity of health intervention activities based on blood lead test results (CDC, 1991). Increased collaboration among the involved

agencies is important to properly implement a health education/blood lead screening project. Additionally, ATSDR and many state and local health departments have ongoing lead screening and health education programs. Information from targeted screening is valuable for (1) targeting follow-up education to individual families with children identified with elevated blood lead levels; (2) determining the areal and demographic extent of the problem; and (3) effectively evaluating the impact of health education.

3.5 OUTREACH

EPA has had success in health education activities at several sites because the programs were tailored specifically for the site by the site team (i.e., project manager, toxicologist, on-scene coordinator, CIS/CIC, etc.). These programs have included significant amounts of outreach activities in the communities. The success of any health education program generally can be attributed to the amount of community outreach that is conducted at the site. As discussed in Section 2, the outreach can consist of a wide variety of activities. A few examples include the following: site specific coloring books distributed to the parents of young children, scouting merit badges on lead-poisoning prevention, school curriculums developed to inform student of the hazards of lead and good hygiene, health and environmental fairs conducted in the community, and blood lead testing events held at community celebrations. Consultation with local health officials and community groups can provide numerous ideas for outreach, which can be incorporated into specific programs to best meet the needs of the community. Typically, the local health officials should lead the outreach efforts. Funding should be provided by EPA when other funds, such as from ATSDR, are unavailable to support the outreach activities.

4.0 SITE CHARACTERIZATION

EPA has reviewed various sampling designs historically employed at lead-contaminated residential sites and assessed the ability of these sampling designs to meet risk assessment needs and support the development of clean-up levels. Over a 20-year period, several large area lead sites (e.g., Bunker Hill, Shoshone County, Idaho; Joplin, Missouri; NL Industries/Taracorp-Granite City, Illinois; Tar Creek, Ottawa County, Oklahoma) have used a variety of sampling techniques to characterize residential properties. Additionally, many different approaches to applying selected clean-up levels have been taken. As stated, this document was developed to promote consistent procedures, criteria and goals in the investigation and clean-up activities at Superfund lead-contaminated residential sites. However, a level of flexibility is needed to best respond to different site conditions, communities, and uncertainties.

The overall goals of the sampling effort are to estimate an average soil lead concentration for risk assessment purposes and to provide information to determine the scope of any required clean-up actions. This information can also be used for public education and intervention. The sampling designs discussed in this section are intended to provide, within one sampling effort, the necessary data for all phases of a clean-up project so that residents are not inconvenienced by repeated sampling of the same property. Project managers should carefully choose the sampling points needed to estimate the average lead concentration in a cost-effective manner. Some uncertainty is acceptable to reduce the overall cost of sampling at large lead sites. The selection of sample locations within areas with potential for exposure has been the subject of recent articles which describe methods to manage decision uncertainty by balancing sampling and clean-up costs (Englund & Heravi, 1994; Crumbling et al., 2001). Table C-1 (Appendix C) lists contacts within the agency who can provide assistance in various aspects of sample planning and design, and also lists software that may be used for sample planning and decision support.

Section 4.0 discusses: (1) delineating the contamination zones; (2) residential property sampling locations; (3) sampling method; (4) sampling requirements for backfill material and excavated soil for off-site disposal.

4.1 CONTAMINANT ZONE DELINEATION

Historical information on site operations and use is crucial for the design of sampling plans that are intended to delineate contaminant zone(s), and for the interpretation of data generated from the sampling effort. In addition to gathering data on the nature of the source of contamination, information should be gathered to identify areas where soils may have been moved or where fill or topsoil may have been placed. Guidance on how to gather historical site data is available (EPA, 2001f, 2001g). Sites that have been contaminated primarily by airborne-derived lead, such as smelter areas, can initially be sampled in a

grid pattern. This will usually allow concentration contours to be defined across the community and to establish the extent of horizontal contamination for cleanup and costing purposes. If grid sampling is used for initial characterization to define the horizontal extent of contamination, follow-up sampling of each yard located within the identified clean-up zone should be used to characterize each individual property for clean-up requirements. For other sites where the variability is expected to be higher, such as mining sites with discrete individual tailings piles located throughout the area, delineating the contaminant zones by establishing concentration contours will be more uncertain and consideration should be given to sampling every home in the potentially affected area, moving laterally away from the source until clean areas of the community have been identified.

Delineating the zone of contamination generally amounts to distinguishing soil with "background" lead concentration from soil that has been impacted by site-related activities. There are basically two types of background: naturally occurring and anthropogenic (see insert for definitions) (EPA, 1989, 1995c, 2002). EPA guidance defines background for inorganics as *"...the concentration of inorganics found in soils or sediments surrounding a waste site, but which are not influenced by site activities or releases"* (EPA, 1995c). Natural background concentrations of lead vary widely with the local geology, and can be as high as 250 ppm or more in mining areas (SRC, 1999). Local background concentrations, which include natural and non-site-related anthropogenic sources (e.g., historic automobile emissions) can be substantially higher. Background samples should be collected from areas near the site that are not influenced by site contamination, but that have the same basic characteristics (e.g., soil type, land use).

Types of Background

naturally occurring: ambient concentrations of lead present in the environment that have not been influenced by humans

anthropogenic: lead concentrations that are present in the environment due to human-made, non-site sources (e.g., automobile exhaust)

Statistical approaches to delineating contaminant zones are useful for some sites. In these cases, the project manager should consult with a statistician to design an efficient sampling plan. The Agency is developing guidance on characterizing background chemicals in soil that includes statistical methods for delineating contaminated areas (EPA, 2001i). Geostatistics is widely recognized for offering graphical methods that are ideally suited for delineating contaminant zones (Gilbert and Simpson, 1983; Flatman and Yfantis, 1984; Journel, 1984; Englund and Heravi, 1994; Goovaerts, 1997). Geostatistics also provides powerful methods for detecting contaminated areas from background when sample locations have not been randomly selected (e.g., Quimby, 1986; Borgman and Quimby, 1996), for sampling plan design (e.g., Flatman and Yfantis, 1984; Borgman et al., 1996), and for aiding in the design of remedial

responses (e.g., Ryti, 1993). For smaller sites, rigorous statistical analyses may be unnecessary because site-related and non-site-related contamination clearly differ. For these sites, the sampling plan should focus on establishing a reliable representation of the extent (in two or three dimensions) of a contaminated area (EPA, 1989) .

4.2 RESIDENTIAL PROPERTIES

For the purposes of this document, a residential property includes properties that contain single and multi-family dwellings, apartment complexes, vacant lots in residential areas, schools, day-care centers, playgrounds, parks, and green ways (EPA, 1996a, 1997a). In all cases, historical site information (type of lead site, fill activities, previous epidemiological studies, etc.) is important in the application of this Handbook.

Rationale for collecting yard soil samples and water samples on a residential property is provided in Table 4-1. The collection of other types of media are important to determine overall risk, however CERCLA has limited authority to address these media (e.g., interior paint, dust, and potable water).

4.2.1 Sampling Access

Prior to conducting any sampling or clean-up activities at a residential property, access must be obtained from the property owner; access obtained from tenants or renters is not sufficient. It is essential to begin access procurement as early as possible in the remedial process to avoid potentially lengthy delays. It is recommended that access be obtained by going door-to-door. If residents are not home, a blank access agreement with instructions for signature and submission to EPA, along with relevant contact information should be left at the residence (but not in the mailbox). Examples of access agreements are presented in Appendix D, pages D-2 and D-3. If possible, access for remediation should be obtained at the same time access for sampling is sought. Examples of combined sampling/remediation access agreements are included on pages D-4 and D-5 of Appendix D. Combining sampling and clean-up access will avoid potentially lengthy delays. Additionally, access should be obtained for any interior dust sampling and/or cleaning that will be performed at the residence (Section 6.6.2). Sample access agreements for dust cleanup are presented in Appendix E.

Table 4-1.
Rationale for Sampling Residential Properties

Sample Location	Rationale for Sample Collection
Residential yard soils	Residential soil may present a direct exposure pathway to persons working, playing, or conducting other recreational activities on the property. Soil samples should be collected and quantitatively analyzed to estimate lead concentrations. Residential soils may also present an indirect exposure pathway via house dust exposure (see below).
Gravel driveways	Fine-grained driveway material may present a direct exposure pathway to persons working or engaged in recreational activities on driveways. Soil samples should be collected and quantitatively analyzed to estimate lead concentrations. Gravel driveways with elevated soil concentrations may also contribute to the transport of contaminants throughout the community.
Drip zones and soils below roof gutter downspouts	Rooftops may collect fine-grained sediments that contain high concentrations of lead. In yard areas where downspouts discharge during a storm event, the fine-grained material washed from a roof may accumulate and result in a localized increase in soil lead concentrations. Soil samples should be collected and quantitatively analyzed to estimate lead concentrations. Drip zone areas may also contain LBP influences and are important to characterize for health intervention purposes, as drip zones are often used as play areas.
Soils in play areas	Play area soils may present a direct exposure pathway to children under the age of seven. Soil samples should be collected and quantitatively analyzed to estimate lead concentrations.
Garden soils	Garden soils may present a direct exposure pathway to persons who actively maintain a garden. Soil samples should be collected and quantitatively analyzed to estimate lead concentrations.
Interior lead dust	Lead in household dust may be a significant contributor to elevated blood lead levels, especially in younger children. Dust samples should be collected and quantitatively analyzed to estimate lead concentrations. Lead-contaminated interior dust can be derived from multiple sources; dust mat samples and speciation can be used to identify lead sources.
Lead-based paint	Deteriorating LBP may contribute lead to household dust, which can be a significant source of lead exposure, particularly for young children. If elevated concentrations of lead are found in interior dust, samples of interior paint should be collected and quantitatively analyzed to estimate lead concentrations. Exterior LBP may contribute to the recontamination of remediated properties. Samples of exterior LBP should be collected and quantitatively analyzed to estimate lead concentrations.
First run and purged tap water	Groundwater and surface water near the site may contain elevated lead concentrations. Some residences located within the site may use local groundwater or nearby surface water as a source of drinking, cooking, bathing, or irrigation water. The water may represent a direct exposure or ingestion pathway. Samples of both water standing in the pipes (first run sample) and water discharged after the system has been flushed (purged sample) should be collected and quantitatively analyzed to estimate lead concentrations. These results can also be used to help determine if the drinking water is contaminated with site-related contamination (exceedance in purged), or to determine if there is lead in the home's plumbing (exceedance in first run), or both, which may be used for remediation or intervention purposes, respectively.
Crawl Spaces	Crawl space sampling is recommended if the crawl space is accessible to children or pets. At some sites (e.g., Bunker Hill) this has been found to be a significant pathway (IDHW, 2000; TerraGraphics, 2000). Even when spaces are too small for children, pets have been found to access these spaces and move significant amounts of fine dust containing elevated lead levels into the child's bedroom (e.g., where a pet may sleep on the child's bed at night). Information on concentrations of lead beneath the structure may be used to document the need to preclude access or take other remedial measures.
Other areas	During field work, other potential sources of lead contamination may be identified. If the sources appear to represent a potential exposure pathway to occupants of a residence, sampling may be recommended. Other areas should be evaluated on a case-by-case basis and could include sediment, surface water, or secondary play areas. If deemed appropriate, samples should be collected and quantitatively analyzed to estimate lead concentrations.

4.2.2 Residential Yards

It is recommended that when sampling residential lots with a total surface area less than 5,000 square feet (a typical urban lot size), five-point composite samples should, at a minimum, be collected from each of the following locations: the front yard, the back yard, and the side yard (if the size of the latter is substantial). The front, back, and side (if needed) yard composites should be equally spaced within the respective portion of the yard, and should be outside of the drip zone and away from influences of any other painted surfaces (Figures 4-1a and 4-1b). Composites should consist of aliquots collected from the same depth interval.

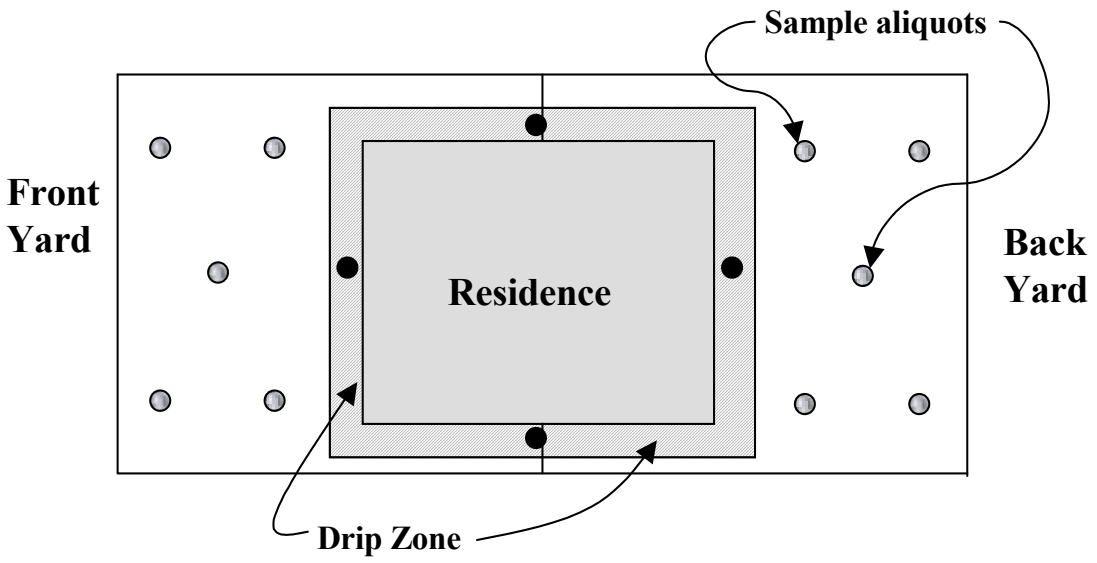


Figure 4-1a. Recommended minimum soil sampling in yards less than or equal to 5,000 square feet with small side yard. Five point composite samples should be collected from each of the front and back yards. Four point composites should be collected from the drip zone; each aliquot should generally be collected from the midpoint along each side of the residence. Aliquots for a single composite sample should be collected from the same depth interval. Soil samples should also be collected from distinct play areas and gardens if they are present, as well as unpaved driveways and minimal use areas such as areas under porches and crawl spaces. The locations of the aliquots should be equally spaced within the area of the yard the composite is collected from. The figure illustrates one possible arrangement of the sample aliquots. Please refer to Section 4.2.2 for further explanation.

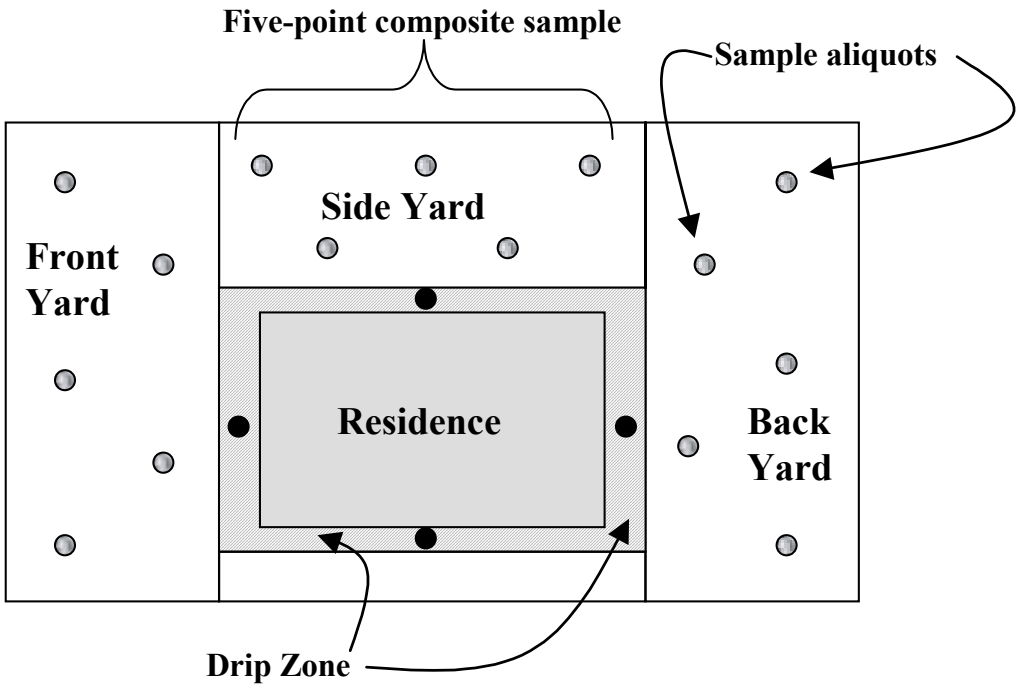

Figure 4-1b. Recommended minimum soil sampling in yards less than or equal to 5,000 square feet with substantial side yard. Five point composite samples should be collected from each of the front, back, and side yards, along with other areas as described in Figure 4-1a. The locations of the aliquots should be equally spaced within the area of the yard the composite is collected from. The figure illustrates one possible arrangement of the sample aliquots Aliquots for a single composite sample should be collected from the same depth interval. Please refer to Section 4.2.2 for further explanation.

For residential lots with a total surface area greater than 5,000 square feet, it is advisable that the property be divided into four quadrants of roughly equal surface area. The two quadrants in the front yard should encompass one half of the side yard; likewise for the two quadrants in the back yard. One five-point composite of aliquots collected at equal spacing and from the same depth interval should be obtained from each quadrant. Each aliquot should be collected away from influences of the drip zone and any other painted surfaces (Figure 4-2).

Properties over one acre in size should be divided into 1/4 acre sections. One five-point composite sample should be collected from each section. For large properties, consideration should be given to whether elevated concentrations trigger partial removal of soils or access restriction (see Section 6.5).

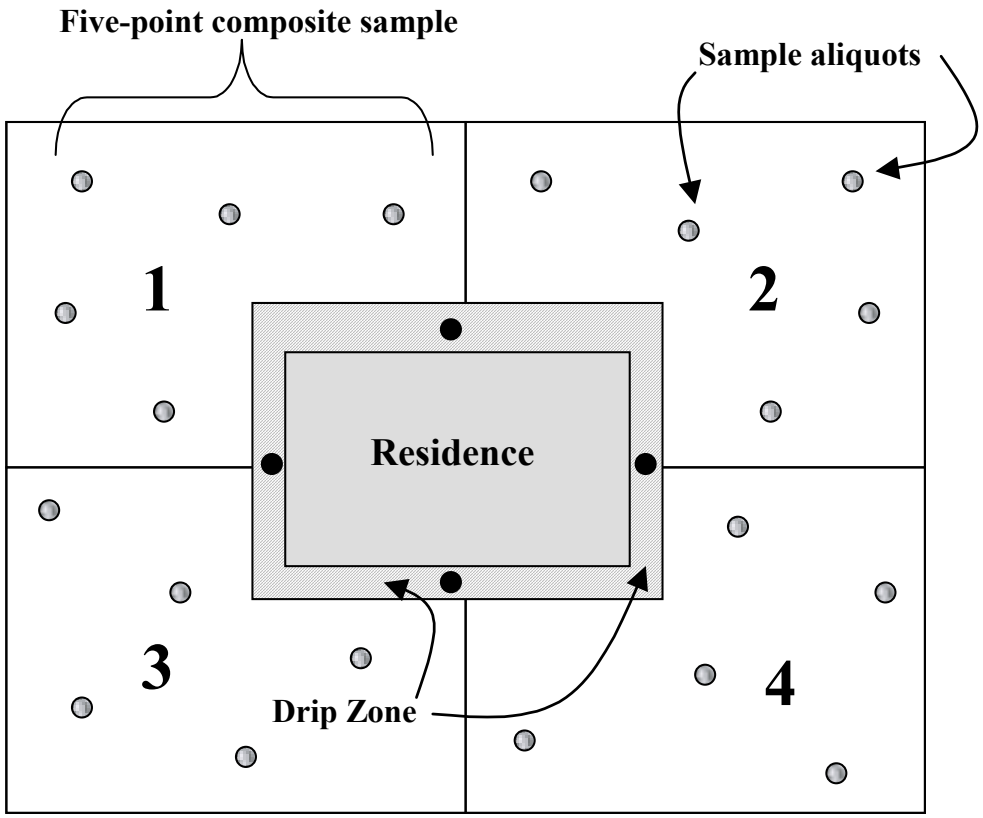

Figure 4-2. Recommended minimum soil sampling in yards greater than 5,000 square feet. Five point composite samples should be collected from each of the four quadrants as indicated above. The locations of the aliquots should be equally spaced within each of the quadrants. The figure illustrates one possible arrangement of the sample aliquots. Four point composites should be collected from the drip zone; each aliquot should generally be collected from the midpoint along each side of the residence. Aliquots for a single composite sample should be collected from the same depth interval. Additional samples should be collected from distinct play areas and gardens if they are present, as well as unpaved driveways and minimal use areas such as areas under porches and crawl spaces. Please refer to Section 4.2.2 for further explanation.

4.2.3 Drip Zones

Lead-contaminated soils are frequently found within the drip zone of houses. It is recommended that a four-point composite sample be collected from the drip zone of each residential property (Figures 4-1a, 4-1b, and 4-2). The composite sample (taken from any size lot) should consist of a minimum of four aliquots collected between 6 and 30 inches from the exterior walls of the house. Each aliquot should generally be collected from the midpoint of each side of the house. Collection of additional aliquots should be considered if other factors exist, such as bare spots, distinct differences in the house exterior, and areas where runoff collects. Rooftops may collect fine-grained sediments that contain high concentrations of lead. In yard areas where downspouts discharge during a storm event, the fine-grained material washed from a roof may accumulate and result in a localized increase in soil lead

concentrations. Samples of the soil from the downspout discharge area should also be sampled if present.

4.2.4 Play Areas, Gardens, and Driveways

Distinct play areas and gardens, if present, should generally be sampled separately as discrete areas of the yard. At some sites, collection of a right-of-way/easement composite may also be appropriate, such as residential areas with unpaved streets and alleys. Paved surfaces such as asphalt/concrete driveways, patios, alleys, and parking lots should, in most cases, not be sampled. Samples should also be collected in other locations depending upon the potential for exposure or recontamination, for example, under porches and crawl spaces and areas with incomplete barriers such as gravel driveways.

4.2.5 Potable Water, Lead-Based Paint and Interior Dust

Drinking water supply samples should be collected to determine if exposure to lead in drinking water is occurring. First-run and purged samples of potable water should be collected to differentiate site-related sources of lead from lead derived from plumbing that is located within the residence. CERCLA authority for remedial action may be limited with regard to lead derived from plumbing that is located within the residence.

Deteriorating LBP may contribute lead to household dust. If elevated concentrations of lead are found in interior dust, samples of interior paint should be collected. Exterior LBP may contribute to the recontamination of remediated properties (Section 6.7). Samples of exterior LBP should be collected and analyzed to estimate lead concentrations. Lead in household dust may be a significant contributor to elevated blood lead levels, especially in younger children. Lead-contaminated interior dust can be derived from multiple sources; dust mat samples and speciation can be used to identify lead sources. Dust samples should be collected and analyzed to estimate its potential contribution to lead exposure. Guidance on LBP and dust sampling is available from HUD (HUD, 1995).

4.2.6 Backfill and Waste Soil

Backfill soil should be sampled to ensure that uncontaminated material is being placed on the site. The list of analytes and the frequency of sampling should be based on site-specific factors including the location of the source for the backfill material relative to potential sources of contamination, the geology of the borrow area, and the heterogeneity of the material. For example, on the Bunker Hill Superfund Site, four-point composite samples were collected for each 200 yd^3 of soil (TerraGraphics, 1997a). Gravel for driveway backfill was also sampled every 200 yd^3 (TerraGraphics, 1997b). Samples of excavated soil should be analyzed by the toxicity characteristic leaching procedure (TCLP) method to

determine the appropriate method of disposal. The frequency required for TCLP sampling should be based on the heterogeneity of the lead and other contaminant(s), if any, on the site.

4.3 SAMPLING METHOD AND ANALYSIS

4.3.1 Sample Collection

Composite samples should consist of discrete aliquots of equal amounts of soil. The soil from each aliquot should be collected into one clean container, such as a stainless steel bowl or plastic bag, and thoroughly mixed. After mixing, the sample can then be analyzed by X-Ray Fluorescence (XRF) (see Section 4.3.4) or sent to the laboratory. Remaining sample volume can then be disposed in the general location from where it was collected, or archived, depending on the requirements of the project. In some cases, material other than grass and/or soil will be encountered at a sample location, e.g., wood chips and sand are often found in recreational areas of day-care and school playgrounds. Samples of the soil below the cover material should be collected.

The use of a dynamic sampling and analysis strategy should be considered (EPA, 2001d). A dynamic sampling and analysis strategy takes full advantage of the real-time that data field analytical methods provide, which can limit the sampling effort and minimize cost (EPA, 2001d). This document suggests the use of field portable X-Ray Fluorescence (FP-XRF) analysis.

4.3.2 Sample Depth

The following sampling design is based on the assumption that removal of surficial contaminated soils and placement of a cover of clean soil will be protective of human health and the environment (see Section 4.0). Furthermore, the sampling design outlined below is based on the assumption that a minimum of 12 inch soil cover is adequate.

Initial sampling for lead contamination in residential soils should be conducted to a depth of at least 18 inches, but does not need to exceed 24 inches to define the vertical extent of contamination for clean-up purposes. Composite samples should be collected at 6 inch depth intervals, i.e., 0–6 inches, 6–12 inches, 12–18 inches, and 18–24 inches. Additional sampling may be required at lead sites in cold weather regions when contamination is associated with coarse grained material. Stone-sized material, such as tailings and crushed battery casings, will, over time, migrate upward through the soil via freeze/thaw effects. At such sites, composite sampling should be conducted at 6 inch intervals to the approximate maximum frost depth for the region. In all cases, composites should consist of aliquots collected from the same depth interval.

In site-specific situations, deeper sampling may be conducted to determine the total vertical extent of contamination for groundwater issues or ICs, and to determine if complete removal of contaminated soil is possible. Depth sampling should be conducted until the vertical extent of contamination has been adequately defined, but does not need to be conducted on every property.

In addition to the composite samples collected to define the vertical extent of contamination, five-point composite surface soil samples should be collected from 0 to 1 inch for human health risk assessment purposes (EPA, 1989, 1996c). The samples should be collected using the procedure described in Section 4.3.1. These surface soil samples should be collected from every property within the identified zone of contamination; however, after collecting a statistically valid number of both 0–1" and 1–6" samples, the project manager may want to compare both sample horizons (e.g., paired-sample t-test; Wilcoxon Rank Sum test) (Gilbert, 1987; Snedecor and Cochran, 1989) to determine if the 0–1" depth can be eliminated (i.e., sample from 0–6"), to further decrease sampling costs. This may be particularly useful at mine waste sites where contamination often extends to depth or at sites where lead-contaminated soil has been used as fill material; in such cases, the lead concentration may increase with depth. Conversely, the 0–1" horizon may be far more contaminated than the 1–6" at smelter sites, making individual horizon sampling crucial to remedial decision-making.

Collection of samples from specified depth intervals serves two primary purposes: risk assessment and remedial decision-making. With respect to risk assessment, the top inch of soil best represents current exposure to contaminants (EPA, 1989, 1996c) and is the source of data used in the IEUBK model to represent exposure from soil. The various depth intervals are used in remedial decision-making to determine if a residential yard requires cleanup by evaluating if any of the horizons exceed the site-specific action level. The lower soil horizons represent possible future exposures, such as homeowner projects, children's play areas, and other home activities that periodically go beneath the top inch of vegetation/soil (EPA, 1989). All soil horizons should be used for clean-up decision-making. The 6 inch depth intervals recommended in this document are based on the performance that may be reasonably expected of operators of small equipment working in relatively small spaces around homes. Specifically, a "bobcat" is most efficiently used for soil removal on a property if the soil is removed in 6 inch intervals, rather than in smaller increments, which would be far more difficult to achieve in a consistent or cost-effective manner. This approach has been developed to ensure a residential yard is cleaned up if it poses an immediate or long-term risk to human health in a manner that relates the sampling methodology closely to reasonable and cost-effective construction equipment performance.

A secondary goal of the sample collection effort is to facilitate the implementation of ICs for sites where contamination at depth is left in place.

4.3.3 Sample Preparation

Residential soil lead samples should represent the exposure potential of young children who are most vulnerable to adverse effects of exposure. Children inadvertently ingest lead in soil and dust that adheres to their hands (Succop et al., 1998). The smaller particles are more representative of this type of exposure (Duggan et al., 1985; Kissel et al., 1996; Mielke et al., 1997). Additionally, smaller particles are preferentially brought into the home. Sieving is conducted to better represent the soil fraction that is ingested by the typical child. Sieving has also been used in soil ingestion and bioavailability studies (Calabrese et al., 1996; Casteel et al., 1997; Stanek et al., 1999). Samples collected from all depth intervals should be sieved. Samples should not be ground prior to sieving, as this changes the physical structure of the soil and may bias the analytical results. To reduce sampling costs, it may be desirable to develop a correlation between sieved and unsieved data, to eliminate the need to sieve all samples. The correlation can be used to predict sieved results from unsieved samples. The EPA Technical Review Workgroup (TRW) and American Society for Testing and Materials (ASTM) have issued guidance on sieving (ASTM, 1998; EPA, 2000c). The EPA TRW guidance addresses appropriate sieve size (No. 60) and a method for predicting the concentration in the fine fraction using concentrations measured in unsieved samples.

Technical Review Workgroup (TRW) – The TRW is an interoffice workgroup that consists of key scientific experts from various EPA regions, labs, and headquarters that supports and promotes consistent application of the best science in the field of lead (Pb) risk assessment at contaminated sites nationwide.

The presence of paint chips in a soil sample can represent a large proportion of the total lead concentration that is measured. On this issue, the Handbook directs the reader to existing HUD guidance, which states “If paint chips are present in the soil, they should be included as part of the sample. However, there should be no special attempt to over-sample paint chips. The laboratory should be instructed to disaggregate (‘break up’) paint chips by forcing them through a sieve in the laboratory. Although paint chips should not be oversampled, they should not be excluded from the soil sample, since they are part of the soil matrix.” (HUD, 1995). The TRW website should be checked periodically for additional sampling guidance.

4.3.4 Sample Analysis

EPA’s experience in sample analyses at large residential contamination sites (with several thousand homes on a site) shows that both FP-XRF or fixed-site laboratory analyses (acid digestion/Inductively Coupled Spectroscopy) provide reliable information (EPA, 1996d, 1998b, 2001c, 2001d; Crumbling et al., 2001). The objective of using a FP-XRF is to predict Contract Laboratory Program (CLP) values with

less expensive real-time data. A sufficient amount of data should be collected to develop a site-specific relationship (i.e., correlation) between FP-XRF and CLP lab data.

The comparison should consider sample preparation (drying and sieving) and analytical methods. Typically, a large number of laboratory confirmation samples should be analyzed at the beginning of the project to estimate the correlation between the FP-XRF and the CLP results and the FP-XRF precision and accuracy. Additional confirmatory samples should then be analyzed at key decision points when the FP-XRF results are close to action levels or when the reliability of the FP-XRF unit is in question (EPA, 2001d). For example, initial sample analyses using an FP-XRF instrument could include 20 percent laboratory confirmatory samples to assess the accuracy and precision of the FP-XRF. Once the accuracy and precision of the FP-XRF results have been determined (and assuming they satisfy the requirements of the project), the number of laboratory confirmatory samples could be reduced (e.g., to 5 percent). Additional information on analyzing soil (and other media) in the field with FP-XRF is available on the EPA web site: http://www.epa.gov/superfund/programs/dfa/ (EPA, 2001e).

Proper calibration of the FP-XRF unit is important to obtaining reliable results (EPA, 1996d). Correlation between the FP-XRF and laboratory analyses is best achieved with small sample volume. Laboratory confirmatory samples should be collected in the specimen cup available from the FP-XRF manufacturer. The sample is first analyzed with the FP-XRF and then sent to the laboratory for wet chemistry analysis. Soil moisture can introduce error in FP-XRF results to varying degrees, depending on the instrument being used (EPA, 1996d). The correlation between the FP-XRF measurements on dried and undried samples should be estimated. The correlation analysis should then be used to establish a cutoff or ‘soil moisture ceiling’. The ‘soil moisture ceiling’ represents the maximum moisture content at which useful results (i.e., of sufficient precision and accuracy) can be obtained with the FP-XRF. Field portable instruments capable of measuring moisture content are available and should be used to compare sample moisture content to the ‘soil moisture ceiling’. Samples with moisture contents greater than the ‘soil moisture ceiling’ should be dried prior to analysis with the FP-XRF.

5.0 CLEAN-UP LEVEL SELECTION

Generally, the approach to human health risk assessment for lead differs from that of other metals and contaminants. Typically, risks from lead exposures are estimated from long-term exposures, although elevated blood lead concentrations also result from short-term exposures (CDC, 1991). EPA has developed the IEUBK model to predict blood lead (PbB) concentrations in children exposed to lead. The model considers several different media through which children can be exposed to lead.

EPA and the CDC have determined that childhood PbB concentrations at or above 10 micrograms of lead per deciliter of blood (: g Pb/dL) present risks to children's health (CDC, 1991). Accordingly, EPA seeks to limit the risk that children will have Pb concentrations above 10 : g Pb/dL. The IEUBK model predicts the geometric mean PbB for a child exposed to lead in various media (or a group of similarly exposed children). The model also calculates the probability that the child's PbB exceeds 10 : g Pb/dL (P_{10}). Preliminary remediation goals (PRGs) generally are determined with the model by adjusting the soil concentration term until the P_{10} is below 5%. Final clean-up level selection for Superfund sites generally is based on the IEUBK model results and the nine criteria analysis per the National Contingency Plan (NCP) (EPA, 1990b), which includes an analysis of ARARs. More information on the IEUBK model is available from the EPA TRW web site.

Typically at large lead sites, early actions taken to mitigate the identified site risks consist of time-critical removal actions (TCRAs), most often taken as an interim action. These actions are usually followed by long-term remedial actions. The following sections describe the different approaches that should be used for prioritizing response actions and selecting clean-up levels for both early (interim) and long-term (permanent) response actions.

5.1 PRIORITIZING RESPONSE ACTIONS

For early, interim actions, a tiered approach should be used for prioritizing clean-up actions. A tiered-response approach is recommended when sufficient resources are not available to fully address lead risks. The size and complexity of many lead sites often requires implementation of response actions over an extended period of time; therefore, it is often necessary to implement interim clean-up actions to manage short-term health risk concerns while response actions to address long-term risk are planned and implemented. Early removal actions at residential lead sites should contribute to the performance of the long-term permanent remedy.

The tiered approach is depicted in Figure 5-1. Figure 5-1 is a flowchart that provides a roadmap of the recommended clean-up process for lead-contaminated residential sites. An overview to the clean-up process is provided in Figure 1-1. The first page of Figure 5-1 provides a more detailed overview; the subsequent pages provide additional details of the process.

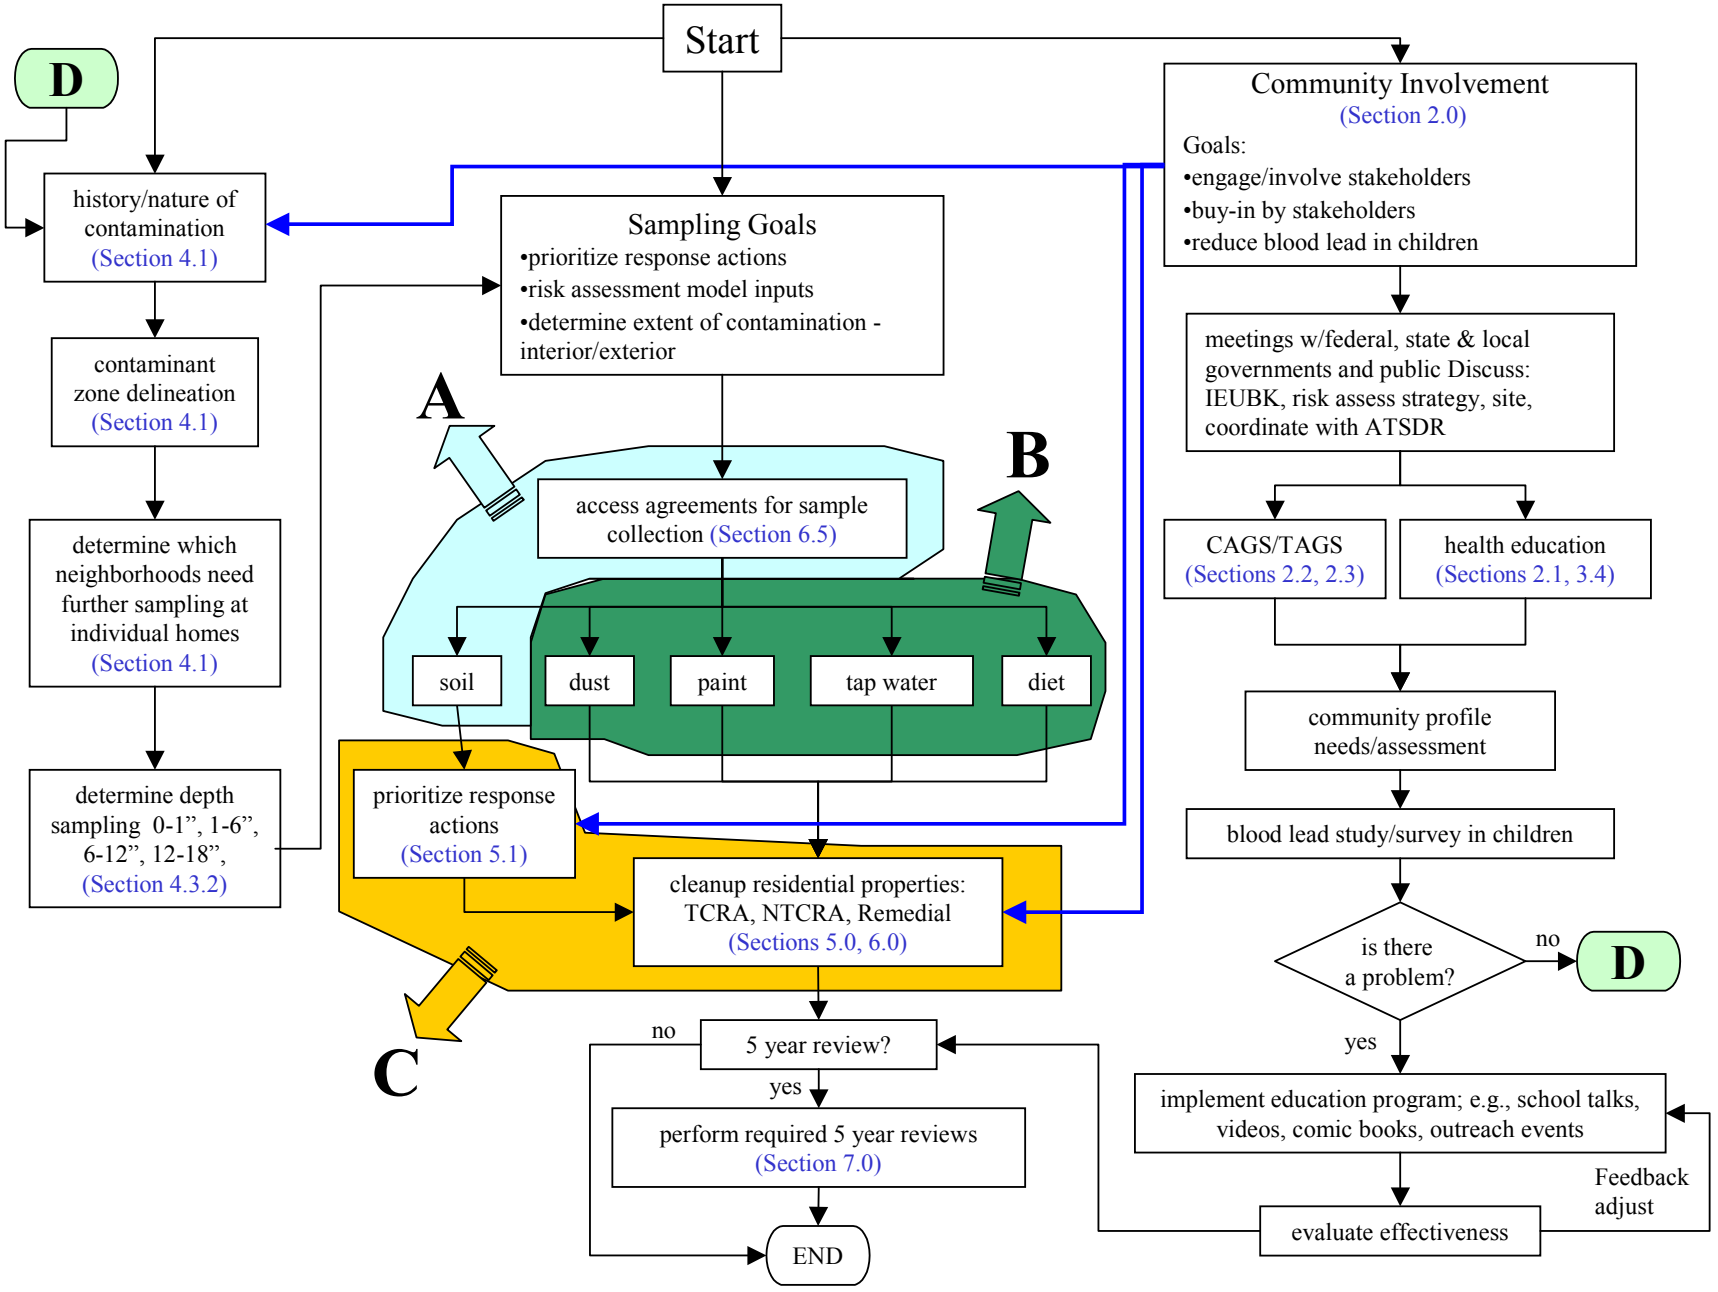

Figure 5-1. Recommended clean-up process for lead-contaminated residential sites. Refer to Figure 1-1 for an overview of the process. The shaded portions of the figure, labeled A-C, are expanded on the second through the fourth pages of the flowchart.

Figure 5-1. (continued)

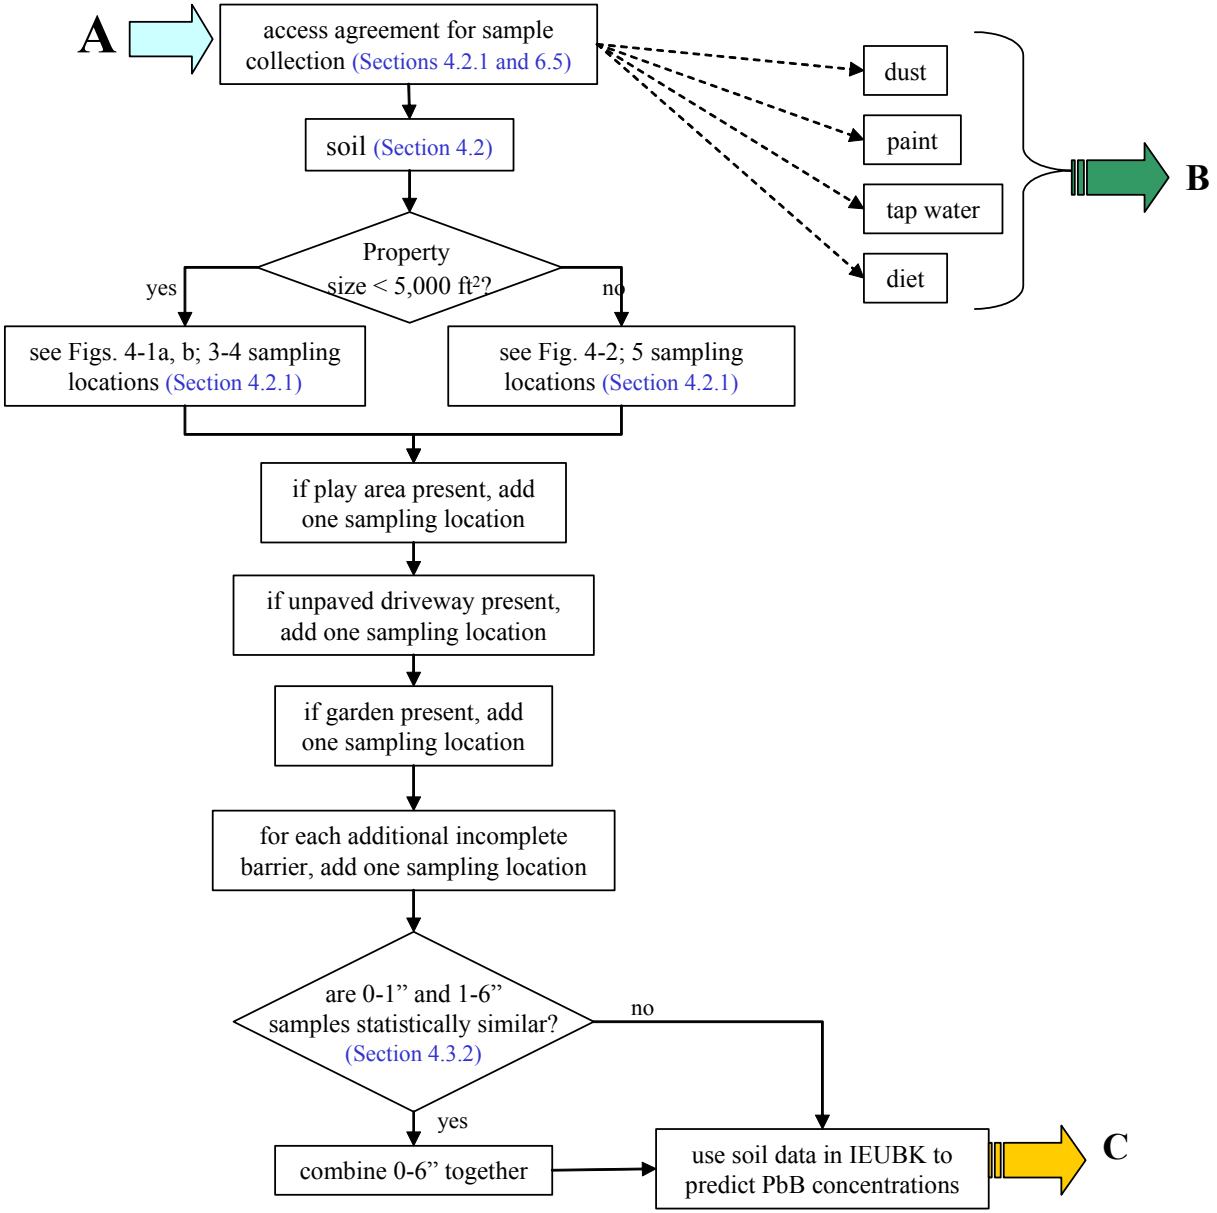

Figure 5-1. (continued)

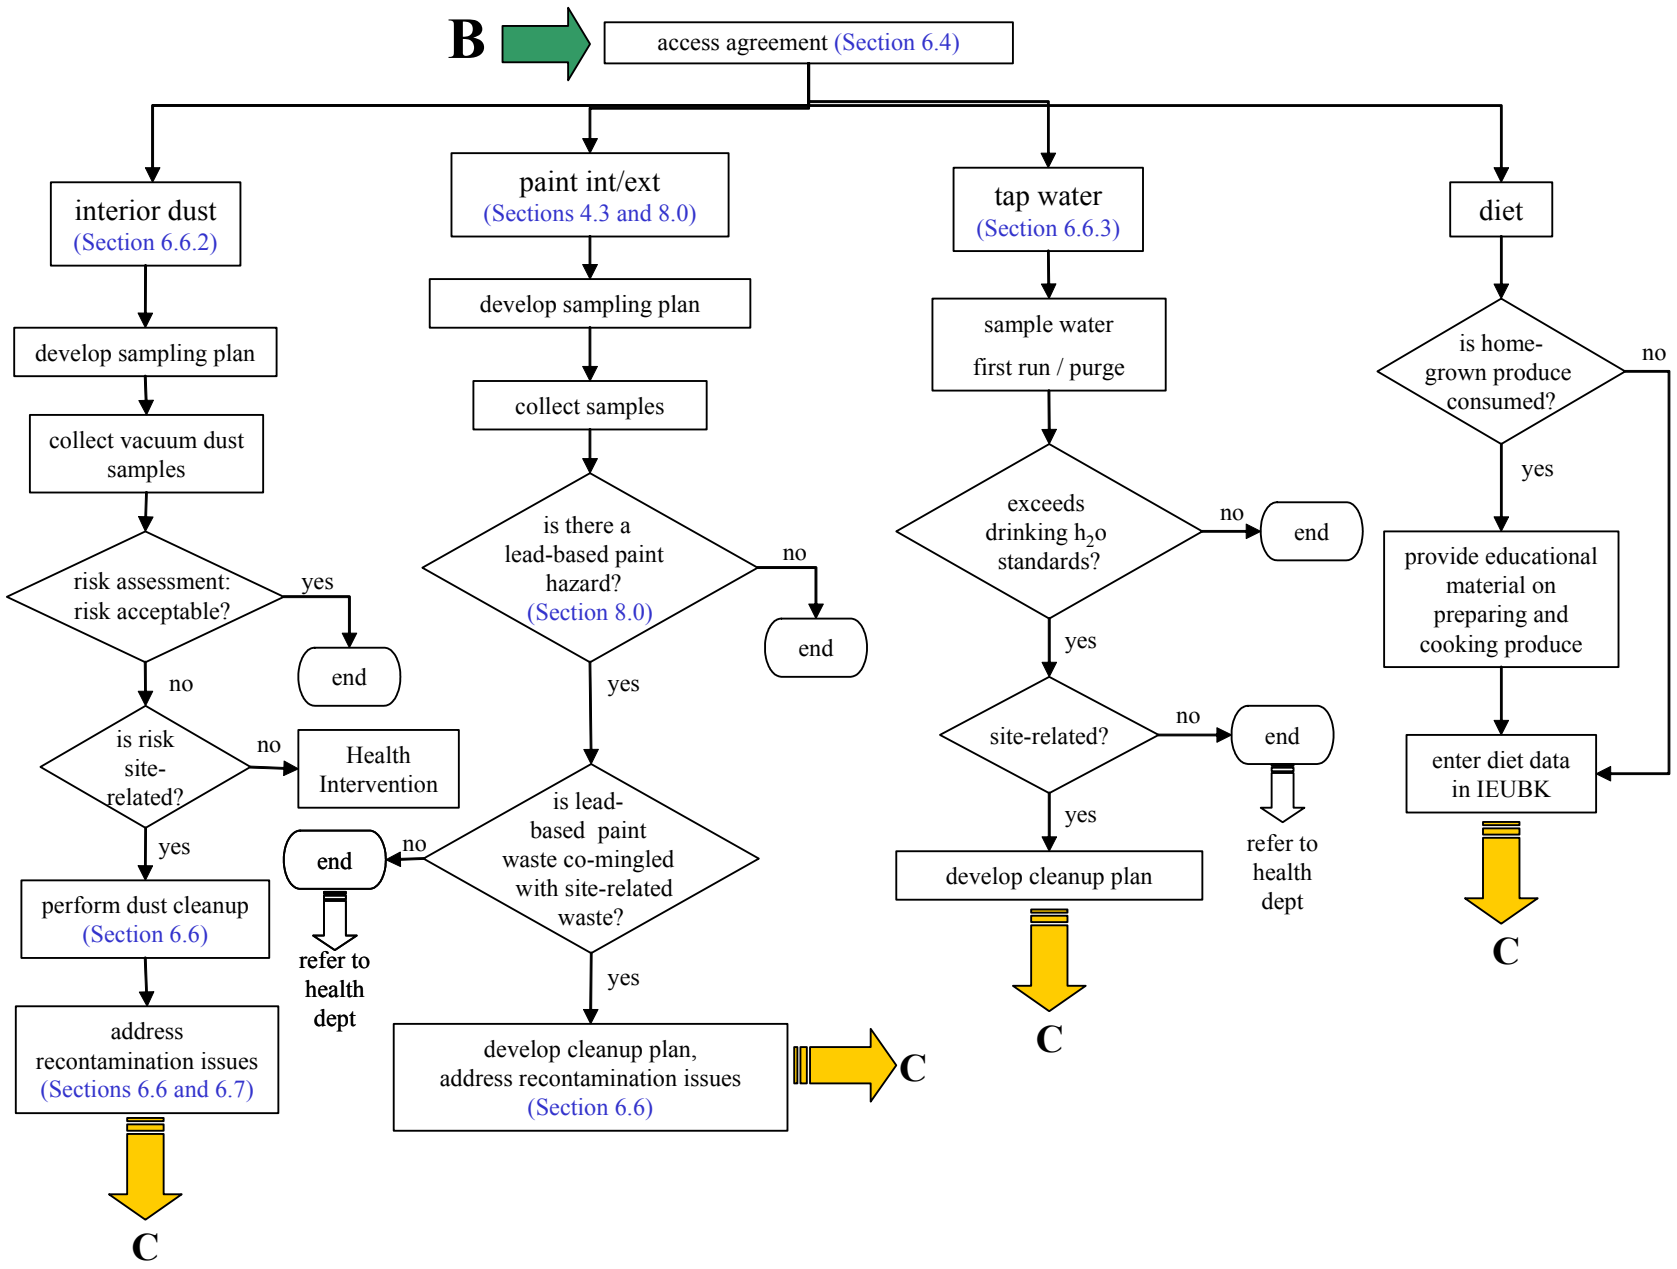

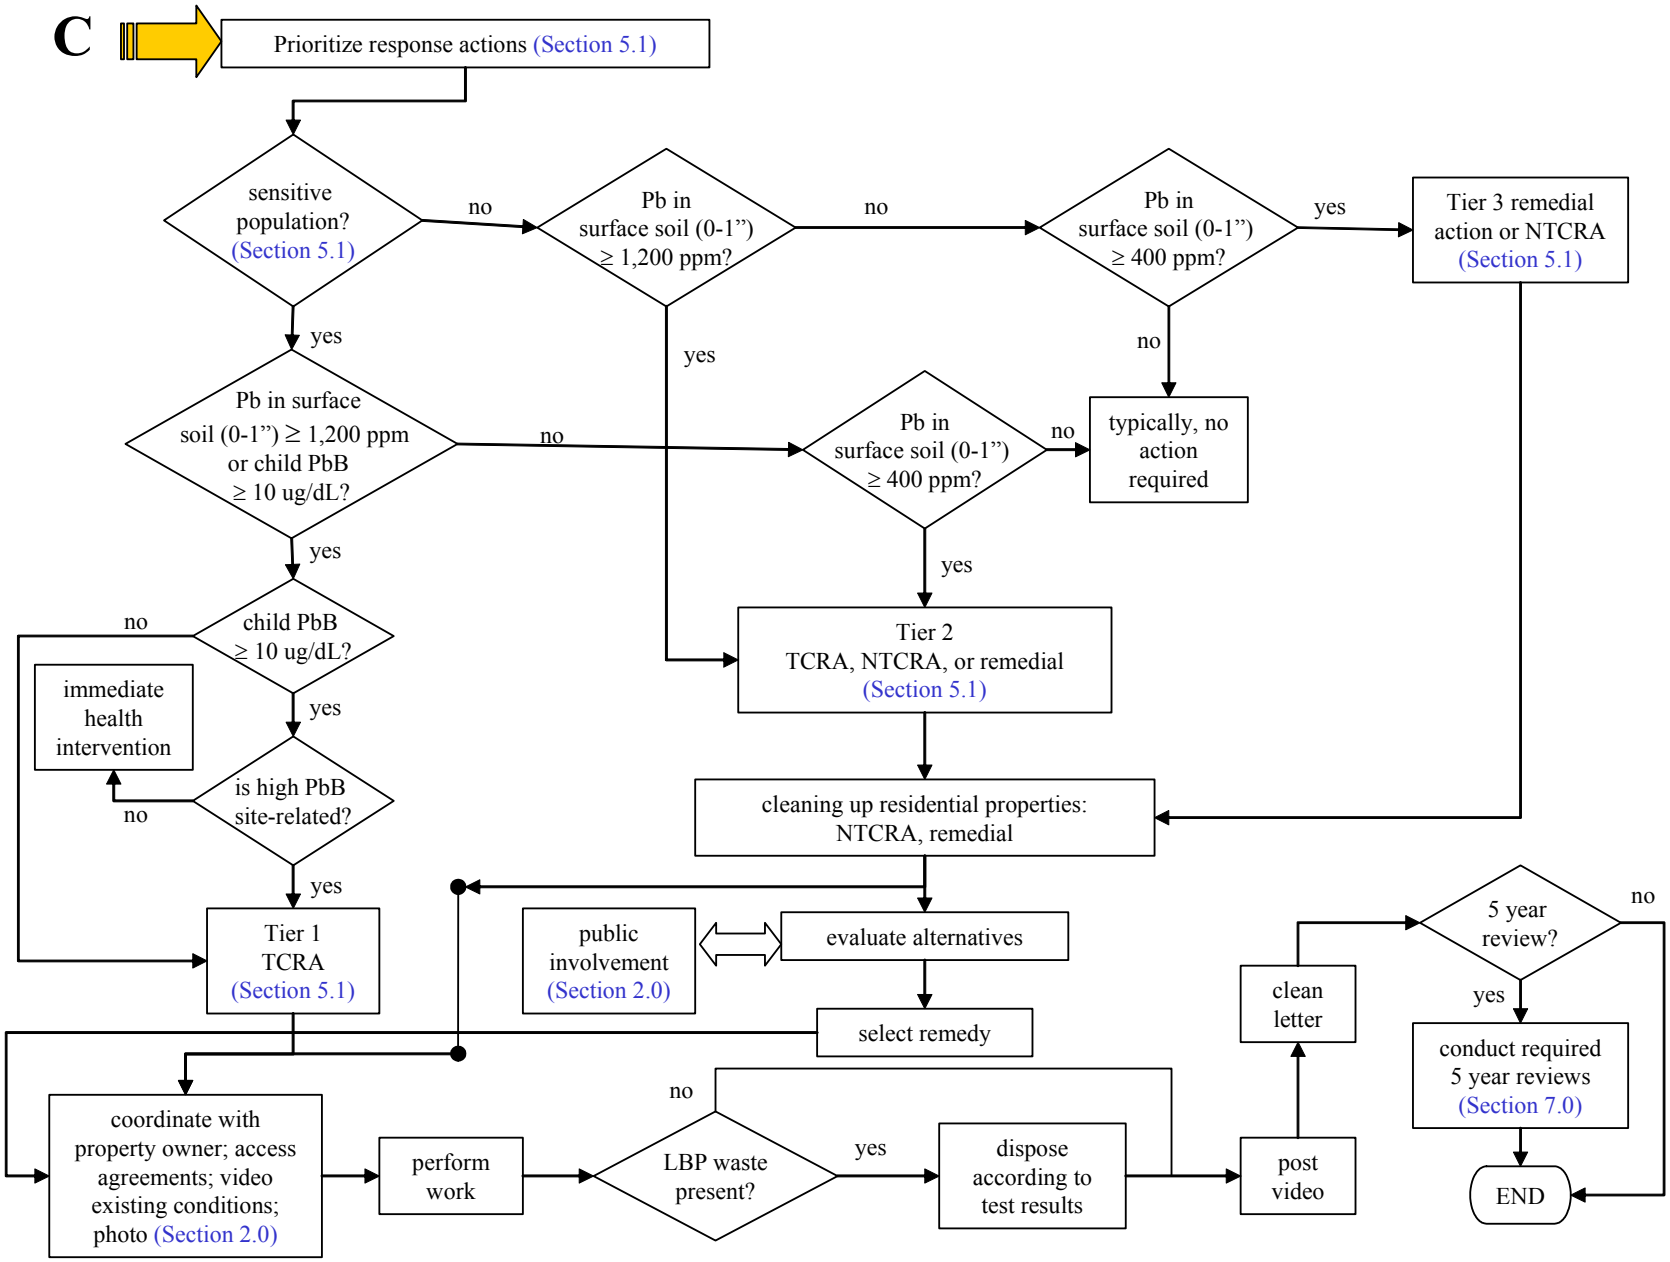

Figure 5-1. (continued)

The concentrations that are used to define tiers should not be confused with clean-up numbers, which are based on the PRG determined with the IEUBK model and an analysis that includes the nine criteria listed in the NCP (EPA, 1990b). The 1,200 ppm concentration is not an action level for TCRAs, but is intended to provide an alternative to running the IEUBK model if the project manager believes the site poses an urgent threat (EPA, 1997b, 1997c). Certainly, a TCRA could be justified above or below this concentration depending on the conditions at the site. The tiers, for the purposes of this guidance, are defined below (see also Figure 5-1). (Please note the Agency is considering developing new guidance for removal actions.)

- Tier 1 properties have both sensitive populations (children up to 7 years old or pregnant women) and soil concentrations in the surface soils (0–1" depth) at or above 1,200 ppm (EPA, 1997b, 1997c). Also, Tier 1 sites can be identified based upon a demonstration of children's blood lead levels at or above 10 µg/dL. Generally, TCRAs would be taken at Tier 1 properties.

- Tier 2 properties have either sensitive populations and soil lead concentrations in surface soils between 400 ppm and 1,200 ppm, or no sensitive populations and surface soil lead concentrations above 1,200 ppm, but not both. Tier 2 properties can be addressed through TCRAs, or non-time-critical removal actions (NTCRAs), or long-term remedial actions.

- Tier 3 properties have surface soil concentrations below 1,200 ppm, but above 400 ppm, and no sensitive populations present. Tier 3 sites would typically be addressed through long-term remedial actions or NTCRAs.

Tier 1 should be the highest priority for immediate action and Tier 3 should be the lowest priority for immediate action. Residential properties can move into a different tier if conditions change (e.g., small children or pregnant women move into a house). A typical residential lead site will contain a combination of properties that fit into different tiers. The project manager should use judgement to determine whether or not to perform a complete cleanup of contaminated residential properties (as defined in Section 1.3).

As discussed below, remedial actions for residential lead sites should use the IEUBK model. The IEUBK model should be used to assess risks posed by contaminated soils and to determine PRGs for soils at residential lead sites. In order to facilitate TCRAs, a demonstration of elevated blood lead levels or elevated soil-lead levels at or above 1,200 ppm will usually be sufficient. If elevated blood lead levels are the basis for concern, occupational contributions of lead, elevated lead levels in drinking water, lead from LBP, and lead dust in the homes of children or adults with elevated blood lead should be investigated first because these sources of lead can be significant (Appendix B). At this stage, consultation with Regional

risk assessors and public health officials (such as ATSDR) to better understand health impacts is encouraged.

The Agency plans on publishing a future lead removal directive which includes further information on site-tier approaches.

5.2 LONG-TERM REMEDIAL ACTION

The 1994 Office of Solid Waste and Emergency Response (OSWER) Directive 9355.4-12 states OSWER's risk reduction goal for residential lead sites: "... generally, OSWER will attempt to limit exposure to soil lead levels such that a typical (or hypothetical) child or group of similarly exposed children would have an estimated risk of no more than 5% exceeding the 10 : g lead/dL blood lead level." (P_{10}<5%) (EPA, 1994b). It is important to note that this recommendation (i.e., P_{10}<5%) is meant to apply to a single residential property or another discrete exposure area, not on an area- or community-wide basis (i.e., 5 children out of every 100 actually exceed 10 : g/dL). It is also important to note that selecting a soil lead concentration in this manner will not guarantee that a given child will not exceed a blood lead level of 10 : g/dL. Many factors other than soil concentration cause variance in blood lead levels: pica behavior, or other sources of lead not included in the exposure unit, such as paint, diet, etc. (e.g., this could include soil at a camping site or other remote site frequented by the child).

The 1998 OSWER Directive 9200.4-27P ('Clarification') (EPA, 1998a) recommends that the IEUBK Model be used as the primary tool to generate risk-based soil clean-up levels at lead sites for current and future residential use (Appendix B). Additionally, the 1998 Clarification states that response actions can be taken using IEUBK predictions alone, and that blood lead studies, while providing useful information, should not be used for establishing long-term remedial or non-time-critical removal clean-up levels at lead sites. Regarding exposure units at residential lead sites, the 1998 Clarification states: "... it is recommended that risk assessments conducted at lead-contaminated residential sites use the individual residence as the primary exposure unit of concern" (EPA, 1998a; Appendix B). This document clarifies the definition of exposure unit provided in the 1998 Clarification. In addition to the individual residence, accessible site-related lead sources outside the residential setting should also be evaluated to understand how these other potential exposures contribute to the overall risk to children. When the evaluation indicates a significant contribution to risk, clean-up measures should be determined for those areas.

Empirical blood lead data occasionally deviates significantly from IEUBK Model predictions. This can be due to numerous factors, including the implementation of lead exposure-reduction and health education programs, and uncertainties in the exposure parameters of the Model as well as uncertainties in the blood lead data (Mushak, 1998). Regarding this issue, the 1998 Clarification states: "Where actual

blood lead data varies significantly from IEUBK Model predictions, the model parameters should not automatically be changed. In such a case, the issue should be raised to the TRW to further identify the source of those differences" (Appendix B). Basically, model inputs should be changed only when defensible, site-specific information that is specifically applicable to the parameters is collected. Moreover, these changes should also ensure that model outputs are protective of future residents. Examples of such information are dust lead concentration, drinking water concentration, bioavailability data (e.g., *in vivo* pig studies), and soil-to-dust ratio. The predictive capacity of the IEUBK Model depends upon the representativeness of the inputs. Section 4 discusses the collection of the data used to estimate some of these inputs.

In summary, there is no national clean-up standard for lead in residential soil on a Superfund site; however, there is a consistent process by which residential soil lead clean-up levels are selected. One step is to gather site-specific data as recommended in Section 4 of this Handbook and review other guidance on the use of the IEUBK Model (EPA, 1994b; TRW web site: http://www.epa.gov/superfund/programs/lead/ieubk.htm). Risk assessors (and other data users) should be consulted early to assist with data collection and planning (EPA, 2000d). Another step is to get assistance from the regional risk assessor(s) to run the IEUBK Model with applicable site-specific inputs. Running the model should allow the determination of a site-specific PRG that corresponds to a P_{10} for a typical child, or group of similarly exposed children, that is no more than 5%. Another step is to select a site-specific residential soil lead clean-up level that is based on the model-derived soil lead PRG and an analysis of the nine criteria consistent with the NCP (Superfund sites only) (EPA, 1990b). If the proposed clean-up level is outside of the range of 400 ppm to 1,200 ppm lead, then the draft decision document for the site is sent to the Lead Sites Consultation Group (LSCG) for review (EPA, 1997b).

Lead Sites Consultation Group (LSCG) – The Lead Sites Consultation Group (LSCG) was created in 1997 to promote national consistency in decision-making at lead sites across the country (EPA, 1997b). The main purpose of the group is to review key response decisions at lead sites. The LSCG is comprised of senior management representatives from the Waste Management Divisions in all 10 EPA regions along with senior representatives from the Office of Emergency and Remedial Response in EPA headquarters.

The LSCG is supported by EPA's Technical Review Workgroup for Lead (TRW) and the national Lead Sites Workgroup (LSW). According to Agency policy, there are three triggers that cause the review of lead-related proposed plans by the LSCG (EPA, 1997b):

1) Residential contaminated lead sites with proposed cleanup levels outside a 400 to 1,200 ppm soil-lead level;
2) Sites that envision actions to address non-soil lead-contaminated media;
3) Routine LSW deliberations that identify a unique or precedent setting site issue(s).

6.0 APPLICATION OF CLEAN-UP NUMBERS/REMEDIATION

The following section provides a detailed discussion of recommended minimum considerations to remediate residential soil and other sources of lead in residential settings. The guidelines stated below apply to early/interim actions and long-term remedial actions. However, due to statutory funding limitations that apply to time-critical removal actions, site-specific determinations regarding yard size limitations, and whether to clean up empty lots and other sources of lead (paint, dust, tap water), should be made by the project manager on a site-by-site basis.

6.1 MINIMUM EXCAVATION DEPTH/SOIL COVER THICKNESS

Based on Agency experience, it is strongly recommended that a minimum of twelve (12) inches of clean soil be used to establish an adequate barrier from contaminated soil in a residential yard for the protection of human health. Cover soil can either be placed after excavation as backfill or placed on top of the contaminated yard soil. The rationale for establishing a minimum cover thickness of 12 inches is that the top 12 inches of soil in a residential yard can be considered to be available for direct human contact. With the exception of gardening, the typical activities of children and adults in residential properties do not extend below a 12-inch depth. Thus, placement of a barrier of at least 12 inches of clean soil will generally prevent direct human contact and exposure to contaminated soil left at depth.

Removal of lead-contaminated soil to depths greater than 12 inches should be considered at sites in cold regions with non-soil lead-contamination sources, such as tailings and crushed battery casings, and whenever it is cost-effective. The additional response cost should be compared to future IC and monitoring costs associated with leaving the material in place. Full vertical removal of residential soil has many advantages, such as reducing or avoiding the costs of maintaining the soil cover, the placement of subsurface barriers/markers, and obtaining environmental easements. Full removal of contaminated soil also satisfies EPA's preference for permanent remedies and normally allows the remediated yard to return to unrestricted use.

Twenty-four (24) inches of clean soil cover is generally considered to be adequate for gardening areas; however, site specific conditions that may require more soil cover (e.g., presence of burrowing animals) should be considered. A 24-inch barrier normally is necessary to prevent contact of contaminated soil at depth with plant roots, root vegetables, and clean soil that is mixed via deep rototilling. Raised garden beds may be built to obtain 24 inches of clean soil, and may be more cost effective than excavating to 24 inches in depth, e.g., excavate 12 inches of contaminated soil, then add 24 inches of soil to create a 12" raised bed.

6.2 SOIL CLEAN-UP OPTIONS

Currently, there are only two remedial actions that generally are considered to be protective, long-term (not interim) remedial actions at residential properties: (1) excavation of contaminated soil followed by the placement of a soil cover barrier and (2) placement of a soil cover barrier without any excavation of contaminated soils. Excavation followed by the placement of a soil cover is the preferred method and is strongly recommended at sites with relatively shallow contamination, such as many smelter sites. In most cases, excavation and placement of a soil cover should be performed whenever the specific conditions of a site do not preclude it. For example, it may not be feasible to fully excavate a very large site cost-effectively, therefore capping, also considered to be protective, may be more appropriate. The advantage of the preferred method is that it is a permanent remedy in terms of removal of lead from areas where children may be exposed.

Several treatment technologies are currently under development to reduce the bioavailability of soil lead, but have not yet been proven to be protective in the long-term. These include amending the soil with phosphorus or high iron biosolids composts. Preliminary results have shown phosphate treatment to reduce the bioavailability of lead in soil by as much as 50 percent. This would mean that soil with lead concentrations in the range between clean-up levels calculated with the pre- and post-treatment bioavailability values could be treated instead of removed (e.g., if the IEUBK model-derived clean-up number using the pre-treatment bioavailability were 400 ppm lead, and the calculated post-treatment clean-up level were 800 ppm lead, then the yards with lead concentrations between 400 ppm and 800 ppm could be treated rather than excavated or capped).

Over time, the efficacy of the phosphorous treatments appears to increase. This is consistent with what is predicted using thermodynamics. To date, the treatability studies have been monitored for 3–5 years. Additional monitoring will be necessary to assure the long-term stability of the observed reduction in bioavailability.

Some other existing technologies for soil remediation that are not currently considered acceptable for residential lead cleanups are rototilling, phytoremediation, and interim controls, such as mulching, seeding, and sodding (without prior removal of contaminated soil). Rototilling is not considered a permanent, protective remedy in that no lead removal occurs, and adequate mixing of soil is difficult, if not impossible, to achieve; additionally, rototilling may increase the volume of soil, which ultimately requires remediation. Mulch, sod, or other vegetative covers are generally not considered permanent, protective remedies in that no lead removal occurs, and there is no guarantee that grass, mulch, or other vegetative cover will be maintained in good condition over time.

Additionally, land use changes that may occur within a yard, such as starting a garden or putting in a swing set, are not precluded in any way by mulch, sod, or other vegetative cover. Lastly, phytoremediation is not currently an appropriate technology for residential lead cleanups due to several factors: (1) the lead concentrations at many residential sites are not within the optimal performance range for the plants; (2) the plants may concentrate lower level lead contamination and present an increased disposal cost if the plants fail the TCLP test, but the unremediated yard soil does not fail; (3) the length of time required for remediation; (4) the potential conflicts with local regulations pertaining to yard maintenance; and (5) the depth of remediation achieved may be inadequate.

6.3 INTERPRETING SAMPLING RESULTS

Based upon the results of the sampling efforts (Section 4.0), this section describes the implementation of two clean-up options: (1) excavation and backfill (and placement of a visible barrier if applicable); or (2) soil cover placement (and placement of a visible barrier if applicable). The options should be performed as described below (see also Figure 6-1). The goal should be to remove all contaminated soil or provide a minimum 12" clean soil barrier. The following describes the implementation of option 1:

- If the 0–1" horizon exceeds the clean-up level, a 6 or 12" excavation is recommended, depending on the 6–12" sample horizon results;
- If the 1–6" or 0–6" horizon exceeds the clean-up level, a 6 or 12" excavation is recommended, depending on the 6–12" sample horizon results;
- If the 6–12" horizon exceeds the clean-up level, a 12" excavation is recommended. A visual barrier is required if the 12–18" horizon exceeds the clean-up level;
- If the 0–1, 0–6 or 1–6" horizons exceed the clean-up level and the 6–12" horizon does not exceed the clean-up level, a 6" excavation is recommended; a visual barrier is not needed.

	Depth	Soil Concentration Exceed Action Level?							
	0-1”	Yes	Yes	Yes	Yes	No	No	No	No
	1-6” (or 0-6”)	Yes	Yes	No	No	No	Yes	No	Yes
Remedial Action Options	6-12”	Yes	No	Yes	No	No	No	Yes	Yes
Option 1: Excavation (& Backfill)	Depth of excavation	12”	6”	12”	6”	No action	6”	12”	12”
Option 2: Capping	Soil cover thickness	12”	12”	12”	12”	No action	12”	6”	12”

Figure 6-1. Interpreting Sampling Results. The figure suggests remedial actions based on the results of composite soil samples collected for each of the depth intervals shown. The figure includes two remedial action options: (1) excavation followed by backfilling, and (2) placement of a clean soil cover without removal of soil that exceeds the action level. To use the figure, find the column of the table that agrees with the soil sample results for your site, then read down the table to determine the depth of soil to remove (option 1: excavation remedies) or the thickness of the soil cover recommended (option 2: capping remedies). For example, the heavy border around the third column of the table corresponds to a situation where the average lead concentration in the 0–1" and 1–6" depth intervals exceed the action level, but the 6–12" interval does not. In this example, it is recommended to remove the top 6" of contaminated soil and replace it with clean soil, or to place a 12" clean soil cover (cap). The goal is to provide a minimum 12” barrier of clean soil when the underlying soil exceeds the action level. Please refer to Section 6.3 for further explanation.

The following describes the implementation of option 2:

- If the 0–1" horizon exceeds the clean-up level, a 12" soil cover and visual barrier should be used;
- If the 0–6" or 1–6" horizon exceeds the clean-up level, a 12" soil cover and visual barrier should be used;
- If the 6–12" horizon exceeds the clean-up level (but not the 0–1", 1–6", or 0–6" intervals), a 6" soil cover should be used;
- If only the 12–18" horizon exceeds the clean-up level, no capping is needed.

The decision to perform soil cleanup to depths greater than 12 inches should be considered on a site-by-site basis. Some advantages to full vertical soil cleanup are listed in Section 6.1. However, there are many sites where lead contamination is located at depth. Full vertical soil cleanup may not be cost-effective and/or feasible at such sites. The depth of excavation and soil cover thickness is an important factor to be considered during the analysis of the nine criteria per the NCP (for Superfund sites) (EPA, 1990b). Potential for freeze/thaw upward migration, groundwater contamination, and the cost, extent, and effectiveness of ICs are some of the factors to be considered in this analysis.

Sampling results obtained for residential lots may indicate that only a portion of the lot contains soil that exceeds the selected clean-up level. For properties less than 5,000 square feet, the spatial scale for the remedial decision should be one-half of the yard. For properties greater than 5,000 square feet, the property should be divided into four quadrants and a remedial decision should be made for each quadrant. It is usually protective to excavate only the portion(s) of the lot that exceed the clean-up level (Figures 6-2a and 6-2b). However, removal of the sod layer and resodding/reseeding the unexcavated portion(s) of the lot is strongly recommended to promote consistency in the vegetative cover of the yard for homeowner satisfaction. When interpreting sampling results for a property, the sampling results of surrounding properties should also be considered to lessen the probability of mislabeling the property as being below the clean-up level, when it is actually above, and to avoid “patchwork clean-up” patterns, which are prone to recontamination.

If the only portion of the yard that exceeds the selected clean-up level is the drip zone, the exterior paint should be checked for lead content. If the drip zone contamination does not appear to be paint-related, the drip zone should generally be cleaned up. If the drip zone contamination appears to be solely paint-related, EPA should promote the remediation of the exterior LBP by local health agencies, other local government agencies, state health agencies, and/or the homeowner. At a minimum, the resident should be notified and informed of the disclosure requirements (Appendix A). Consideration should be given to also notifying the relevant local government agencies and informing them about available remedies, such as HUD grants.

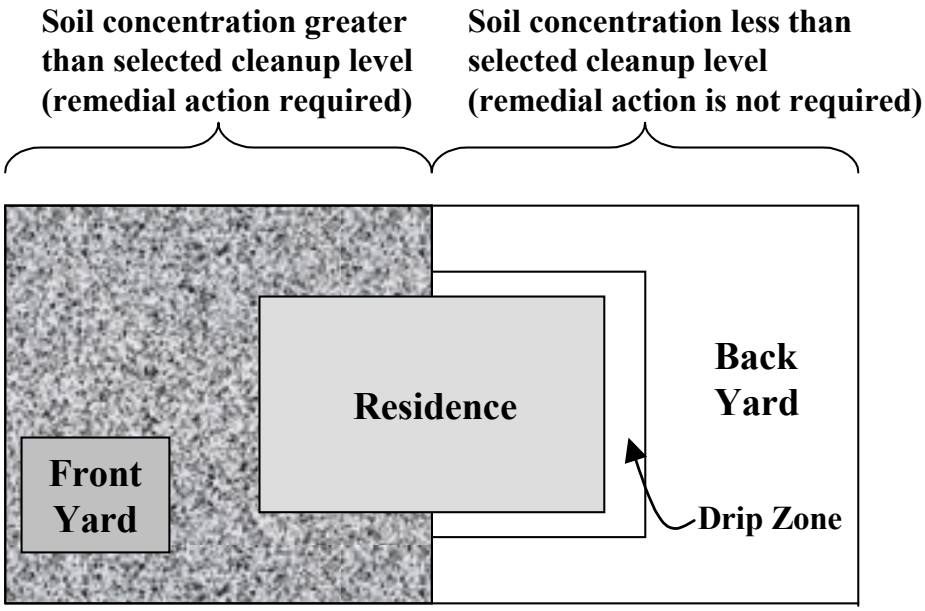

Figure 6-2a. Partial cleanup of residential lot less than or equal to 5,000 square feet in size. In this example, the lead concentration measured in the front yard exceeds the selected clean-up level while the concentration measured in the backyard does not. Cleanup may be limited to the front yard although it is recommended that the sod layer in the entire lot be removed to promote consistency in the vegetative cover on the property for homeowner satisfaction. The entire drip zone should be cleaned up if the average lead concentration exceeds the clean-up level. For example, in the above figure, the drip zone in the back yard (as well as the front yard) should be cleaned up if the average concentration in the drip zone exceeds the clean-up level. Please refer to Section 6.3 for further explanation.

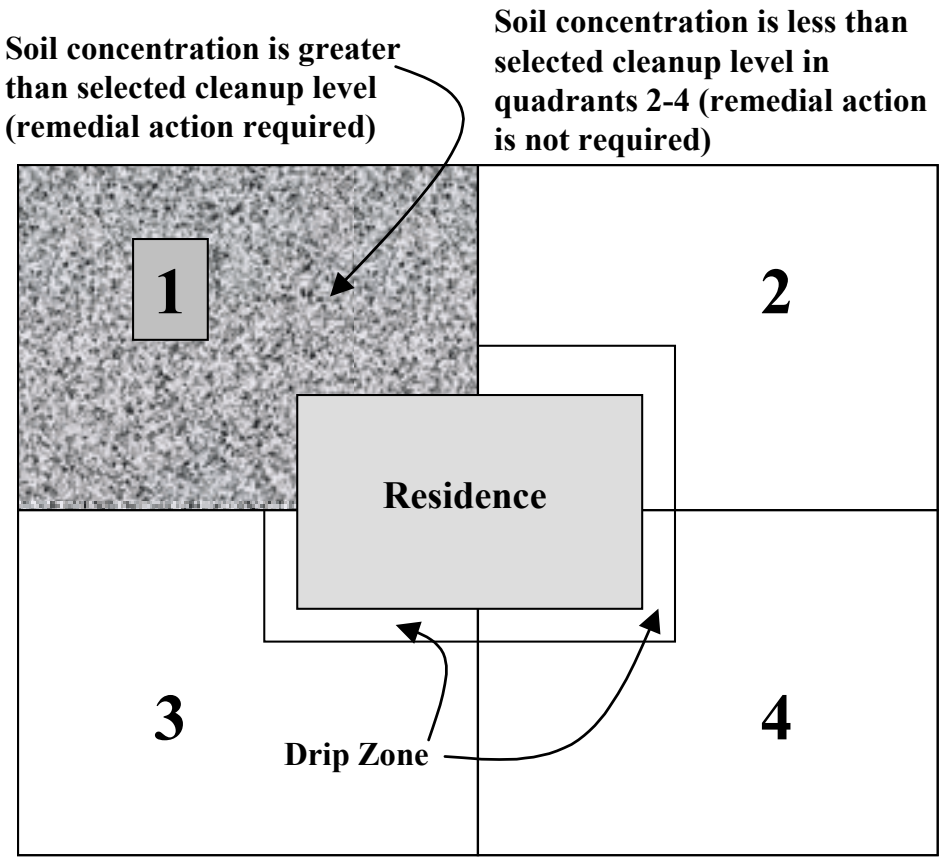

Figure 6-2b. Partial cleanup of residential lot greater than 5,000 square feet in size. In this example, the lead concentration measured in quadrant 1 exceeds the selected clean-up level while the concentration measured in quadrants 2–4 do not. Cleanup may be limited to quadrant 1 although it is recommended that the sod layer in the entire lot be removed to promote consistency in the vegetative cover on the property for homeowner satisfaction. The entire drip zone should be cleaned up if the average lead concentration exceeds the clean-up level. For example, in the above figure, the drip zone in quadrants 2–4 (as well as quadrant 1) should be cleaned up if the average concentration in the drip zone exceeds the clean-up level. Please refer to Section 6.3 for further explanation.

6.4 OTHER CLEANUP CONSIDERATIONS

The area remediated on a single property normally should not exceed one acre. This limitation is based on three factors: (1) typical lot sizes in residential areas throughout the country generally do not exceed one acre; (2) the portion of a property where the majority of exposure to contaminated soil occurs generally does not exceed one acre; and (3) EPA should generally not excavate/cover with soil the entirety of very large yards due to cost-effectiveness considerations.

The goal for cleanup of a yard that exceeds one acre is to excavate or cap the portion of the yard that is in frequent use and continue to limit exposure in the unremediated portion of the yard. To this end, it is recommended that the unremediated portion of such a yard be fenced to clearly delineate the remediated and unremediated areas and to limit the potential for off-site migration of contaminants (e.g., vehicle tracking). Exceptions to this general approach may include areas outside the one-acre area that are used for recreation and gardening, areas with the potential for residential development, and areas in close proximity to other residential areas. As stated in Section 6.5, any unremediated areas of a property should be documented on the clean-up documentation letter for such property, and consideration should be given to implementing ICs for those areas.

If contaminated soil is not removed to the full depth of contamination (i.e., where soil concentration is greater than clean-up level) on a property, a permanent barrier/marker that is permeable, easily visible and not prone to frost heave, should be placed to separate the clean fill from the contamination. This applies to both incomplete vertical excavation with placement of a soil cover and placement of a soil cover without excavating contaminated soil. Selection of an appropriate permanent barrier/marker should be based on the type of contamination left in place, the chemical/physical characteristics of the soil (e.g., pH), the potential for upward migration of the contamination, and/or the types of ICs developed for the site. Examples of suitable barriers/markers include snow fencing (usually orange), a clean, crushed limestone layer, and geofabric.

Empty lots that are zoned residential and contain soils with lead concentrations greater than the clean-up level should be cleaned up when in close proximity to other residential lots. Examples of this are lots between two houses and lots that are near occupied lots. A site-specific determination should be made for these situations. Also, unpaved lots used for vehicle parking should be sampled, and cleaned up if necessary, or access restrictions put in place to prevent recontamination (e.g., vehicle tracking of contaminants) even if no current direct exposure exists. However, it is not the intent of EPA to clean up tracts of remote, undeveloped, lead-contaminated land that may be developed into residential lots in the future. This clean-up responsibility should be borne by the land developer. Institutional controls should

be developed to ensure safe development in these areas, since under CERCLA developers could be held liable for improper cleanup.

6.4.1 Background Lead Concentrations

Many of the “Lead Sites” on the NPL are located in areas with high natural background lead concentration. Often this problem is exacerbated by the presence of high background concentrations of lead in various media (such as soil and groundwater) from anthropogenic sources such as automobile emissions, mining, and smelting (the latter two sources would be considered ‘background’ if they are not associated with the site). It should be noted that CERCLA 104 (a)(3) limits the Agency from taking response actions to address "... naturally occurring substance in its unaltered form, or altered solely through naturally occurring processes or phenomena, from a location where it is naturally found” (EPA, 2000a). Generally, under CERCLA, clean-up levels are not set below natural or anthropogenic background concentrations (EPA, 1996c, 1997d, 2002). Cleanup below natural or anthropogenic background concentrations is normally not performed because it is not cost-effective, it is technically infeasible and there is a high likelihood of recontamination by surrounding areas that have not been remediated (EPA, 2002).

Public education about ubiquitous risks should be incorporated early in the process to help the community understand that Superfund actions are designed to address risks from specific releases to the environment (EPA, 2002). In situations like these, it may be appropriate to examine land uses that limit exposures through implementation of ICs. For more information on this approach, please refer to the 1998 Clarification to the Revised Interim Soil Lead Guidance for CERCLA Sites and RCRA Corrective Action Facilities (Appendix B). Site-specific factors should determine what range of alternatives and what clean-up levels will achieve a protective remedy satisfying the nine criteria specified in the NCP.

Remedial decisions often involve a comprehensive response coordinated with other responsible authorities, such as a local public health district, state departments of environmental protection, housing agencies, and private parties. An effort should be made to identify other programs or regulations that may have the authority and capability of addressing risks associated with high natural or anthropogenic background (EPA, 2002). Additional guidance is available for developing a risk management-based response strategy that is protective of human health and the environment (EPA, 1988).

6.5 YARD CLEANUP SPECIFICS

It is important to define the limits of the properties that will be remediated. The use of property lines rather than temporary features, such as fence lines, to delineate boundaries is recommended. The use of temporary features may result in partial cleanup of some properties.

Whether remediation consists of excavation and placement of soil cover or just the placement of a soil cover, consultation with the property owners is important to the development and implementation of response actions and may necessitate property-specific deviations to the guidelines listed in this section. Flexibility is essential to a successful residential lead clean-up program. Some residents may want to pay for upgrades during the cleanup of their yard, such as paving a driveway after excavation, or to have some yard features removed, such as taking out a damaged patio. Within reasonable limits, such requests should be entertained on a yard-by-yard basis. Granting such requests can greatly contribute to building public trust and satisfaction with the clean-up program. All additional costs associated with special requests and considerations must be borne by the homeowner.

Prior to cleanup of a residential yard, access from the property owner should be obtained; access obtained from tenants or renters is not sufficient. It is recommended that access be obtained by going door-to-door. If residents are not home, a blank access agreement with instructions for signature and submission to EPA, along with relevant contact information should be left at the residence (but not in the mailbox). An example access agreement form is presented on page D-6 of Appendix D. As stated in Section 4.2.1, it is suggested that access for remediation be obtained at the time access for sampling is sought. Examples of combined sampling/remediation access agreements are presented on pages D-4 and D-5. An example of a dust cleanup access agreement form is presented on page E-2 of Appendix E. Many residents may refuse access for dust cleanup while granting access for yard-soil cleanup. Combining dust access agreements with other access agreements is not recommended.

Prior to initiating clean-up activity, the condition of each property should be documented and recorded on videotape. 'Clean-up activity' includes any disturbance of the property, including the removal of debris and dilapidated structures that may be required prior to initiating the excavation of contaminated soil. An example of a property inspection form is provided in Appendix F. EPA should enter into a written agreement with the resident regarding any special requests or considerations in cleaning up the yard, e.g., replacing concrete walkway with brick. All additional costs associated with special requests and considerations must be borne by the homeowner. Any contaminated yard areas that will not be cleaned up, special resident concerns, and any deviations from strict soil excavation or capping should be noted on this agreement.

Other possibilities for cleanup-related agreements include sod/lawn watering agreements. A sod-watering agreement basically allows for payment to residents for watering the sod that is placed by the remediation contractor. A payment is made before watering is required to cover the water bill and some of the time involved. A second payment is made if, at the end of one month, the sod is in good condition. A similar agreement should be established for maintaining lawns that have been initiated by hydroseeding. This can be a useful incentive program that can also save money. The contract with the remediation contractor should require the contractor to establish vegetation on each property, restore the pre-construction drainage patterns on each property, and perform repairs for damages to the property.

Relocation of residents during yard soil remediation is rarely needed and is generally not recommended (EPA, 1999b). (Guidance is available online at: http://www.epa.gov/oerrpage/superfund/tools/topics/relocation/index.htm.)

Specific safety issues during residential yard cleanup, including ingress and egress to the home, should be coordinated with the property owner/residents and spelled out in the Health and Safety Plan.

Incomplete barriers (such as rock or gravel) or minimal use areas (such as areas under porches), which exceed the applicable clean-up level, should be cleaned up to the extent practical. Although removal is preferred, if it is not feasible to clean up the area, a barrier, which effectively limits access, should be constructed. For example, for areas underneath porches, typically the preferred barrier would be shot-crete (sprayed concrete that can easily be placed in tight or confined areas). It may be preferable to place asphalt rather than gravel on heavily-trafficked roads or driveways, especially those that experience severe erosion.

In all cases, every attempt should be made to clean up the entire yard (subject to cost limitations discussed below), however, any residential yard areas without permanent barriers that the resident requests to leave unremediated, such as gardens or patios, should be sampled separately to determine if the selected clean-up level is exceeded. If the clean-up level is exceeded and the owner refuses to allow cleanup of that portion of the yard, then the clean-up documentation letter issued to the owner should note the unremediated area.

The steps of a typical soil cleanup are shown in the text box below.

Steps of a Typical Soil Response Action

Step 1 (Access Agreement) - Collect access agreement(s) from each owner and/or tenant before any work is conducted.

Step 2 (Initial Survey) - Interview the resident(s) to determine if there are any specific problems that need attention, and if there are any structures or property the owner wants to have disposed, stored, or left untouched. The contractor will conduct a thorough documentation of the property using drawings, digital photographs, and videotapes. Once documented, the owner is required to sign a property agreement which documents any special requests or considerations in cleaning up the yard, any contaminated yard areas that will not be cleaned up, provisions for structural concrete and fence restoration, and deviations from strict soil excavation and capping.

Step 3 (Excavation) - Each tract is excavated by the contractor(s), who will also complete documentation and provide depth confirmations.

Step 4 (Backfill) - After excavation of properties where full excavation to depth has been performed, the excavated area is backfilled and compacted. After excavation of properties with a vertical excavation limit, a permanent, permeable barrier/marker is placed in the excavated area. After placement of the barrier/marker, the excavation area is backfilled and compacted.

Step 5 (Restoration) - Restoration of the property, including landscaping, sod/seeding, fencing, and concrete (if needed) is conducted.

Step 6 (Final Inspection) - After restoration activities are complete, the EPA, PRP, or its agent (e.g., Corps of Engineers) will conduct a final inspection.

Step 7 (Closeout Form) - A property closeout form should be signed by the property owner, which documents the owner is satisfied with the remediation of the property. Any outstanding issues between the EPA and the homeowner that have not been fully resolved should be documented in the closeout form.

Step 8 (Clean Letter) - After the homeowner signs at property closeout form, the EPA issues a "clean" letter, which documents the property has been remediated. Any areas that are not cleaned up via the owner's request, such as gardens, should be noted in the "clean" letter. For properties where contamination is not completely removed, the clean letter should also document the presence of contamination at depth, and should describe the protective measures that were taken to prevent exposure to the remaining contamination (i.e., barriers/markers).

6.6 CLEANUP OF OTHER SOURCES OF LEAD

Lead in the environment can originate from many sources. In addition to soil, the main sources to consider when performing clean-up activities are interior and exterior LBP, lead-contaminated interior dust, drinking water, and occupational exposure resulting in subsequent contamination of homes. Generally, sources other than soil, exterior paint, dust, and tap water cannot be remediated by EPA in the course of residential lead cleanups.

Ultimately, the project managers should strive to address any unacceptable lead-exposure risks at the residence. Sampling and the establishment of clean-up mechanisms needed to take action, such as HUD grants for paint abatement, should be completed as early in the remedial process as possible. Even so, it may not be possible to address all sources of lead in the ideal sequence. When this occurs, other measures should be taken to minimize the potential for recontamination (i.e., to protect the remedy). For example, if deteriorating exterior LBP is present, it is recommended that it be removed prior to initiating any soil clean-up activities in the yard.

Due to transport of lead among media, the preferred sequence of lead clean-up activities at a residence with LBP and lead-contaminated soil would be to clean up the paint first, then the yard soil, and then the interior dust. Clean-up activities performed counter to this sequence increase the risk of recontamination. For example, performing a soil cleanup first at a residence with exterior paint problems increases the potential for recontamination of the soil from the exterior paint. Similarly, interior dust can be recontaminated by interior LBP. Exterior sources have been shown to cause recontamination of the interior when cleaned before community-wide yard cleanup is completed (EPA, 2000e). Accordingly, project managers should make every effort to coordinate the sequence of clean-up activities to prevent recontamination.

CERCLA and the NCP limit Superfund authority to address interior LBP (see Section 1.2) (EPA, 1990b). If a mechanism exists for addressing the paint, such as a HUD grant or a Supplemental Environmental Project (SEP), then the timing of the paint encapsulation or abatement activities may not coincide with the soil cleanup. Additionally, residents may be more reluctant to grant access for dust remediation since it is more intrusive. On the other hand, EPA actions taken to address lead in drinking water from site sources usually can be taken independently from any soil, dust, or paint cleanups, and should be done as soon as practical.

> Supplemental Environment Project (SEP) – Environmentally beneficial projects which a defendant/respondent agree to undertake in settlement of an enforcement action, but which the defendant/respondent is not otherwise legally required to perform.

6.6.1 Lead-Based Paint

The 1998 Clarification presents OSWER's policy with respect to remediation of interior paint, exterior paint, interior dust, and lead plumbing. Regarding interior LBP, the 1998 Clarification states:

> "EPA has limited legal authority to use Superfund to address exposure from interior lead-based paint. As a policy matter, OSWER recommends that such exposures not be addressed through actual abatement activities. However, EPA Regions should promote addressing interior paint risks through actions by others, such as HUD, local governments and health authorities, or individual homeowners as a component of an overall site management strategy. Any activities to clean up interior lead-based paint by potentially responsible parties (PRPs) or other parties should not result in an increase of the risk-based soil clean-up levels" (EPA, 1998a; Appendix B).

Regarding exterior LBP, the 1998 Clarification indicates that the Regions should avoid using the Superfund trust money for removing exterior LBP and soil contaminated from LBP. However, Superfund dollars may be used to respond to exterior LBP to prevent recontamination of soils that have been remediated, but only after determining that other funding sources are not available (EPA, 1998a; Appendix B). The 1998 Clarification states: "As with interior lead-based paint abatement, EPA Regions should promote remediation of exterior lead-based paint by others, such as PRPs, local governments, or individual homeowners. Clean-up activities of exterior paint conducted by PRPs or other parties should not result in an increase of the risk-based soil clean-up levels" (EPA, 1998a; Appendix B).

As a practical matter, project managers should inform each resident regarding the presence or absence of LBP in their home, and options for encapsulation and abatement. The local health agency and/or the state health agency should be informed regarding the availability of HUD grants for paint assessment and abatement. Additionally, regarding PRP-funded cleanups, if any penalties are being considered for non-compliance (Section 6.9), consideration should be given to allowing the PRPs to perform a SEP for paint assessment and abatement in lieu of some or all of the penalty amount.

6.6.2 Interior Dust

Lead-contaminated interior dust can be derived from multiple sources, including exterior soil, interior and exterior paint, homeowner hobbies, workplace, and other exterior sources; thus, it may be difficult to differentiate between sources of dust contamination. Household lead dust contamination may be a significant contributor to elevated blood lead levels, especially for younger children (under the age of three), and may need to be evaluated in determining risks and clean-up actions at residential lead sites. However, as pointed out previously, there are limitations on EPA's authority to abate these sources of contamination to the extent they are not related to releases or threatened releases to the environment (Appendix B).

Based on the 1998 Clarification, OSWER recommends that Superfund monies should generally not be used to take CERCLA response actions for addressing residential dust exposures due solely to interior paint or other interior sources. However, Superfund monies can be used to address interior dust if it can be shown to be derived from an exterior pollution source (e.g., air lead concentration caused by lead smelter, mining, or mineral processing). Dust mat sampling, which was done at the Bunker Hill Site in Idaho (EPA, 2000e), is one possible method of lead source identification; speciation, which is costly, is another method. (Dust mats are used to measure dust lead concentration and loading rates in residences and other structures.) Where interior dust is being addressed by other authorities, the recommendations presented here may be helpful to guide the dust cleanup.

If the lead in interior dust is solely derived from interior paint, EPA should promote addressing interior dust risks through the actions of others, such as HUD, state and local governments, PRPs, or individual homeowners, as a component of an overall site management strategy. The overall site strategy, as outlined below, should also consider the proper phasing/sequencing of actions to address the multiple sources of lead risks at residential lead sites, as discussed at the beginning of Section 6.6.

The baseline risk assessment should document the relative contributions of lead uptake from all relevant media including direct soil exposures and secondary exposures to soil in indoor dust. Replacement of defaults with a site-specific value for the interior dust concentration, or the soil-to-dust relationship (M_{sd}), should be justified through the use of high quality, compelling, site-specific data (EPA, 1994b, 1998c). Dust sampling is preferred for risk assessment and remedial decisions, but dust modeling may be needed to develop or refine soil action levels.

Lead-contaminated interior residential dust presents a significant exposure pathway that can readily be addressed. Consequently, significant health benefit is gained by removal of contaminated interior dust as early in clean-up activities as possible. However, exterior contamination sources present a threat of recontamination to interior of residences (EPA, 2000e; TerraGraphics, 2001). Therefore, any interior dust clean-up actions should be periodic throughout the project and should culminate in a final cleaning of all residences exceeding an action level after the exterior sources have been remediated. As a practical matter, risk management and reduction may need a phased strategy as recommended below:

Early-Phase Actions: Public awareness and health education efforts should be initiated immediately. Entry way dust mats should be provided to residents. HEPA-filter vacuum cleaners should be provided for use by residents. If warranted, a program to abate interior lead-contaminated dust in homes with acute levels should be initiated to provide temporary risk reduction.

Establish appropriate public health partnerships with state and local health departments, ATSDR, and HUD as early as practical.

Mid-Phase Actions: The source of the interior dust lead contamination should be identified. Monitoring of the changes in lead-contaminated dust (e.g., lead loading in dust, lead concentration in dust, exterior-to-interior lead transport) should be initiated. The public awareness/health education efforts and availability of HEPA-filter vacuum cleaners for use by residents should be continued. Assistance to remove and dispose of old carpets should be provided to residents after yard cleanup has occurred.

Final-Phase Actions: Once the exterior lead sources that were found to contribute to interior dust have been addressed, the final step should consider the active remediation of interior lead-contaminated dust. Actions may include: removal of carpeting, cleaning heat and ventilation ducts, wet wiping hard surfaces and soft surfaces (furniture, draperies, bedding, clothing, etc.). Most of these actions should be limited to living spaces. Areas such as attics, crawl spaces, and other non-living spaces need not be addressed unless they are shown to be a continued source of contamination to the living areas . It is important for dust remediation to be performed as the last phase in the site clean-up process to minimize the risk of recontamination.

6.6.3 Lead Plumbing/Tap Water

The 1998 Clarification states: “Generally CERCLA does not provide legal authority to respond to risks posed by lead plumbing within residential dwellings. It should be noted that the water utility is responsible for providing clean water to the residences. As with interior dust, OSWER recommends that EPA Regions coordinate with local agencies to establish a health education program to inform residents of the hazards associated with lead plumbing and how to protect themselves by regularly flushing, or preferably, replacing lead pipes. Soil clean-up levels should not be adjusted to account for possible remediation of lead plumbing” (EPA, 1998a; Appendix B).

With regard to tap water, it should be sampled, and lead levels in the purged sample in excess of the maximum contaminant level (MCL) established by the Safe Drinking Water Act should be addressed. In general, lead concentrations in the purged sample greater than a removal action level (RAL) of 30 : g/L should be addressed through TCRAs; concentrations between the MCL and RAL should be addressed through NTCRAs or long-term remedial actions. Actions that could be taken include provision of bottled

water, connection to a municipal water supply, tap filtration, and installation of deep wells (in remote areas and where shallow groundwater is contaminated). Regarding first run exceedance for lead, the homeowners should be notified that they may need to address a plumbing or corrosion problem, which is outside of the scope of Superfund.

6.7 PREVENTION OF RECONTAMINATION

Project managers should take steps to mitigate recontamination. During site closeout and five-year reviews, the project manager should also check for recontamination at levels which may threaten the remedy.

At many large-area lead sites, cleanup occurs over a long period of time and through multiple phases, throughout which the potential for recontamination exists. During each of these phases, windblown dust sources, vehicle tracking, flooding, and other mechanisms can recontaminate previously cleaned areas. Although best management practices (BMPs) should minimize the movement of contaminated material from each residence being cleaned, vehicle tracking of contamination from areas yet to be cleaned up can significantly raise concentrations of contaminants in cleaned areas. During the early phase, typically an emergency response action, cleanup is focused towards Tier 1 properties, and cleanup favors a "hop scotch" approach to address the worst risks first. This method of remediation can result in recontamination of clean properties. Confirmation samples should be collected in any areas that have been potentially recontaminated.

Another aspect of large-area lead sites is that complete cleanup of residential properties does not always take place for a variety of reasons (see Sections 6.2 and 6.4); instead a barrier or soil cover is put in place over contaminated soils. Flooding can pose a serious problem for these areas in that flood waters can erode away clean materials leaving subsurface contamination exposed, and entrained sediments bearing contamination may be left on top of newly remediated properties. Inadequate drainage of runoff can move lead into cleaned areas (e.g., lead particles on a crowned road with no curb and gutter may be rinsed onto adjacent residential properties with normal rainfall). Additionally, the activities of burrowing animals can bring contaminated soils to the surface.

Best Management Practice (BMP) – In general, BMPs are a combination of practices that are determined to be the most effective and practicable means of controlling point and nonpoint pollutants at levels compatible with environmental quality goals. In this document, BMPs specifically refer to measures taken during construction activities on properties where contamination has been left at depth to prevent the transfer of those contaminants to other media.

Recontamination of clean soil cover can be caused by ongoing homeowner projects, such as digging a hole through a clean barrier to install fence posts or a new tree or shrub, if preventative measures are not taken. Education and licensing of contractors who work on clean barriers/markers should generally be required (e.g., as part of a local ordinance) to ensure the longevity of the remedy. Also, at many sites (e.g., Bunker Hill), ICs have been most effective when linked to the "call before you dig" program typically operated by many counties to avoid disruption of utility service. In addition, large scale residential development projects that may raze old housing in favor of new will frequently recontaminate areas where lead-contaminated soil was left at depth, without appropriate BMPs in place. BMPs include silt fences, hay bales, etc., to limit movement of contamination off a project site, and stockpiling of contaminated soil on a tarp to prevent contamination of underlying soil (Figure 6-3). EPA provides guidance on the implementation of BMPs in construction activities at sites where contamination is present (EPA, 1997e). Best management practices typically add about 5 percent to project cost (TerraGraphics, 2000). Periodic inspections of residential areas should be performed by the local government to ensure that projects within the site are implementing BMPs.

Wind blown dust can pose a significant threat to the health of individuals at a site and can cause recontamination. Tailings impoundments that have dried can be large sources of windblown lead dust. Most tailings impoundments are large; a wind sweeping across the face of one can carry substantial amounts of contaminated dust and then deposit these particles on a downwind residential area, both causing increased exposure to contaminants, and recontaminating clean areas. Wind blown dust sources are typically a key issue to be addressed early in the sequencing of site activities to minimize this migration.

These are but a few examples of how recontamination can be an ongoing problem that needs to be considered at every site during each phase of cleanup. Although mechanisms vary from site to site, the types of response actions put in place and the sequence in which these actions take place can play a significant role in enhancing the permanence and effectiveness of a remedy.

A disposal area may be needed to dispose of contaminated soil from the site to support typical homeowner projects, as some municipal landfills may not accept contaminated soil. Without free or low cost disposal for contaminated soil available to each homeowner and renter, improper disposal is more likely, which would result in recontamination. In addition, a disposal area may be needed if certain materials at a site, such as carpets, fail TCLP and cannot be commingled with solid waste. It may even be appropriate for the remedy to provide free removal of contaminated soil and provision of clean soil to homeowners (but contractors may be required to pay for these services, or obtain material from approved sources) to encourage maximum compliance and further ensure the longevity of the remedy. The

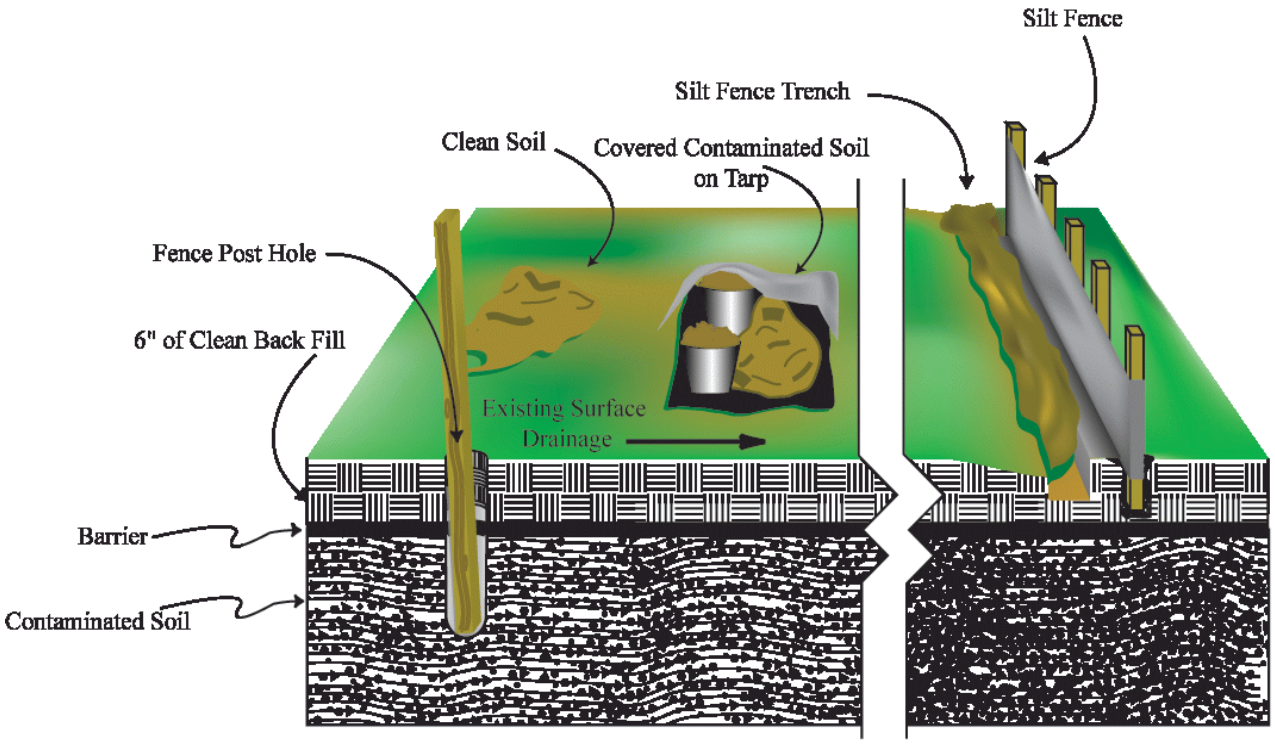

Figure 6-3. Implementing Best Management Practices (BMPs) during construction work. The best management practices (BMPs) shown in the above figure (e.g., a clean soil barrier) represent one component of the ICs which may be put in place by local ordinance to ensure the long-term protectiveness of the remedy and to prevent recontamination. The purpose of BMPs is to minimize the potential for accidental exposure of humans during construction and maintenance activities on sites where wastes have been left in place. The staging of contaminated soil on tarps and/or in small buckets, and the installation of silt fences downgradient of the construction area are examples of BMPs intended to prevent the migration of contaminated material from the construction site. Please refer to Section 6.7.3 for further explanation.

maximum concentration of lead (and perhaps other constituents) allowed in "clean" soil, and the required sampling frequency, should be specified in an IC.

Over the long term, cleanups may not be possible at every property at the same time. A trust fund should be established for the site for the cleanup of properties that are deferred for various reasons, which should be implemented by the local government. In this manner, changes in property ownership over time may be more closely monitored to determine when cleanup at deferred properties might be appropriate (see Section 6.9). Local implementation of the trust fund will ensure that cleanup of these properties occurs as soon as possible, further ensuring the protectiveness of the remedy, further ensuring the protectiveness of the remedy by minimizing the potential for recontamination to the extent possible.

6.7.1 Early Actions

Early response actions (including cleanups for sensitive subpopulations) can be an essential aspect of the response action at a site, as discussed above. These actions should be conducted simultaneously with source area control. The following are considerations that may reduce the potential for recontamination when scoping an early action.

C Seek permanence in selecting the clean-up alternative(s), if possible, such as complete removal to depth of soil contamination at properties where there is an acute risk.

C Consider cleanup of adjacent properties simultaneously that may threaten the permanence or effectiveness of the early action.

C Control fugitive dust sources, access, tracking, and erosion of contaminants to the extent possible.

C Perform HEPA street sweeping to minimize tracking of contaminants throughout a community.

C Evaluate the feasibility of conducting the cleanup of residential areas in their entirety during the early removal phase if contamination is widespread. If this is not possible, limit the early removal actions to immediate risks (Tier 1 and Tier 2 residential properties, including residences with elevated blood lead levels) in order to minimize the potential area where recontamination might occur.

C Provide informational fact sheets to homeowners on how to minimize recontamination on their property.

C Establish an IC to manage cleaned areas. This could involve local and state government agencies, and PRPs that are available to recommend best management practices for homeowner projects and provide education to the homeowner, as well as utility districts and companies likely to breach the barriers/markers put in place.

C Provide site plans or other documentation of areas that have been cleaned up, as well as information on areas that are still contaminated, to the local governmental entity responsible for the maintenance of the remedy, i.e., for monitoring ICs and for tracking properties over time.

• Establish a geographic information system (GIS) for monitoring ICs and properties.

6.7.2 Long-term Remedial Action

Some or all of the following measures may be useful to address the risk of recontamination during the remedial action (Tiers 2 and 3, if a tiered approach is used) and post-design phase:

- Evaluate the permanence and effectiveness of the various remedial actions under consideration. Consider the economic feasibility of complete contaminated soil removal to minimize reliance on ICs.

- Conduct a cost analysis comparing the cost of long term ICs to those of complete removal (EPA, 2000f). For example, property depreciation, tax base impact, additional procedures/cost of utility work, flooding complications/costs, and long term IC administration cost should be taken into account when comparing the cost of a partial removal of contaminants to a complete removal. Property depreciation, while possibly subtle for each property, may add up to substantial losses for the entire community in reference to a county tax base. Also, losses for an individual property over a lifetime of sales could add up to a significant cost. Following cleanup, increases in property valuation from source removal or drainage/infrastructure enhancements (and savings/in-kind services to municipalities) should be considered.

- Remedial action should strive to remediate the contamination in the community by segregable areas, such as a town, or a divisible segment of town. Each segregable area should be cleaned up as quickly as possible (e.g., within one construction season) to minimize recontamination of cleaned properties and to compound the protection to human health (EPA, 2000e). Each community should be cleaned up block by block within these segregable areas, utilizing BMPs to mitigate tracking of contaminants. Site experience suggests that cleanup of up to 800 properties per site per year is possible.

- Fugitive dust that may be a source for recontamination, and access to such sources should be controlled. Air monitoring along with depositional modeling may be necessary to determine if windblown dust presents a significant threat of recontamination. Significant sources of windblown dust should be controlled prior to or simultaneously with cleanup of adjacent residential areas. Consider HEPA street sweeping during remediation and immediately following completion of cleanup to minimize tracking of contaminants throughout a community.

- Complete removal of contaminants should be considered in flood prone areas or areas with a high groundwater level due to the inherent difficulty in maintaining a soil cover remedy in a flood prone area. Drainage-ways containing contamination within their 100-year floodplain, which are

not addressed in the remedy could also lead to remedy failure if the contaminants are eroded to other areas.

C Remediation of contaminated rights-of-way should occur within segregable areas simultaneously, if possible, or as close together in time as possible to minimize vehicle tracking and recontamination of driveways from the rights-of-way.

C Control measures for all remaining sources, such as mining waste piles surrounding the community, should be developed to ensure the remediated neighborhoods are kept clean. ICs should be established to ensure the control, or proper use and disposal of any wastes remaining on site.

C If the residential remedy includes replacement of soils, removal of deteriorating exterior LBP (e.g., by pressure washing) should be considered to minimize the soil recontamination potential.

• Other sources of residential property recontamination should also be considered. For example, homeowners may bring in contaminated soil for fill or other uses on their property.

C Establish permanent funding for ICs. Unless all contaminants are removed, some level of ICs may be necessary. Early establishment of a program is the key to success of a remedy that consists of a partial removal of contaminants.

6.7.3 Institutional Controls (ICs)

EPA defines ICs as administrative and/or legal mechanisms that: (1) help minimize the potential for human exposure to contamination, and (2) protect the integrity of the remedy. ICs accomplish these objectives by directly limiting land or resource use, and/or by providing information that modifies behavior. ICs are used throughout the remedy pipeline, including (1) when contamination is first discovered (i.e., prohibition of excavation of newly discovered soil contamination), (2) when the remedy is ongoing (i.e., restrictions on property use until clean-up levels are met), and (3) when hazardous substances, pollutants, or contaminants remain at the site above levels that allow for unlimited use and unrestricted exposure.

At sites where minimizing exposure is the primary purpose of the IC, it is EPA's policy that if a site cannot support "unlimited use and unrestricted exposure" (EPA, 2000f), ICs are generally required. The "unlimited use and unrestricted exposure" threshold is a site-specific determination similar to that of a five-year review. Essentially, if contamination could result in an unacceptable exposure, ICs would be

required. This is often the case at lead cleanups because residual contamination is frequently managed onsite. Note that the term "residential" is often used interchangeably with the "unlimited use and unrestricted exposure" threshold but these are not synonymous terms. For example, a lead cleanup where the top layer of soil has been removed and replaced can result in a residential use at a site that includes restrictions (e.g., restrictions on digging, requirements for elevated gardens, and an information/outreach program, etc.).

The second common purpose of an IC is to protect the integrity of a remedy. In the lead clean-up context this may mean using institutional controls to prevent penetration of a cap or damage to monitoring equipment. An important consideration in this context is what type of IC will provide the required remedy protection. For example, the primary concern for protecting a remedy in a lead clean-up scenario is typically uncontrolled excavation. For this reason it is important to select ICs that will be relevant to excavators. Examples of potentially effective ICs are local digging or drilling permits and "One-Call" or "Miss Utility" systems. Examples of potentially ineffective ICs are deed notices, because excavators seldom check land records prior to digging.

To better understand the correct IC approach, it is important to understand what tools are available. In general, there are four categories of ICs commonly used in cleanups: governmental controls, proprietary controls, enforcement and permit tools with IC components, and informational devices. The definitions provided below were taken in large part from the current EPA guidance (EPA, 2000f).

Governmental controls are usually implemented and enforced by a state or local government. Some of the more common examples include things like zoning restrictions, building/excavation permits, groundwater drilling and use permits, ordinances, or other provisions that restrict land or resource use at a site. These types of mechanisms are popular in remedies because the administrative processes are in place and are typically well understood within a particular jurisdiction. The greatest concern with this type of control is that it is often implemented, monitored, and enforced by an agency other than EPA or the state.

Proprietary controls are unique in that they have their basis in real property law and that they generally create legal property interests. An example of this type of control is an easement that provides access rights to a property so that an agency may inspect and monitor a cover system. A proprietary control may also be used to restrict certain activities on the property, such as excavating below a certain depth. These are powerful tools in that they can be made to "run-with-the-land" (i.e., effective if ownership changes), but they provide significant challenges because property interests are often transferred. EPA is limited by CERCLA §104(j) with regard to acquiring interests in real property. Prior to acquiring an interest in real property the state must provide an assurance that it will accept transfer of

that interest at completion of the remedial action. This requirement applies at both Fund-lead and enforcement-lead sites. Therefore, if a proprietary control involves the transfer of an interest in real property, EPA must obtain this assurance and find an appropriate entity to hold the interest following the remedial action. At Fund-lead sites this will most likely be the state. At enforcement sites, it may be the state, a PRP, or some other interested and qualified party. In addition, proprietary controls are based on state law, and EPA and many state environmental agencies have limited real estate or common law experience. This can complicate proprietary control enforcement.

Enforcement and permit tools with IC components under CERCLA Sections 104 and 106(a) include unilateral administrative orders (UAOs) and AOCs, which can be issued or negotiated to compel the land owner to limit certain site activities at both federal and private sites. In addition, CERCLA 122(d) authorizes the use of consent decrees at privately-owned sites. Enforcement devices are some of the more common ICs. The strength of these types of tools is that EPA or states can directly enforce them (rather than relying on a local agency for governmental controls or using real estate common law for proprietary controls). The major weakness is that they may be enforceable only against the signatory, recipient, or permitee (i.e., may not run with the land to bind future property owners).

> Unilateral Administrative Order (UAO) – When EPA negotiates with a Potentially Responsible Party (PRP) to do cleanup work at a Superfund site, the agreement may be documented in an administrative order on consent (AOC). If the negotiations fail, EPA has the authority to compel the PRP to do the cleanup by issuing a unilateral administrative order (UAO). Administrative orders are issued under CERCLA sections 104 and 106.

Informational devices are types of devices that only provide information or notification that residual or capped contamination may remain on-site. These types of tools are common at lead cleanups to both provide notification of residual contamination and to provide information that may modify behavior to minimize the potential for unacceptable exposure. Examples include placing a property on a state contaminated properties registry, developing deed notices, and providing periodic lead-education advisories to residents. Due to the nature of informational devices and their non-enforceability, it is important to carefully consider the objective of this category of ICs. Informational devices are most likely to be used as a secondary "layer" to help ensure the overall reliability of other ICs.

There is typically an inverse relationship between the amount of cleanup and the degree of reliance on ICs (i.e., the more cleanup, the less reliance on ICs). EPA tends to focus on a number of considerations when evaluating the long-term viability and amount of redundancy required for ICs at a particular site. EPA guidance strongly advocates the use of ICs in "layers" and/or in "series" (EPA, 2000f). Layering ICs means using multiple ICs concurrently (e.g., a consent decree, deed notice, educational/informational devices and a covenant). Using ICs in series is appropriate when IC

mechanisms are removed or changed as site circumstances change, such as reduction in restrictions during the clean-up life-cycle. As illustrated in the descriptions of the different categories of ICs, there are inherent strengths and weaknesses with each type. The goal is to obtain the best mixture of ICs to manage the risk at a site over the long-term. There are many important factors to consider when determining how many ICs are required at a site. The following is not intended to be a comprehensive list, but rather illustrative of the site-specific nature of these types of decisions. A few common considerations include: (1) the type of enforcement mechanism used (consent decree, order, permit, ordinance); (2) who will enforce the mechanism (i.e., EPA, the state, local agency, third party, etc.); (3) who the intended IC will effect and how; (4) the level of sophistication of the party implementing the cleanup and those remaining on the property; (5) the expected property use (likelihood of redevelopment and/or resale); and (6) the degree of cooperation exhibited by the parties to the cleanup. Since ICs can impact future development at sites, it is important to work cooperatively to determine the appropriate mix of ICs. The objective is not to use as many layers of ICs as possible, but rather to strike a balance that gives the regulators the certainty that the site remedy will be protective over time while maximizing the site's future beneficial use.

At many large lead sites, GIS systems are used to track the cleanup status of properties located on the site. The tracking system facilitates the monitoring of ICs and the maintenance of the remedy. GIS systems can be operated by local governments, state governments or PRPs.

6.8 CLEAN-UP DOCUMENTATION

Upon confirmation that initial yard sampling indicates a given residential yard does not exceed the lead clean-up level for the site, or upon the completion of the cleanup of a residential yard, a letter ("clean" letter) should be sent to the property owner documenting that EPA considers the lead level in the yard to be below the level of human health concern. Prior to issuing a "clean" letter, a property closeout form should be signed by the property owner, which documents the owner is satisfied with the remediation of the property. Examples of property closeout forms are proved in Appendix G. Any areas that are not cleaned up via the owner's request, such as gardens, should be noted in the "clean" letter. If contamination is not cleaned up to depth, this fact, along with protections (i.e., barriers/markers) that are put in place, should be stated in the "clean" letter. The "clean" letter provides official documentation to the property owner for use in future property sales or transactions. Sample "clean" letters are provided in Appendix H.

6.9 ENFORCEMENT

The project manager should strive to characterize all residences within the identified zone of contamination, and achieve cleanup at all residences where lead concentrations exceed the clean-up level. At all residential clean-up sites, a percentage of homeowners typically will refuse to grant access to EPA for sampling and/or for cleanup. In order to meet remedial goals of protecting a community, all residences suspected of being located within a zone of contamination should be sampled. It is important to work with the landowner and be sensitive to a landowner's concerns regarding property access. The project manager should educate the landowner of the dangers that lead contamination may pose. If a landowner still refuses to grant access, the Region should consider issuing an access order for sampling (EPA, 1990c).

An owner of residential property on a Superfund site may be potentially liable under CERCLA § 107(a)(1). However, EPA, as an exercise of enforcement discretion, generally will not take CERCLA enforcement actions against an owner of residential property unless the residential homeowner's activities lead to a release or threat of release of hazardous substances resulting in the taking of a response action at a site. (See Policy Towards Owners of Residential Property at Superfund Sites (July 3, 1991)). Additionally, under CERCLA a residential property owner may qualify for protection from CERCLA liability as a contiguous property owner, bona fide prospective purchaser, or innocent landowner. Under both the statute and EPA's policy, a residential property owner is expected to cooperate with EPA and the person taking the response action. This obligation includes providing access and information as requested, agreeing to comply with land use restrictions relied on in connection with the remedy, and not impeding the effectiveness the effectiveness or integrity of institutional controls. (See CERCLA §§ 101(40)(B)-(H), 107(q)(1)(a), 101(35)(A)-(B)). The project manager should work to inform and educate an owner of EPA's expectations for cooperation in connection with the remedy. If necessary, to meet the commitments of the remedy, EPA should consider taking appropriate steps, such as issuing a UAO, to secure the cooperation of an uncooperative landowner.

If some properties are not addressed under site response actions (e.g., current homeowners with no young children or women of child-bearing age), then consideration should be given to establishing a trust fund (under state authority or local law), to be administered by a local government, for the cleanup of the property at a future date, when the property is transferred (e.g., by sale) to a new owner (see text box). Buyers of contaminated properties could make use of the fund to have the property cleaned up at their discretion.

Example Trust Fund – At the Bunker Hill Superfund Site, a number of property owners refused to have their residential yards cleaned up. Without any obvious need to cleanup the property right away, e.g. an unpaved, contaminated driveway that threatens to recontaminate the neighborhood or a child living at the residence or next door, the PRPs for the site were willing to give the State funds to set aside in an interest bearing account to clean up the properties in the future, when the property changes hands. Property status is then monitored by the local Health District as part of the institutional controls program. The State then manages the funds to ensure maximum interest accrual in an irrevocable trust and disbursement according to the limitations set up in the trust -- for residential property cleanup. Cleanup then occurs under State oversight at the time new owners buy the property thereby ensuring families with children that move into the community are protected.

In the case of rental properties, EPA should order access for cleanup by UAO to all owners of contaminated rental property who refuse access. To ensure the protection of occupants, enforcement of the UAO may be necessary to clean up all rental properties with contamination greater than the clean-up level.

7.0 FIVE-YEAR REVIEW

Five-Year Review – Pursuant to section 121 of CERCLA and the NCP, remedial actions which result in any hazardous substances, pollutants, or contaminants remaining at the site above levels that allow for unlimited use and unrestricted exposure need to be reviewed every five years to ensure protection of human health and the environment.

CERCLA §121(c) requires an assessment of certain remedial actions every five years on sites where contamination has been left on site (EPA, 2000a). Guidance for conducting five-year reviews has been issued (EPA, 2001h). The purpose of a five-year review is to evaluate the performance of a remedy to determine if the remedy continues to be protective of human health and the environment. Typically, at large lead sites, such as mining and smelting sites, the volume and areal extent of contamination is such that total removal of all contamination above the health-based risk level is economically impractical. Contaminated wastes are generally left on site and covered with soil. The remedy for these types of sites typically includes some type of IC to address residual or encapsulated contamination. A five-year review can determine whether the remedy is stable (i.e., soil covers are undisturbed, and clean areas are not being recontaminated from sources remaining on the site). The review should also assess the ICs that were established for residual source control to determine their effectiveness in protecting human health. As described below, the five-year reviews at large lead sites may involve the collection and evaluation of substantial quantities of data and require significant up-front planning. Much of the following discussion may not apply to small sites.

At many sites, an exposure study has been performed prior to any clean-up activities to determine blood lead concentrations of children in the community. A follow-up exposure study of residents should be conducted during the five-year review to determine if the concentrations have decreased below levels of concern. If the blood lead concentrations have not decreased to acceptable levels, additional environmental studies and individualized, follow-up exposure investigations should be conducted to determine the pathways of exposure that may need to be addressed. Long-term exposure studies can be very useful in understanding exposure trends at a site. They also can be useful to ensure that no pathways of exposure have been missed and to help identify areas of the site that have been recontaminated. In this manner, the project manager can use health data as a means to "double check" the effectiveness of the remedy and to corroborate environmental data. However, blood lead data from limited sampling should not be used as the only metric for gauging the success of a remedy, even if it can be used to identify specific problems. The project manager should coordinate with ATSDR and the local health district with respect to planning and funding such a program.

The five-year review should include resampling at a percentage of each type of property that was remediated during the clean-up actions. A baseline level of resampling should be designed to achieve a

pre-specified level of statistical significance and power. This sampling should assess the potential for recontamination that may be occurring, and may help identify any pathways that may have been missed during remediation. Any sampling that indicates widespread or clusters of soil levels above clean backfill concentrations should be monitored over time to determine if an upward trend exists that may jeopardize the remedy.

Additionally, some level of house dust sampling should occur to determine if levels are rising or falling. House dust, being a primary exposure pathway, should be used as one indicator of remedy effectiveness and also used to detect the presence of recontamination. Lead concentrations in house dust levels often correlate to interior LBP, which is not usually addressed by Superfund (Appendix B). Therefore, interior paint sampling should also be conducted as a component of the risk assessment to aid in determining the source of the lead loading to dust.

At large lead sites, remedy protectiveness issues will often relate to the implementation and management of ICs and recontamination of areas previously cleaned. The five-year review should evaluate the effectiveness of the site ICs and recommend corrections to address any deficiencies that are identified. In order for a five-year review to be effective at sites where ICs are a component in ensuring the effectiveness of the remedy, there should be: (1) clear documentation of the specific type of ICs that were to be implemented, and (2) accurate and complete tracking of subsequent activities and changes in property use following completion of the Superfund remedy.

The following are possible deficiencies for several types of commonly-used ICs and other control measures taken to ensure the protectiveness of the remedy:

- HEPA vacuum loan program not being broadly used.
- Information on interior home cleaning not being widely distributed.
- Lack of access control along rights-of-way, and in unremediated areas.
- Inadequate decontamination of vehicles leaving areas of existing contamination.
- Erosion of unremediated areas onto remediated properties.
- Lack of or inadequate disposal area for snow (that contains contaminated soil).
- Lack of drainage infrastructure and maintenance by local entities.
- Uncontrolled utility excavation in areas with contamination at depth.
- Inadequate road maintenance in areas where contamination exists at depth.
- Inadequate disposal capacity to handle IC-generated wastes.
- Discontinuation of, or diminishing, health education program.
- Decrease of blood lead monitoring.
- Complicated/unfounded ICs and/or change in local government acceptance of ICs.

8.0 FEDERAL FACILITIES

The purpose of this section includes the following: (1) to provide direction to EPA federal facility project managers who oversee response actions involving lead contamination of soils from LBP in residential areas of federal facilities; (2) to build and elaborate on the joint March 1999 EPA and DOD Principles Memorandum (DOD/EPA, 1999a) and the December 1999 Lead-Based Paint Interim Field Guide (DOD/EPA, 1999b); (3) to address situations where the DOD service component will conduct the response actions and the regulatory agencies will provide oversight; and (4) to address the unique considerations that arise when the federal government transfers LBP-contaminated property that is subject to CERCLA §120(h) to non-federal parties (e.g., states, local governments, local reuse authorities [LRAs], and private entities, etc.).

While existing policy, guidance, and directives on lead contamination are applicable at federal facilities, property transfer issues present unique requirements that necessitate this section. This section applies to properties that will be transferred for residential use which are contaminated with lead due to LBP or to properties/parcels whose use would expose sensitive populations (e.g., infants, toddlers, small children, nursing mothers) to unacceptable exposure to lead after the properties are transferred to non-Federal entities.

Beginning in 1995, EPA and DOD began to address policy differences on the clean-up levels for lead in soils from LBP. In 1998, Sherri Goodman, then Deputy Under Secretary of Defense (Environmental Security) and Tim Fields, Assistant Administrator for OSWER, reached agreement on the management of LBP at residential and non-residential areas at BRAC properties. In March 1999, this agreement was formalized as the 'Principles Memorandum' (DOD/EPA, 1999a). The Principles Memorandum stated that for residential areas located on BRAC sites, Title X procedures provide an efficient, effective, and legally adequate framework for addressing LBP in residential areas, and that as a matter of policy, CERCLA/RCRA would apply in limited circumstances. EPA and DOD agreed that generally for residential areas that were being transferred, Title X regulations would apply and that CERCLA/RCRA would apply in limited circumstances. Residential real property is defined by Title X as real property on which there is situated one or more residential dwellings used or occupied, in whole or in part, as the home or residence of one or more persons. It is important to note that Title X defines residential property differently than the Handbook.

For federal property transfers subject to CERCLA where there is a concern about lead contamination to soils from LBP, EPA Regions, where they are involved, will need to make a determination whether the property meets the requirements of CERCLA §120(h)(3). This section of CERCLA outlines deed requirements for transferring property and requires covenants indicating that all

remedial actions have been taken at the site. Federal property contaminated with lead from LBP should be evaluated based on its use, or its intended reuse, before the property has been sold or transferred to another private entity. EPA's evaluation of the transfer should be based on an evaluation of lead contamination by either relying on existing and available information gathered through a combination of file searches and a review of existing data and/or a site risk assessment, which may require the collection and analysis of additional soil samples.

The soil sampling design should be specific to the site. The actual or suspected presence of lead contamination in soil does not necessarily require sampling. Factors to be considered before designing a sampling plan include, but are not limited to, the nature of the facility's operations, its operating records, the age of the buildings/structures under consideration, the maintenance schedule for the buildings/structure, visual inspection, and future use. Based on these factors, it may be reasonable to conclude that the potential risks posed by lead may be acceptable and no further evaluation is needed. It may also be important to consider the ultimate disposition of the property once it leaves federal control. For example, the structures may be scheduled to be demolished, so that the abatement of the hazard may be addressed in the demolition process and may negate the need to conduct clean-up activities.

The EPA project manager and, as appropriate, an EPA risk assessor should work with their federal, state, and local government counterparts to develop a sampling design, where required, that would be scientifically appropriate, minimize the cost of sampling, and provide the information required for risk management decisions. As appropriate, the local redevelopment or reuse authority should be consulted as well. Information from the sampling effort could result in different outcomes: a "no further action decision", a conclusion that more extensive sampling is necessary, or, in some cases, a response action. All of these potential outcomes should be discussed with the lead federal agency, and others as appropriate, prior to the initiation of sampling.

If there is insufficient knowledge to make a conclusion about the risk at the site or if the initial sample results indicate an unacceptable risk from lead, data may be collected by a focused sampling of an environmental media to develop an improved understanding of the risk that may be posed by the lead exposure. It may be appropriate to determine that after visual inspection and/or focused sampling, and after consultation with an EPA risk assessor, the lead from the area may not pose a significant risk that requires further evaluation. Risk evaluations should be based upon a number of factors including the reasonably anticipated future land use, exposure potential, ICs proposed or in place, and bioavailability. The Handbook user is encouraged to obtain detailed information on ICs for federal facilities in the document "Institutional Controls and Transfer of Real Property under CERCLA Section 120(h)3(A), (B), or (C)" (EPA, 2000g).

If the property has been used or will be reused as residential real property after transfer, the EPA project manager should verify that the lead federal agency has followed the Title X regulations and policies regarding sampling and risk assessment. As a guide to assist site managers in understanding Title X regulations and policies, EPA and DOD jointly issued a Field Guide (DOD/EPA, 1999b) that is used by EPA and DOD field personnel when assessing hazards due to LBP. The field guide contains information on performing a Title X paint inspection and risk assessment and outlines the requirements for abating soil contaminated by LBP

The Title X program, through the implementation of the new Title IV of TSCA, establishes certification programs and work practice standards to regulate LBP hazard evaluation and abatement in target housing and child-occupied facilities. There are two types of evaluations covered by Title X. The first evaluation is a paint inspection that includes a surface-by-surface inspection to determine the presence of LBP. All painted surfaces with distinct painting histories are sampled. Usually the paint inspection is done by a combination of portable XRF devices and paint chip sampling.

The second evaluation is a risk assessment to determine if LBP hazards exist. A risk assessment includes taking samples of all deteriorating paint, dust, and soil. The final report recommends methods to deal with all LBP hazards that were found, which could include interim controls or abatement. A comprehensive evaluation consists of a combination of a paint inspection and risk assessment. Paint inspections and risk assessment conducted in accordance with Title X must be performed by certified personnel. All results, whether positive or negative, must be disclosed at the time of sale or rental.

The final TSCA 403 regulation (EPA/HUD, 2001), defines a soil-lead hazard as bare soil on residential real property, or on property of a child-occupied facility, that contains concentrations of lead equal to or exceeding 400 ppm in the play area or an average of 1,200 ppm in the rest of the yard. EPA and DOD have agreed that as a matter of policy, for bare soil with lead concentration between 400 ppm and 1,200 ppm, the Service, in consultation with the EPA, has the option of abatement or interim controls. Based on the final HUD 1012/1013 regulations (24 CFR Part 35) (HUD, 2001), federal agencies can transfer the control and abatement requirements to the purchaser, but by law the federal agency is responsible for performing the LBP inspection and risk assessment and must assure that through contractual mechanisms, the purchaser has performed the abatement of the soil in accordance with Title X.

In cases where the EPA project manager makes a determination that actions taken to address LBP hazards are sufficient (following the requirements outlined in the Field Guide), EPA should agree with the federal agency on the transfer documents and the covenant that all remedial action necessary to protect human health and the environment with respect to any such substances remaining on the property has been taken before the date of such transfer . In the case of BRAC sites, the EPA project manager can agree on the Findings of Suitability to Transfer (FOST) or Findings of Suitability to Lease (FOSL) language, and/or the operating properly and successfully (OPS) determination as required by CERCLA. When an EPA project manager has unresolved questions as to whether actions at residential areas meet the requirements of CERCLA, she/he should raise these issues to the federal agency and provide an opportunity for response. In the case of BRAC sites, it is proper to highlight these concerns in EPA's comments on the FOST/FOSL. Efforts should be made to determine that the purchaser is fully aware that EPA has questions about the condition of the property.

Finding of Suitability to Transfer (FOST) – A process that has been established to identify and prepare property for transfer by deed. Such transfers are usually undertaken at a property where environmental response is not needed or has been taken. However, under certain conditions, new authority now permits earlier transfer. The FOST process also looks at the compatibility of an anticipated reuse with completed restoration activities and identifies restrictions necessary to protect human health and the environment.

Finding of Suitability to Lease (FOSL) – A process that has been established for leasing of property that cannot be transferred by deed because environmental restoration activities are still ongoing. The FOSL process also looks at the compatibility of a proposed reuse with ongoing restoration activities and identifies restrictions necessary to protect human health and the environment and prevent interference with the cleanup.

TITLE X AND EPA'S TOXIC SUBSTANCES CONTROL ACT (TSCA) TITLE IV LEAD PROGRAM

TITLE X AND EPA'S TOXIC SUBSTANCES CONTROL ACT (TSCA) TITLE IV LEAD PROGRAM

Background

The Housing and Community Development Act of 1992 (PL102-550) contained Title X the "Residential Lead-Based Paint Hazard Reduction Act of 1992" (HUD, 1992). Even though this was a U.S. Department of Housing and Urban Development (HUD) authorization bill, it established a series of requirements for EPA. Title X includes a new Title IV of the Toxics Substances Control Act (TSCA). The sections that address EPA alone have section numbers in the four hundred (400) series, such as Section 403, Health Based Standards, whereas the HUD portions have numbers in the one thousand (1000) series, such as Section 1015, Task Force. There is one section, Section 1018, that Congress required both HUD and EPA to jointly issue a rule on disclosure.

Overview

Title X addresses LBP and LBP hazards and requires EPA and HUD to issue regulations to address those items. Title X's emphasis is on actual hazards such as deteriorating paint, lead in dust, or lead in soil versus potential hazards such as intact paint. Generally, Title X does not mandate inspections, risk assessments, abatements of LBP, or LBP hazards. The exceptions are HUD program related actions (Section 1012) or when a federal agency disposes of a property that will be used for residential purposes (Section 1013). However, if you choose to do an inspection, risk assessment, or abatement, Title X establishes certification requirements and work practice standards that must be followed. Title X requires disclosure at the time of sale or rental (Section 1018) and the provision of a brochure *Protect Your Family from Lead in Your Home* (EPA, 1999a), before rehabilitation (Section 406b). EPA may authorize state programs to operate in lieu of the federal program for the 400 series regulations but not Section 1018. See Appendix A for a full discussion of Title X.

Scope of Title X

Title X contains specific classes of structures that it regulates. The first category is "target housing", which is defined as "...any housing constructed prior to 1978 except housing for the elderly or persons with disabilities (unless any child who is less than 6 years of age resides or is expected to reside in such housing for the elderly or persons with disabilities) or any 0-bedroom dwelling."

The second category is "child occupied facilities", which are defined as "... a building or a portion of a building, constructed prior to 1978, visited regularly by the same child, 6 years of age or under, on at least two different days within any week (Sunday through Saturday period), provided that each day's visit lasts at least 3 hours and the combined weekly visit lasts at least 6 hours, and the combined annual visits last at least 60 hours. Child-occupied facilities may include, but are not limited to, day-care centers, preschools and kindergarten classrooms" (EPA, 2001a).

As of December 2001 target housing and child occupied facilities are the only classes of structures for which EPA has issued final regulations.

CERCLA 121(e)(1) exempts any response action conducted entirely on-site from having to obtain a federal, state, or local permit, where the action is carried out under §121. In general, on-site actions need to comply only with the substantive aspects of ARARs and not with the corresponding administrative requirements. Therefore, the administrative requirements laid out under TSCA 402 and 403 are not considered ARARs for actions conducted entirely on-site.

More Information

Section 405 requires EPA to establish a Hot Line and Clearing House for lead. This has been done and the National Lead Information Center's toll free number is 1-(800)-424-LEAD. Additionally the EPA web site at www.epa.gov/lead has all the rules, fact sheets, and guidance documents that the EPA Office of Pollution Prevention and Toxics has developed.

Description of the Sections of Title X

Title X Final Rules in Effect for ONLY Target Housing:

Section 1012. This section establishes the requirements for those who get assistance or mortgage insurance from HUD. The requirements are HUD program specific, but only pertain to those who are involved with a particular HUD program.

Section 1013. This section establishes the requirements for federal agencies that dispose of target housing that will be used for residential purposes.

Section 1018. Section 1018 requires that sellers and landlords disclose known LBP and LBP hazards and provide available reports to buyers and renters. Sellers and landlords must also provide a copy of *Protect Your Family from Lead in Your Home* (EPA, 1999a).

This is a joint rule between EPA and HUD. Section 1018 does not include "child occupied facilities"; EPA developed the concept of "child occupied facilities" under TSCA Title IV, the term is only in effect for TSCA four hundred (400) series rules.

TSCA Final Rules in Effect for ONLY Target Housing and Child Occupied Facilities:

Section 402/404 State Certification Programs establishes a nationally consistent federal Program for the certification of individuals and firms engaged in training, paint inspections, risk assessments, and certification of abatement workers, supervisors and training providers. There are two aspects of the program. States and tribes are encouraged to establish a program that as a whole, is at least as protective as EPA's federal program. The state programs can be more protective. When a state program is approved, it becomes the federal program in that state.

If the state or tribe does not establish an acceptable certification program, EPA operates the national program in that state. Much of the work is done in the EPA Regional Office. As of December 2001, 39 states, the District of Columbia, and 2 tribes have EPA authorized programs. Two states with large populations, which do not have authorized programs, are New York and Florida.

Section 403 establishes hazard standards for lead in paint, dust, and soil. Lead-based paint is a hazard if (1) it is deteriorated; (2) it is present on a friction surface that is subject to abrasion and the dust-lead levels on the nearest horizontal surface are equal to or greater than the applicable dust hazard standard; or (3) it is present on any chewable surface on which there is evidence of teeth marks. (Lead-based paint is statutorily defined as paint containing 1.0 milligram or more lead per square centimeter or 0.5% or more lead by weight.) Dust is a hazard if it contains 40 micrograms or more lead per square foot on floors or 250 micrograms or more lead per square foot on window sills. Soil is a hazard if it contains 400 parts per million or more in play areas or 1,200 parts per million or more in the rest of the yard.

This regulation also established the following clearance levels for interior dust: 40 micrograms lead per square foot for floors, 250 micrograms lead per square foot for window sills, and 400 micrograms lead per square foot for window troughs.

EPA's Section 403 rule was intended to prioritize risks as opposed to being inclusive of situations in which risks of concern exist. Per the rule preamble, *"The hazard standard in this TSCA rule was intended as a ''worst first'' level that will aid in setting priorities to address the greatest lead risks promptly at residential and child-occupied facilities affected by lead-based paint"* (EPA, 2001a). While identification of lead hazards (as defined under TSCA) is a necessary part of the facility reuse process, a minimal approach that would insure only that the letter of the hazard standards are met may not protect against some important risks.

Section 405 establishes standards of environmental sampling laboratories. The National Lead Laboratory Accreditation Program (NLLAP) is administered by the American Industrial Hygiene Association and the American Association for Laboratory Accreditation. All laboratory samples must be analyzed by an NLLAP accredited laboratory.

Section 406b requires that the pamphlet *Protect Your Family from Lead in Your Home* (EPA, 1999a) be distributed no more than 60 days before a renovation in the home.

TSCA Rules Being Developed

Section 402. Renovation and remodeling requirements for target housing and child occupied facilities are being drafted as a proposed rule. Requirements for bridges and structures constructed prior to 1978 are being drafted for re-proposal. Both of these could include training, certification, and work practice standards.

Lead-based Paint Debris. This rule was not required by Title X, but the need was clearly there to treat portions of the debris from lead-based activities differently than the RCRA requirements. There are two categories of waste discussed. First is the paint chips and dust, sludges and filtercakes, wash water and contaminated and decontaminated protective clothing equipment that would continue to be subject to all the requirements of RCRA. Second is the "lead-based paint architectural component debris", which would be exempt from the Toxicity Characteristics rule including Toxicity Characteristic Leaching Procedure (TCLP) testing for lead only. This would allow disposal of these components at construction-demolition (CD) landfills.

Although the Pb Debris Rule is still being developed, in the interim, **EPA has issued a Memorandum that "Regulatory Status of Waste Generated by Contractors and Residents from Lead-Based Paint Activities Conducted in Households" - signed July 31, 2000.** This memo clarifies the regulatory status of waste generated as a result of LBP activities (including abatement, renovation activities, and remodeling) in homes and other residences. This memo explains why LBP generated by contractors in households is "household waste" and thus excluded from the RCRA Subtitle C hazardous waste regulations. The household exclusion applies only to waste generated by either residents or contractors conducting LBP activities in residents. As a result, LBP waste from residences can be discarded in a municipal solid waste landfill or a municipal solid waste combustor.

APPENDIX B

1998 OSWER Directive 9200.4-27P (‘Clarification’)

9200.4-27
EPA/540/F-98/030
PB98-963244

OSWER Directive # 9200.4-27P

MEMORANDUM

SUBJECT: Clarification to the 1994 Revised Interim Soil Lead Guidance for CERCLA Sites and RCRA Corrective Action Facilities

FROM: Timothy Fields, Jr.
Acting Assistant Administrator

TO: Regional Administrators I-X

PURPOSE

This directive clarifies the existing 1994 Revised Interim Soil Lead Guidance for CERCLA Sites and RCRA Corrective Action Facilities, OSWER Directive 9355.4-12. Specifically, this directive clarifies OSWER's policy on (1) using EPA's Science Advisory Board (SAB) reviewed Integrated Exposure Uptake Biokinetic Model (IEUBK) and blood lead studies, (2) determining the geographic area to use in evaluating human exposure to lead contamination ("exposure units"), (3) addressing multimedia lead contamination and (4) determining appropriate response actions at lead sites. The purpose for clarifying the existing 1994 directive is to promote national consistency in decision-making at CERCLA and RCRA lead sites across the country.

BACKGROUND

OSWER Directive 9355.4-12, issued on July 14, 1994 established OSWER's current approach to addressing lead in soil at CERCLA and RCRA sites. The existing directive established a streamlined approach for determining protective levels for lead in soil at CERCLA sites and RCRA facilities as follows:

- It recommends a 400 ppm screening level for lead in soil at residential properties;
- It describes how to develop site-specific preliminary remediation goals (PRGs) at CERCLA sites and media cleanup standards at RCRA Corrective Action facilities for residential land use; and,
- It describes a strategy for management of lead contamination at CERCLA sites and RCRA Corrective Action facilities that have multiple sources of lead.

The existing interim directive provides direction regarding risk assessment and risk management approaches for addressing soil lead contaminated sites. The OSWER directive states that, " ... implementation of this guidance is expected to provide more consistent decisions across the country ..." However, since that directive was released, OSWER determined that clarification of the guidance is needed. Key areas being clarified by issuance of this directive include: (1) using the IEUBK model and blood lead studies, (2) determining exposure units to be considered in evaluating risk and developing risk management strategies, (3) addressing multimedia lead contamination and (4) determining appropriate response actions at residential lead sites. The existing directive provides the following guidance on these areas:

1. The OSWER directive recommends using the Integrated Exposure Uptake Biokinetic (IEUBK) Model for Lead in Children (Pub. # 9285.7-15-1, PB93-963510) for setting site-specific residential preliminary risk-based remediation goals (PRGs) at CERCLA sites and media cleanup standards (MCSs) at RCRA corrective actions Facilities. The directive states that the IEUBK model is the best tool currently available for predicting the potential blood lead levels of children exposed to lead in the environment. OSWER's directive also recommends the evaluation of blood lead data, where available, and states that well-conducted blood lead studies provide useful information to site managers. The directive however recommends that "... blood lead data not be used alone to assess risk from lead exposure or to develop soil lead cleanup levels."

2. The directive describes OSWER's risk reduction goal as "...generally, OSWER will attempt to limit exposure to soil lead levels such that a typical (or hypothetical) child or group of similarly exposed children would have an estimated risk of no more than 5% of exceeding a 10 : g/dl blood lead level." The directive also states that "... EPA recommends that a soil lead concentration be determined so that a typical child or group of children exposed to lead at this level would have an estimated risk of no more than 5% of exceeding a blood lead of 10 : g/dl." OSWER generally defines an exposure unit as a geographic area where exposures occur to the receptor of concern during the time of interest and believes that for a child or group of similarly exposed children, this is typically the individual residence and other areas where routine exposures are occurring.

3. The directive recommends that risk managers assess the contribution of multiple environmental sources of lead to overall lead exposure (e.g., consideration of the importance of soil lead levels relative to lead from drinking water, paint, and household dust) which promotes development of risk reduction strategies that address all sources that contribute significantly to exposure.

4. The OSWER directive states that the IEUBK model is not the only factor to be considered in establishing lead cleanup goals. Rather, the IEUBK model is the primary risk assessment tool available for evaluating lead risk and the results of the model are used to guide selection of appropriate risk management strategies for each site.

Since the OSWER directive was issued in 1994, there has been a trend toward a more consistent approach to managing risk at residential lead sites, however, OSWER was interested in identifying areas requiring additional clarification to facilitate more effective implementation of the directive. As a first step in the process, meetings were held with various EPA Regions, States and local governments to discuss how the directive has been implemented nationally at lead sites since 1994. By participating in these meetings and by reviewing the decisions that are being made across the country, OSWER believed that clarification of certain aspects of the 1994 directive would be useful.

All of the documents and guidance referenced in this directive are available through the National Technical Information Service (NTIS) at 703-605-6000 or could be downloaded electronically from: http//epa.gov/superfund/oerr/ini_prod/lead/prods.htm.

OBJECTIVE

At lead contaminated residential sites, OSWER seeks assurance that the health of the most susceptible population (children and women of child bearing age) is protected and promotes a program that proactively assesses and addresses risk. OSWER believes that predictive tools should be used to evaluate the risk of lead exposure, and that cleanup actions should be designed to address both current and potential future risk.

While health studies, surveys, and monitoring can be valuable in identifying current exposures and promoting improved public health, they are not definitive tools in evaluating potential risk from exposure to environmental contaminants. In the case of lead exposure, blood lead monitoring programs can be of critical importance in identifying individuals experiencing potential negative health outcomes and

directing education and intervention resources to address those risks. However, CERCLA §121(b) requires EPA to select cleanup approaches that are protective of human health and the environment and that utilize permanent solutions to the maximum extent practicable. To comply with the requirements set forth in CERCLA §121(b), OSWER will generally require selection of cleanup programs that are proactive in mitigating risk and that do not simply rely on biological monitoring programs to determine if an exposure has already occurred.

To meet these objectives, OSWER will seek actions that limit exposure to soil lead levels such that a typical child or group of similarly exposed children would have an estimated risk of no more than 5% of exceeding a 10 : g/dl blood lead level. If lead is predicted to pose a risk to the susceptible population, OSWER recommends that actions be taken to significantly minimize or eliminate this exposure to lead.

The principles laid out in the **four attached fact sheets** (Appendix) support OSWER's goals by encouraging appropriate assessment and response actions at CERCLA and RCRA lead sites across the country.

This clarification directive emphasizes the following key messages regarding the four areas and encourages the users of this directive, be they EPA Regions, States, or other stakeholders, to adopt these principles in assessing and managing CERCLA and RCRA lead sites across the country. The critical elements of the attached papers are as follows:

*I. Using Blood Lead Studies and IEUBK Model at Lead Site*s:

OSWER emphasizes the use of the IEUBK Model for estimating risks for childhood lead exposure from a number of sources, such as soils, dust, air, water, and other sources to predict blood lead levels in children 6 months to 84 (7 years) months old. The 1994 directive also recommended evaluation of available blood lead data and stated that data from a well-conducted blood lead study of children could provide useful information to site managers. In summary, OSWER's clarification policy on the appropriate use of the IEUBK and blood lead studies is that:

- OSWER recommends that the IEUBK model be used as the primary tool to generate risk-based soil cleanup levels at lead sites for current or future residential land use. If Regions propose an alternative method for generating cleanup levels, they are required to submit their approach to the national Lead Sites Consultation Group (LSCG)[1] for review and comment;

- Response actions can be taken using IEUBK predictions alone; blood lead studies are not required; and

- Blood lead studies and surveys are useful tools at lead sites and can be used to identify key site-specific exposure pathways and to direct health professionals to individuals needing immediate assistance in minimizing lead exposure; however, OSWER recommends that blood lead studies not be used for establishing long-term remedial or non-time-critical removal cleanup levels at lead sites.

II. Determining Exposure and Remediation Units at Lead Sites

---

[1]The Lead Sites Consultation Group (LSCG) is comprised of senior management representatives from the Waste Management Divisions in all 10 EPA regions along with senior representatives from the Office of Emergency and Remedial Response in EPA headquarters. The LSCG is supported by EPA's Technical Review Workgroup (TRW) for lead and the national Lead Sites Workgroup (LSW). The TRW consists of key scientific experts in lead risk assessment from various EPA Regions, labs and headquarters. The LSW is comprised of senior Regional Project Managers from various Regions and key representatives from headquarters who are experienced in addressing lead threats at Superfund sites.

OSWER recommends that cleanup levels at lead sites be designed to reduce risk to a typical or individual child receiving exposures at the residence to meet Agency guidelines *(i.e*., no greaterthan a 5% chance of exceeding a 10 ：g/dl blood lead level for a full-time child resident). Therefore, it is recommended that risk assessments conducted at lead-contaminated residential sites use the individual residence as the primary exposure unit of concern. This does not mean that a risk assessment should be conducted for every yard, rather that the soil lead contamination data from yards and other residential media (for example, interior dust and drinking water) should be input into the IEUBK model to provide a preliminary remediation goal (PRG) for the residential setting. When applicable, potential exposure to accessible site-related lead sources outside the residential setting should also be evaluated to understand how these other potential exposures contribute to the overall risk to children, and to suggest appropriate cleanup measures for those areas.

III. Addressing Multimedia Contamination at Lead Sites

EPA generally has limited legal authority to use Superfund to address exposure from **interior lead-based paint**. As a policy matter, OSWER recommends that such exposures not be addressed through actual abatement activities. However, EPA Regions should promote addressing interior paint risks through actions by others (*e.g.*, potentially responsible parties (PRPs), other government programs, etc.) as a component of an overall site management strategy. Because of other competing demands on the Superfund Trust Fund, OSWER recommends that EPA Regions avoid using the Superfund Trust Fund for removing **exterior lead-based paint** and soil contaminated from lead-based paint. Superfund dollars *may* however be used in limited circumstances to remediate exterior lead-based paint in order to protect the overall site remedy (*i.e.*, to avoid re-contamination of soils that have been remediated) but generally only after determining that other funding sources are unavailable. As with interior lead-based paint abatement, EPA Regions should promote remediation of exterior lead-based paint by others, such as PRPs, local governments or individual homeowners.

IV. Determining Appropriate Response Actions at Lead Sites

In selecting site management strategies, it is OSWER's preference to seek early risk reduction with a combination of engineering controls (actions which permanently remove or treat contaminants, or create reliable barriers to mitigate the risk of exposure) and non-engineering response actions. All potential lead sources should be identified in site assessment activities. Non-engineering response actions, such as education and health intervention programs, should be considered an integral part of early risk reduction efforts because of their potential to provide immediate health benefits. In addition, engineering controls should be implemented early at sites presenting the greatest risk to children and other susceptible subpopulations.

As a given project progresses, OSWER's goal should be to reduce the reliance on education and intervention programs to mitigate risk. The goal should be cleanup strategies that move away from reliance on long-term changes in community behavior to be protective since behavioral changes may be difficult to maintain over time. The actual remedy selected at each CERCLA site must be determined by application of the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) (55 FR 8666- 8865, March 8, 1990) remedy selection criteria to site-specific circumstances. This approach also recognizes the NCP preference for permanent remedies and emphasizes selection of engineering over non-engineering remedies for long-term response actions.

This directive clarifies OSWER's policy on four key issue areas addressed in the 1994 OSWER soil lead directive in order to promote a nationally consistent decision-making process for assessing and managing risks associated with lead contaminated sites across the country. The policy presented in these specific issue areas supersedes all existing OSWER policy and directives on these subjects. No other aspects of the existing 1994 directive are affected.

IMPLEMENTATION

The principles laid out in this directive (which includes the four attached factsheets) are meant to apply to all residential lead sites currently being evaluated through the CERCLA Remedial Investigation/Feasibility Study process and all future CERCLA Sites and RCRA Corrective Action Facilities contaminated with lead. The Regions will be required to submit their rationale for deviating from the policies laid out in this directive to the Lead Sites Consultation Group. This directive does not apply to previous remedy selection decisions.

Thus it cannot impose legally-binding requirements on EPA, states, or the regulated community, and may not apply to a particular situation based upon the circumstances. EPA may change this guidance in the future, as appropriate.

Factsheet: Using the IEUBK Model and Blood Lead Studies at Residential Lead Sites

Question: What is OSWER's policy on using the IEUBK model and blood lead studies in conducting risk assessments and setting cleanup standards at residential lead contamination sites?

Answer: OSWER's policy on using the IEUBK model and blood lead studies in conducting risk assessment and setting cleanup standards is as follows:

A. Use of the IEUBK Model:

1. The IEUBK model is a good predictor of potential long-term blood lead levels for children in residential settings. OSWER recommends that the IEUBK model be used as the primary tool to generate risk-based soil cleanup levels at lead sites for current or future residential land use. If Regions propose an alternative method for generating cleanup levels, they are required to submit their approach to the National Lead Sites Consultation Group (LSCG) for review and comment.

2. Blood lead distributions predicted by the IEUBK model illustrate a plausible range of variability in children's physiology, behavior, and household conditions.

3. Response actions can be taken, and remedial goals developed, using IEUBK predictions alone.

B. Use of Blood Lead Studies/Data:

1. Blood lead studies, surveys, and monitoring are useful tools at lead sites and can be used to help identify key site-specific exposure pathways and direct health professionals to individuals needing immediate assistance in minimizing lead exposure.

2. The utility of blood lead testing results and studies depends on how representative the information is of the population being evaluated, the design of the data collection, and the quality of the laboratory analysis. To this end, OSWER recommends that EPA Regions consult with ATSDR or CDC to assess or design studies according to their intended use.

3. Many blood lead screening, monitoring, or testing programs differ from blood lead studies in that they do not attempt to identify risk factors for childhood exposure to lead sources. Although these programs may be extremely beneficial in identifying children with elevated blood lead levels and identifying candidates for referral to medical professionals for evaluation, they may not provide an accurate representation of community-wide exposure.

4. Well-designed blood lead studies may be used to identify site specific factors and pathways to be considered in applying the IEUBK model at residential lead sites. However, OSWER recommends that blood lead studies not be used to determine future long-term risk where exposure conditions are expected to change over time; rather, they should be considered a snapshot of ongoing exposure under a specific set of circumstances (including community awareness and education) at a specific time. Long-term studies may be helpful in understanding exposure trends within a community and evaluating the effectiveness of cleanup strategies over time.

C. IEUBK and Blood Lead Studies/Data:

1. Blood lead data and IEUBK model predictions are expected to show a general concordance for most sites. However, some deviations between measured and predicted levels are expected. On some occasions, declines in blood lead levels have been observed in association with lead exposure-reduction and health education. However, long-term cleanup goals should be protective

in the absence of changes in community behavior as there is little evidence of the sustained effectiveness of these education/intervention programs over long periods of time.

2. Where actual blood lead data varies significantly from IEUBK Model predictions, the model parameters should not automatically be changed. In such a case, the issue should be raised to the Lead Technical Review Workgroup (TRW) to further identify the source of those differences. Site work need not be put on hold while the issue is being reviewed by the TRW; the site manager should review other elements of the lead directive and the "Removal Actions at Lead Sites" guidance to determine appropriate interim actions to be taken at the site.

The Regions will be required to submit their rationale for deviating from the policies laid out in this factsheet to the Lead Sites Consultation Group.

Factsheet: Determining Exposure and Remediation Units at Residential Lead Sites

Question: How does OSWER define an exposure unit, and subsequently apply this definition in conducting risk assessment and risk management activities at residential lead sites?

Answer: OSWER recognizes that defining and characterizing exposure unit(s) for a site is critically important in undertaking risk assessment activities and in designing protective cleanup strategies. An **exposure unit** is defined as a geographic area where exposures occur to the receptor of concern during the time of interest and that for a child, or group of similarly exposed children, this is typically the individual residence and other areas where chronic or ongoing exposures are occurring.

Various approaches to characterizing and managing risks by exposure units have been examined by OSWER. OSWER recognizes that lead ingestion can also cause adverse health effects in adults and fetuses but believes that by adequately limiting lead exposures to young children at residential sites, these other receptors will generally be likewise protected from adverse health impacts.

EPA's goal is to protect human health and the environment under current and future exposure scenarios. At lead sites, OSWER wants to assure that children's health is protected and promotes a program that proactively assesses risks rather than relying on biological monitoring to determine if an exposure has already occurred. OSWER emphasizes actions be taken at lead sites that will minimize or eliminate exposure of children to environmental lead contamination.

To achieve the above stated goal, OSWER recommends characterizing **exposure units as exposure potential at the individual residence as the primary unit of concern for evaluating potential risk at lead contaminated residential sites**. This recognizes that there are children whose domain and activities occur principally within the confines of a particular residential property. For determining exposure potential (and ultimately developing protective cleanup levels) at the individual home, OSWER recommends the scenario to be evaluated (through use of the IEUBK Model) would be a young child in full-time residence. This approach helps achieve OSWER's recommended health protection goal that an individual child or group of similarly exposed children would have <5% chance of exceeding a blood lead concentration of 10 : g/dl. In designing community wide cleanup strategies, it is essential that non-residential areas (*e.g.*, parks, day care facilities, playgrounds, etc.), where lead exposure may occur, also be characterized with respect to their contribution to soil-lead exposure, and appropriate cleanup actions implemented.

OSWER recommends that risk management decisions for response to residential lead contamination sites focus on reducing risk at residences, but also recommends that response strategies be developed for other site locations (exposure units) where children receive exposure. Flexibility in determining appropriate response actions that provide protection at the individual residence should be considered in context of the NCP remedy selection criteria. The lead exposure issues are complex and OSWER recommends that EPA Regions try to communicate clearly the risk characterization and risk management decisions to the site residents. Affected communities must clearly understand the context of risk management decisions, how these decisions affect the health of their children, and how cleanup actions will influence the future growth and development of the community.

The Regions will be required to submit their rationale for deviating from the policies laid out in this factsheet to the Lead Sites Consultation Group.

Factsheet: Addressing Multimedia Contamination at Residential Lead Sites

Question: What is OSWER's policy on addressing multimedia contamination at residential lead sites?

Answer: OSWER recognizes that several sources of lead-contamination, including soil, ground water, airborne particulates, lead plumbing, interior dust, and interior and exterior lead-based paint may be present at Superfund sites where children are at risk or have documented lead exposure. These lead sources may contribute to elevated blood lead levels and may need to be evaluated in determining risks and cleanup actions at residential lead sites. However, there are limitations on the Agency's statutory authority under CERCLA to abate some of these sources, such as indoor lead-based paint and lead plumbing because CERCLA responses may be taken only to releases or threatened releases into the environment (CERCLA §104 (a)(3) and (4)).

When EPA's resources, or authority to respond or to expend monies under Superfund is limited, OSWER recommends that EPA Regions identify and coordinate to the greatest extent possible with other authorities and funding sources (*e.g.*, other federal agencies and state or local programs). EPA Regions should coordinate with these other authorities to design a comprehensive, cost-effective response strategy that addresses as many sources of lead as practicable. These strategies should include actions to respond to lead-based paint, interior dust, and lead plumbing, as well as ground water sources and lead-contaminated soil.

Although OSWER will encourage that EPA Regions fully cooperate in the development of a comprehensive site management strategy, OSWER realizes that complete active cleanup of these other sources may be difficult to complete due to limited funding available to other authorities. Since complete cleanups of these sources is not guaranteed, and at most sites may be unlikely, OSWER recommends that the soil cleanup levels not be compromised. In other words, the soil cleanup levels should be calculated with the IEUBK model using existing pre-response action site specific data. This is due to the fact that soil cleanup levels at residential lead sites are generally established to protect individuals, from excess exposures to soils, and house dust attributable to those soils, and are not attributable to exposure to other sources such as interior lead paint which should be managed on a residence specific basis. Remediation of non-soil lead sources to mitigate overall lead exposure at individual residences should therefore not be used to modify site-wide soil lead cleanup levels.

The recommendations provided below represent OSWER's policy on addressing lead-contaminated media and/or sources for which EPA has limited or no authority to remediate.

Interior Paint: EPA has limited legal authority to use Superfund to address exposure from interior lead-based paint. As a policy matter, OSWER recommends that such exposures not be addressed through actual abatement activities. However, EPA Regions should promote addressing interior paint risks through actions by others, such as HUD, local governments, or individual home owners as a component of an overall site management strategy. Any activities to clean up interior lead-based paint by PRPs or other parties should not result in an increase of the risk-based soil cleanup levels.

Exterior Paint: Because of other competing demands on the Superfund Trust Fund, OSWER recommends that EPA Regions avoid using the Superfund Trust Fund for removing exterior lead-based paint and soil contaminated from lead-based paint. Superfund dollars *may* be used to respond to exterior lead-based paint for protecting the overall site remedy (*i.e.*, to prevent re-contamination of soils that have been remediated) but only after determining that other funding sources are unavailable. Where other sources of funding are not available, EPA may utilize the CERCLA monies to remediate exterior lead-based paint on homes/buildings, around which soil contaminated by other sources has been cleaned up to prevent recontamination of the soil. The Superfund should not be used to remediate exterior lead-based paint where no soil cleanup has occurred. As with interior lead-based paint abatement, EPA Regions

should promote remediation of exterior lead-based paint by others, such as PRPs, local governments or individual homeowners. Cleanup activities of exterior paint conducted by PRPs or other parties should not result in an increase of the risk-based soil cleanup levels.

Interior Dust: Lead contaminated interior dust can be derived from several sources, including interior paint, home owner hobbies, exterior soil, and other exterior sources. In many cases, it may be difficult to differentiate the source(s) for the lead contamination in the dust. In general, EPA Regions should refrain from using the Superfund Trust Fund to remediate interior dust. Because of the multi-source aspects of interior dust contamination, potential for recontamination, and the need for a continuing effort to manage interior dust exposure, OSWER recommends the use of an aggressive health education program to address interior dust exposure. Such programs, administered through the local health department (or other local agency), should be implemented in conjunction with actions to control the dust source. At a minimum, the program should include blood lead monitoring, and personal hygiene and good housekeeping education for the residents. OSWER believes that EPA Regions can also support the program by providing HEPA vacuums to the health agency for use in thoroughly cleaning home interiors.

Lead Plumbing: Generally CERCLA does not provide for legal authority to respond to risks posed by lead plumbing within residential dwellings. It should be noted that the water purveyor is responsible for providing clean water to the residences. As with interior dust, OSWER recommends that EPA Regions coordinate with local agencies to establish a health education program to inform residents of the hazards associated with lead plumbing and how to protect themselves by regularly flushing, or preferably, replacing lead pipes. Soil cleanup levels should not be adjusted to account for possible remediation of lead plumbing.

Factsheet: Determining Appropriate Response Actions at Residential Lead Sites

Question: What is OSWER's position on the appropriate use of engineering and non-engineering response actions in developing risk management strategies for lead sites?

Answer: One goal emphasized in the recent third round of Superfund Reforms is for EPA to take a consistent approach in selecting and implementing both long- and short-term response actions at lead sites in all regions. One obstacle to achieving this consistency has been differing degrees of reliance on non-engineering response actions in reducing risk.

Site management strategies at lead sites typically include a range of response actions. Alternatives range from engineering controls that permanently remove or treat the contaminant source to non-engineering response actions, such as educational programs and land use restrictions. This continuum represents the range of response options available to risk managers. This position paper clarifies the relationship between engineering and non-engineering response actions in developing site management strategies.

In selecting site management strategies, OSWER's policy will be to seek early risk reduction with a combination of engineering controls (actions which permanently remove or treat contaminants, or which create reliable barriers to mitigate the risk of exposure) and non-engineering response actions. All potential lead sources should be identified in site assessment activities. Non-engineering response actions, such as education and health intervention programs, should be considered an integral part of early risk reduction efforts due to their potential to provide immediate health benefits.[2] In addition, engineering controls should be implemented early at sites presenting the greatest risk to children and other susceptible subpopulations. Community concerns should receive a high priority in site decision-making; local support is vital to the success of health intervention and education programs.

As the project progresses, OSWER's goal should be to reduce reliance on education and intervention programs to mitigate risk. The goal should be cleanup strategies that move away from reliance on long-term changes in community behavior to be protective; behavioral changes may be difficult to maintain over time. The actual remedy selected at each site must be determined by application of the NCP remedy selection criteria to site-specific circumstances. However, this approach recognizes the NCP preference for permanent remedies and emphasizes the use of engineering controls for long-term response actions. This approach also recognizes that well-designed health intervention and education programs, when combined with deed restrictions and/or other institutional controls, may be appropriate for reducing future exposure potential and may supplement engineering controls.

In instances where Regions believe that the use of engineering controls is impracticable, and education, health intervention, or institutional controls are proposed as the sole remedy, Regions will be required to consult with the LSCG.

---

[2]The actual effectiveness of health intervention and educational programs in reducing risk continues to be a subject of discussion. Anecdotal information suggests that such programs can provide short-term benefits in some populations. Rigorous statistical studies demonstrating the benefits of educational programs in preventing lead exposure are lacking. It is generally recognized that not all segments of the population will be influenced by such programs, and that long-term benefits are less certain. Local support for such programs is critical. The active (and long-term) participation of local and state public health agencies is needed in implementing institutional controls, including health intervention and education programs; without local implementation of such programs their success is uncertain. Additional research on the effectiveness of these programs is critical to consideration of their use in future cleanups.

☐ I would also like EPA to have a lead expert contact me to schedule a free inspection to identify potential lead hazards in my home and provide safety tips.

United States Environmental Protection Agency Region 6
1445 Ross Avenue, Suite 1200
Dallas, Texas 75202-2733

CONSENT FOR ENTRY AND ACCESS TO PROPERTY FOR SAMPLING

Description of property (including address) for which consent to access is granted:

> Example: XXXX Street, Texarkana, Arkansas, more particularly described as a lot measuring approximately 3,000 square feet, including a two-room wood structure of approximately 300 square feet

Name of Signatory: _____

Address: _____
_____
_____ Phone: (_____)_____

Relationship to property (e.g., owner, lessee, agent or employee of owner, etc.):

I HEREBY CONSENT to officers, employees and parties authorized by the U.S. Environmental Protection Agency (EPA), entering and having continued access to the property described above at reasonable times for the following purposes (List the activities to be undertaken on the property):
Example:

- Sample collection including: (1) the gathering of soil from the outside area of the property; (2) drawing water from the tap; and (3) vacuuming the inside area of any inhabitable structure in order to collect dust.

- Taking photographs to record the sampling process.

I realize that these actions are undertaken pursuant to EPA's response and enforcement responsibilities under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), 42 U.S.C. Sections 9601-9675. This written permission is given by me voluntarily with the knowledge of my right to refuse and without threats or promises of any kind.

This agreement expires on: _____
(Date)

I HEREBY WARRANT that I have authority to make this access agreement.

XXXX TRIBE OF OKLAHOMA

PROPERTY ACCESS CONSENT AGREEMENT
FOR SAMPLING AND TO TAKE RESPONSE ACTION

The Property which is the subject of this agreement is described as follows:

NE 1/4 SE 1/4, Section 6, Township 28 North, Range 24 East, Xxxx County, Oklahoma otherwise described as Beaver Springs Park and Tribal Office which includes the Pow Wow grounds (hereinafter the Property).

THIS ____ DAY OF _____, 1999, by authority of the Xxxx Tribal Business Committee, permission is hereby granted to officers, employees and parties authorized by the United States Environmental Protection Agency (EPA) entering and having continued access to the Property until 4:30 pm (CST) on _____, to conduct the following work (hereinafter the work):

(1) To perform necessary response actions (e.g., excavation of contaminated soil, backfilling with clean soil or gravel, and sodding or seeding) to address lead and other metals from mining waste contamination on the above-described lands in accordance with the EPA Record of Decision issued August 27, 1997;

(2) To take necessary samples of environmental media to identify lead and other metals that may be a threat to public health or welfare or the environment.

Nothing contained in this permit shall operate to delay or prevent a termination of Federal trust responsibilities with respect to the Property by the issuance of a fee patent or otherwise during the term of the work; however, such termination shall not serve to terminate the work. The Xxxx Tribal Business Committee shall notify EPA of any change in status or ownership of the Property.

The Xxxx Tribal Business Committee realizes that the work will be undertaken pursuant to EPA's Superfund authority under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), 42 U.S.C. Sections 9601-9675.

This written permission is given by the Xxxx Tribal Business Committee voluntarily with the knowledge of its right to refuse and without threats or promises of any kind.

The Xxxx Tribal Business Committee is the property owner or a responsible representative of the property owner and I, Xx Xxxx, as Chairman of that Committee, warrant that I have authority to make this access agreement.

Example of Dust Abatement Access Form

CONSENT FOR ACCESS TO PROPERTY

Name: _____ Daytime Phone Number: _____

Address(es) of Property(ies): _____

_____

I hereby consent to grant officers, employees, contractors, sub-contractors and authorized representatives of the United States Environmental Protection Agency (EPA) access to the interior of my home and/or property for the purpose of interior dust abatement. The home dust abatement program being offered at this time consists of vacuuming floors and walls with a special vacuuming system. This system is portable and compact and easy to use. A team of bonded representatives will be providing the service at no charge to the homeowner.

Videotaping of the interior of the residence will be necessary to provide backup documentation in the event of any claims. It will be necessary that someone remain at the residence for one or two days while it is being vacuumed. This lead abatement program is offered only to homeowners who have or will grant access to their property for the remediation of in their yards. These activities are necessary to interrupt the movement of lead through soil dust, house dust, and paint dust.

If you want the process completed in your home and prefer to do it yourself, please note in the appropriate space and arrangements will be made to schedule the loan of a HEPA-VAC unit to you.

This written permission is given voluntarily with the knowledge of its right to refuse and without threats or promises of any kind. I understand that , if any damage to my property results from these activities or any work conducted by the USEPA or its authorized representatives, then the USEPA or its authorized representatives shall repair or replace such damage.

_____

Date

‘ I grant access to my property for Representatives of the EPA to video and vacuum.
‘ I wish to make arrangements to vacuum myself.
‘ I do not grant access to my property.

_____

Signature

Please return as soon as possible for scheduling of work. If you should have any questions please contact [LOCAL CONTACT NAME] at [PHONE NUMBER].

City, State Zip

Dear :

The U.S. Environmental Protection Agency (EPA) has completed the cleanup of the lead contamination in your yard located at [ADDRESS, CITY, STATE], in connection with the [SITE NAME] site in [CITY, STATE] (the Site). By way of this letter, U.S. EPA is certifying that your yard has been cleaned up to less than [CLEAN-UP LEVEL] parts per million lead, the level which U.S. EPA considers protective of children's health at the Site.

Thank you for your cooperation in this clean-up effort. It has been our pleasure to work with you. If you have any questions concerning this letter or need further information, please contact me at [PROJECT MANAGER'S PHONE NUMBER].

Sincerely,

[PROJECT MANAGER NAME]
Remedial Project Manager

Dear :

The United States Environmental Protection Agency (U.S. EPA) has sampled your yard located at [ADDRESS, CITY, STATE] for lead. The results of this sampling, which are enclosed with this letter, indicate that your yard contains less than [CLEAN-UP LEVEL] per million lead, the level which U.S. EPA considers protective of children's health at the [SITE NAME, CITY, STATE]. Thus, U.S. EPA will not need to perform soil clean-up activities in your yard.

If you have any questions concerning this letter or the enclosure, please contact me at [PROJECT MANAGER'S PHONE NUMBER].

Sincerely,

Analytical results for [ADDRESS]
in parts per million (ppm) of lead:

Depth Zone (inches)	Yards		OR Quadrant			
	Front	Back	1	2	3	4
0 to 1	ppm	ppm	ppm	ppm	ppm	ppm
1 to 6	ppm	ppm	ppm	ppm	ppm	ppm
6 to 12	ppm	ppm	ppm	ppm	ppm	ppm
18 to 24	ppm	ppm	ppm	ppm	ppm	ppm
Deeper Zones (if applicable)	ppm	ppm	ppm	ppm	ppm	ppm
Drip Zone Composite	ppm	ppm	ppm	ppm	ppm	ppm

Mr. John Smith
123 N. Main
Joplin, Missouri 64108

Dear Mr. Smith,

This letter serves as written notification that a lead-contaminated soil clean-up action was performed under authority of the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 as amended by the Superfund Amendments and reauthorization Act of 1986 on property you have an interest in at the Jasper County, National Priorities Listed Superfund site. Our records show that your property located at **123 N. Main** was included in this action. The clean-up action conducted by the U.S. Environmental Protection Agency (EPA) and the U.S. Army Corps of Engineers (COE) addressed residences with soil lead levels over 800 ppm, day care facilities, and residences with children under six years of age with blood lead levels over 15 g/dL.

Briefly, the primary objective of the clean-up action on your property was to remove highly lead-contaminated near-surface yard soils that were located at your residence. In some cases trees, shrubs, flowers, and other vegetation were left in place. As a result a small amount of lead-contaminated soils may be left near the surface on your property. This small amount of contamination should not cause a health threat under normal circumstances. In the future if additional landscaping, or planting requiring excavation below six inches are done, care should be exercised to minimize recontamination.

The excavation criteria for the project was as follows:

A) From the surface to 12 inches, excavation continued until 500 ppm or less lead levels concentrations were achieved;

B) If the residual lead concentrations at a depth of one foot exceeded 1,500 ppm a "marker barrier" was placed at that depth. The marker barrier used was the temporary orange plastic construction-type fence. This material is permeable, and will allow water and plant roots to pass through it. Only a small number of properties required the installation of the barrier. The primary purpose of this marker barrier is to inhibit and alert individuals excavating in these areas in future years.

In general, all areas of the yard that exceeded 500 mg/kg lead at the surface were removed. Soil brought in to backfill the excavation contained less than 240 mg/kg lead.

IF YOU HAVE PLANS TO DO ANY EXCAVATION WORK AT YOUR PROPERTY AND YOU ENCOUNTER THE ORANGE BARRIER PLEASE CONTACT YOUR LOCAL HEALTH DEPARTMENT, THE MISSOURI DEPARTMENT OF NATURAL RESOURCES, OR THE EPA FOR GUIDANCE.

Please save this document for your permanent records. In the event you sell or transfer the property to someone you can show the next owner that a lead cleanup was performed. If you require more specific information concerning the excavation on your property, please feel free to contact me at (xxx) xxx-xxxx.

Sincerely,

(Project Manager)
