More recovery has occurred near the center of the cone, with lesser recovery near the margins, but the full magnitude of recovery is difficult to determine because wells closer to the center of the cone (De Pere and Allouez) are no longer capable of yielding water level measurements. However, observation well BN-0435 (Figure 7), situated near the center of the northern cone, has shown 35 m of recovery since installation in mid-2010, presumably after most of the potentiometric surface recovery had already occurred between 2006 to early 2010. Based on data from nearby wells in 2004–2005, as much as 67 to 88 m of recovery might have taken place at this location near the center of the northern cone between 2005 and 2016.

The southern cone shows a steady downward trend in water levels (Figure 13b) in the absence of significant changes in pumping rates (Figure 11). Reduction of pumping near the northern cone has apparently not significantly affected the southern cone. This may be due to several factors. First, the two cones are about 34 km apart. In addition, a major east–west fault is known to compartmentalize the aquifer and may act as a barrier to regional groundwater flow. Evidence for this includes changes in major ion composition and stable isotopic composition of hydrogen and oxygen on either side of the fault zone [28,29]. Additionally, pumping changes resulting from the 2016 switch to surface water by the village of Wrightstown, located between the two cones, are not captured by water level data available during this study.

Several contour maps of the potentiometric surface in the Cambrian-Ordovician confined sandstone aquifer illustrate the changes during the second transition period between 2005 and the present. Figure 9 shows a deep cone of depression centered near central Brown County that shallows between 2005 and 2015. By 2016, water levels in many central Brown County wells appear to have stabilized, but some areas continue to show increasing water levels (e.g., Figures 7 and 13a), albeit with a seasonal component due to differences in seasonal pumping rates.

While total drawdown from predevelopment conditions is more difficult to estimate for the southern cone, drawdown of at least 56.4 m has occurred in Kaukauna and Little Chute, and perhaps as much as 64 m in Kimberly. During mid-2016, SWLs in Little Chute well #3 indicated cumulative drawdown of about 78 m, although this might be temporary due to well maintenance scheduling.

6. Discussion and Implications

Globally, many areas suffer from declining groundwater levels and accelerating rates of depletion [1,54], and few aquifers have shown large-scale water level recovery due to improved management changes or alternative water supplies (e.g, [3,4,54] this study). In many cases, groundwater quality and quantity degradation occur due to increasing salinity, ground subsidence, and reduction in surface streamflow (e.g., [54]). However, the study area in northeastern Wisconsin does not suffer from these common effects because the principal aquifer is hosted by Paleozoic sandstone under confined conditions. In contrast, flowing artesian wells, flooding of quarries, and water quality changes relating to oxidation of sulfides appear to be of most concern.

6.1. Unintended Consequences

The recent transition from groundwater to surface water by 10 communities in Brown County might lead to specific unintended consequences including flowing wells, flooding of quarries, and possible spring activity. Many wells that are open to the confined sandstone aquifer have begun to flow since the transition to surface water in 2006 to 2007. These are most common to the northwest of Green Bay in the villages of Howard and Suamico. Well #3 in the village of Howard (Figure 2) began flowing in 2009 [26], and many residential and commercial wells open to the sandstone aquifer also flow seasonally or continuously in this area. This has led to concern that inactive, improperly abandoned wells might begin to exhibit flowing artesian conditions. Some of these wells may still exist and are typically located in the basements of buildings in the urban areas of Green Bay, or near former railroad fill stations, despite the long established requirement by WDNR to permanently abandon (fill and seal) these wells.

Another unintended consequence was accelerated flooding of a deep quarry resulting in flowing conditions. Also in the village of Howard, the Duck Creek Quarry penetrates the entire thickness of the Sinnipee Confining layer down to the top of the Ancell Group/St. Peter Sandstone. The quarry began filling in 2001 after the quarry ceased operation and dewatering pumps were turned off. At this time, the potentiometric surface was at or below the base of the quarry, and the flow of water was likely downward, recharging the sandstone aquifer below. Through compilation of historical photographs and direct measurements, Luczaj [55] demonstrated a change in the filling rate of the quarry that corresponded to pumping changes in the confined sandstone aquifer. Before the villages of Ashwaubenon and Howard ceased pumping groundwater in 2006 and 2007, respectively, the rate of water level rise was approximately 6.2 cm/week between 2002 and 2006. After the transition, the rate of rise of water levels in the quarry increased by 68% to 10.4 cm/week between 2007 and 2011. The quarry is only about 2.1 km south of the flowing municipal well in the village of Howard. By mid-2011, water levels reached the top of the bedrock, leading to lateral flow in unconsolidated Pleistocene sediments. This led the village of Howard to install an outfall to a nearby creek to avoid future problems. During May 2013, the quarry outfall had steady flow at approximately 530 kL/day.

Additional concerns of quarry flooding and even quarry floor buckling have been expressed by engineers regarding operating deep dolostone quarries near De Pere that approach the top of the Ancell Group [56].

Other possibilities include renewed flowing of springs and seeps in areas where fractures and other conduits allow for preferential vertical flow across the Sinnipee Group confining layer. The potential importance of such springs is now well known, but several clues suggest that preferential flow paths across the confining layer might exist. For example, recent engineering work in Green Bay has documented vertical fissures at least several meters long that cut through the Sinnipee Group dolostone [57]. While the Sinnipee Group does not have documented karst solution cavities within Brown County, other solution cavities in the same unit have been interpreted as hydrothermal solution cavities along northwest-trending structures near Chicago, Illinois [58].

Perhaps related, an enigmatic sinkhole in the Pleistocene glacial sediments occurs above one of the mapped northwest-trending faults along the East River in Allouez [22,59,60]. The origin of this sinkhole is not understood, but a connection with the confined sandstone aquifer is possible. At least one map from the late 1800s [61], when flowing artesian conditions would have been present, shows the feature to be a spring.

6.2. Current State of the Aquifer and Apparent Trends

As of 2016, water levels in the northern cone in central Brown County appear to have stabilized in many wells in the Green Bay region (Figures 9 and 13a), but some show slow, continued water level recovery (Figure 7). As described earlier, limited data are available near the center of the cone, but observation wells in Green Bay and Ashwaubenon show steady or slightly increasing water levels over time. Water levels in well BN-0435 have risen at a rate of about 6 m/year since installation in late 2010. Static water levels in Green Bay remain between about 16–27 m below ground level. Along the north side of Green Bay and north into Howard and Suamico, water levels continue to rise and are generally 3–5.5 m below ground level, and one of the wells in Howard has flowed since 2009. Water levels in BN-076 along the northern margin of the cone have risen steadily by about 1.5 m/year since 2010. In Wrightstown, located to the south between the two major cones of depression, water levels are rising at about 0.7 m/year during the past several years. Unfortunately, fewer data are available to monitor the water levels in the confined aquifer in recent years because of malfunctioning air lines, inaccessible well design, or well abandonment.

In the southern cone near the Fox Cities, water levels in most wells are steady, especially in Kaukauna, Darboy, Holland, and Forest Junction (File S2), with those wells showing the same water levels as those observed before the CBCWA transition in 2006 to 2007. However, two municipalities in the southern cone did show decreasing water level elevations. Wells in Kimberly showed overall

falling water levels, with some complex patterns due to well pumping variations, but with water levels certainly below those observed in 2005 (Figure 13b). This pattern continues a long downward trend that began during the late 1980s, with a long-term decrease in water levels of approximately 26 to 24 m over the past 30 years. Wells in Little Chute were fairly steady until a few years ago when pumping schedules for the wells were changed due to maintenance activities [62], forcing well #3 to be more heavily pumped. As a result, a rapid decline in the water level elevation has occurred, resulting in an additional 30 m of drawdown over the past 2.5 years (See File S2).

While flowing artesian wells open to the confined sandstone aquifer appear limited to the northwest of Green Bay in the villages of Howard and Suamico, it is possible that with further recovery, additional wells may begin flowing, even without further reductions in municipal or industrial well pumping rates.

6.3. Effects of Future Pumping Changes

Present groundwater abstraction from the confined sandstone aquifer in central Brown County is approximately 15.9 ML/day and is mainly comprised of industrial, and seasonal water uses. While golf course irrigation and other wells are unlikely to change significantly, potential ramifications of water use reductions by one or more major industries should be considered in future modeling efforts in the Northeast GMA. Significant reductions could lead to continued water level recovery in the aquifer approaching the predevelopment heads of around 29 m above land surface, resulting in flowing artesian well conditions similar to those seen in the early 1900s.

The recent switch by the village of Wrightstown to the Green Bay Water Utility (GBWU) surface water pipeline is unlikely to contribute much to the water level recovery in the region because of its small population (<3000 people).

6.4. Concerns over Arsenic and Sulfide Mineralization

In some regions of the world, groundwater fluctuations and water level rebound can result in major water quality changes, such as acidification and release of heavy metals. In parts of England, rising water levels threaten underground railway systems and the stability of building foundations. This is exacerbated by concerns of pH-reduced water relating to oxidation of sulfide mineralization in parts of the aquifer [54].

In Wisconsin, a significant concern regarding water quality in wells open to the confined sandstone aquifer stems from the fact that dewatering of the sandstone can occur in areas with greatest drawdown. Several wells in the central Brown County portion of the Northeast GMA reported static water level elevations below the top of the confined aquifer (File S3). While some wells are cased across the Ancell Group (Table 1), liberation of arsenic, nickel, cobalt, and other metals has been shown to be a problem in the aquifer when oxidative conditions prevail [50,51,63,64]. In the northern cone, at least five municipal or observation wells reported water levels that were below the top of the aquifer. One of these wells near the center of the cone (BN-0435) had a water level that did not reach the top of the aquifer until 2011, about four to five years after transition #2 began in central Brown County. While initial analysis of emergency backup wells does not indicate significant water quality problems [65], water quality data are limited mainly to wells that are only open to the Cambrian portion of the aquifer, potentially limiting or delaying any response in water quality resulting from oxidation of the Ancell Group.

In the southern cone, at least four wells have or once had water levels below the top of the confined sandstone aquifer in the villages of Little Chute and Kimberly. A water quality analysis for this portion of the aquifer is planned for the future, but there has been concern voiced over the potential for increased arsenic and radium concentrations as water levels decline.

6.5. Aquifer Sustainability

The sustainability of groundwater quantity in the Northeast GMA varies somewhat between the two cones of depression. After transition #2 in 2006 to 2007, the northern cone changed suddenly from

conditions of rapidly declining water levels in 2005 to a sustainable condition as of 2016. While it is possible that future suburban growth outside the regions supplied by municipal water might once again increase demand as it did between 1957 and 2007, there is significant additional groundwater capacity available in central Brown County at the present time for population growth or industrial use.

The assessment of groundwater quantity is less clear in the southern cone, and so water levels must be monitored. While many wells exhibit stable water level elevations, some wells have declining water levels. With population growth expected for northeastern Wisconsin, additional groundwater abstraction from the confined sandstone aquifer near the southern cone would put greater strain on a system where some but not all wells are showing declines in water levels.

7. Conclusions

This article reviews the history of groundwater use in a confined sandstone aquifer in northeastern Wisconsin, USA over more than a century. In the recently established Northeast GMA, two well-developed cones of depression result from pumping localized in two urban areas. Water levels in the southern "Fox Cities" cone of depression have decreased steadily for decades. In contrast, water levels in the northern "central Brown County" cone of depression have varied significantly in response to two cycles of population growth, followed by transitions from groundwater to surface water supply sources.

As of 2016, the northern portion of the Northeast GMA is considered to be in a sustainable condition, with steady or rising water levels that have recovered as much as 70 m in the past decade. In contrast, the southern region of the Northeast GMA exhibits a somewhat different set of conditions. While water levels in some wells are steady, others show slow declines, which will likely be exacerbated by continued population growth.

Supplementary Materials: The following are available online at www.mdpi.com/2076-3263/7/1/11/s1, File S1: Complete set of historical contour maps for the Northeast GMA. File S2: Selected hydrographs for municipal and observation wells in the Northeast GMA. File S3: Stratigraphic column and table showing wells in central Brown County with dewatered conditions since 2005. File S4: Water Level Data for selected municipal wells in the Northeast GMA. File S5: Water Level Data used to construct contour maps for 1990 to 2015.

Acknowledgments: We would like to thank the Wisconsin Department of Natural Resources for funding a portion of this project through the University of Wisconsin Water Resources Institute (Project numbers PRJ16FE and PRJ16BW). Additional support of this project (exploration wells) came from the United States Geologic Survey STATEMAP Program (grant number 10HQPA0003) and the Wisconsin Geologic and Natural History Survey. We also thank the numerous municipal and private high capacity well owners/operators who supplied pumping data and water level data for the early portion of this project. Nancy Quirk and Tom Landwehr (Green Bay Water Utility) allowed extensive access to historical paper records for the city's wells. Dave Vaclavik offered valuable insight into the CBCWA. We also thank Wisconsin DNR personnel Robert Smail, Wendy Anderson, and Dave Johnson for assistance with gathering additional water level and pumping data. Benjamin Cruz-Uribe provided important historical insight into the politics of the Northeast GMA and provided useful comments. Kevin Fermanich and Chris Houghton aided with GIS questions. Funding was not obtained to cover costs to publish in open access. We also thank the two anonymous reviewers for their comments on improving the manuscript.

Author Contributions: David Hart and John Luczaj developed the study design, obtained funding, and participated in fieldwork. Julie Maas collected water level and pumping data for 2004 through early 2009, and contributed to fieldwork while completing a Master's thesis. Jonathan Odekirk compiled water level and pumping data for 2009 through 2015 and participated in GIS mapping of the potentiometric surface as part of an unpublished undergraduate senior thesis. John Luczaj collected additional data on water levels and pumping and wrote the majority of the final manuscript. All authors contributed to data interpretation and final editing.

Conflicts of Interest: The authors declare no conflict of interest. The founding sponsors had no role in the design of the study; in the collection, analyses, or interpretation of data; in the writing of the manuscript, or in the decision to publish the results.

Abbreviations

The following abbreviations are used in this manuscript:

CBCWA	Central Brown County Water Authority
GBWU	Green Bay Water Utility
GMA	Groundwater Management Area
ML	Megaliters (millions of liters)
USEPA	United States Environmental Protection Agency
USGS	United States Geological Survey
SWL	Static Water Levels
WDNR	Wisconsin Department of Natural Resources
WGNHS	Wisconsin Geological & Natural History Survey
WUWN	Wisconsin Unique Well Number

The National Academies of
SCIENCES • ENGINEERING • MEDICINE

The **National Academy of Sciences** was established in 1863 by an Act of Congress, signed by President Lincoln, as a private, nongovernmental institution to advise the nation on issues related to science and technology. Members are elected by their peers for outstanding contributions to research. Dr. Marcia McNutt is president.

The **National Academy of Engineering** was established in 1964 under the charter of the National Academy of Sciences to bring the practices of engineering to advising the nation. Members are elected by their peers for extraordinary contributions to engineering. Dr. C. D. Mote, Jr., is president.

The **National Academy of Medicine** (formerly the Institute of Medicine) was established in 1970 under the charter of the National Academy of Sciences to advise the nation on medical and health issues. Members are elected by their peers for distinguished contributions to medicine and health. Dr. Victor J. Dzau is president.

The three Academies work together as the **National Academies of Sciences, Engineering, and Medicine** to provide independent, objective analysis and advice to the nation and conduct other activities to solve complex problems and inform public policy decisions. The National Academies also encourage education and research, recognize outstanding contributions to knowledge, and increase public understanding in matters of science, engineering, and medicine.

Consensus Study Reports published by the National Academies of Sciences, Engineering, and Medicine document the evidence-based consensus on the study's statement of task by an authoring committee of experts. Reports typically include findings, conclusions, and recommendations based on information gathered by the committee and the committee's deliberations. Each report has been subjected to a rigorous and independent peer-review process and it represents the position of the National Academies on the statement of task.

Proceedings published by the National Academies of Sciences, Engineering, and Medicine chronicle the presentations and discussions at a workshop, symposium, or other event convened by the National Academies. The statements and opinions contained in proceedings are those of the participants and are not endorsed by other participants, the planning committee, or the National Academies.

Acknowledgments

This Consensus Study Report was reviewed in draft form by individuals chosen for their diverse perspectives and technical expertise. The purpose of this independent review is to provide candid and critical comments that will assist the National Academies of Sciences, Engineering, and Medicine in making each published report as sound as possible and to ensure that it meets the institutional standards for quality, objectivity, evidence, and responsiveness to the study charge. The review comments and draft manuscript remain confidential to protect the integrity of the deliberative process.

We thank the following individuals for their review of this report:

Teresa Bowers, Gradient
Edward Boyle, Massachusetts Institute of Technology
Gordon Brown, Stanford University
John Dilles, Oregon State University
Joseph Graney, Binghamton University, The State University of New York
Thomas Johnson, University of Illinois at Urbana-Champaign
Lin Ma, University of Texas at El Paso
Peter Nico, Lawrence Berkeley National Laboratory
Robert Seal, US Geological Survey
Aaron Thompson, University of Georgia

Although the reviewers listed above provided many constructive comments and suggestions, they were not asked to endorse the conclusions or recommendations of this report nor did they see the final draft before its release. The review of this report was overseen by David Dzombak, Carnegie Mellon University, and Michael Kavanaugh, Geosyntec Consultants. They were responsible for making certain that an independent examination of this report was carried out in accordance with the standards of the National Academies and that all review comments were carefully considered. Responsibility for the final content rests entirely with the authoring committee and the National Academies.

The committee gratefully acknowledges the following for their presentations to the committee during open sessions: Teresa Bowers, Gradient; Michele Burgess, US Environmental Protection Agency; Jonathan Garoutte, Missouri Department of Health and Senior Services; Art Hebrank, Missouri Mines State Historic Site; Cheryl Seeger, Missouri Geological Survey; Valerie Wilder, Missouri Department of Natural Resources; Emitt Witt, US Geological Survey; and Mark Yingling, The Doe Run Resources Corporation. The committee thanks Michele Burgess and Marc Stifelman, US Environmental Protection Agency, for providing background materials to the committee during the study process and especially Greg Bach, US Environmental Protection Agency, for organizing the committee's tour of the Southeast Missouri Lead Mining District. The committee is also grateful for the assistance of Norman Grossblatt who served as the report editor.

Summary

The Superfund program of the US Environmental Protection Agency (EPA) was created in the 1980s to address human-health and environmental risks posed by abandoned or uncontrolled hazardous-waste sites. Identification of Superfund sites and their remediation can be an expensive multistep process. As part of this process, EPA attempts to identify parties that are responsible for the contamination and thus financially responsible for remediation. Identification of potentially responsible parties is complicated because Superfund sites can have a long history of use and involve contaminants that can have many sources. Such is often the case for mining sites that involve metal contamination; metals occur naturally in the environment, they can be contaminants in the wastes generated at or released from the sites, and they can be used in consumer products, which can degrade and release the metals back to the environment. Lead as an environmental contaminant associated with mining sites provides a prime example of the complexities that are involved in identifying potential sources in that it meets all the criteria noted. Given the complexities surrounding lead contamination, Congress asked EPA to commission a study by the National Academies of Science, Engineering, and Medicine to determine whether there are techniques or methods that can help to distinguish sources of lead at Superfund sites associated with mining activities. Accordingly, the National Academies convened the Committee on Sources of Lead Contamination at or near Superfund Sites, which prepared this report.

THE COMMITTEE'S TASK AND THE SOUTHEAST MISSOURI LEAD MINING DISTRICT

In brief, the committee was asked to examine the extent to which various sources contribute to environmental lead contamination at Superfund sites that are near lead-mining areas and to focus on sources that contribute to lead contamination at sites near the Southeast Missouri Lead Mining District.[1] The committee interpreted its task as a request for investigative strategies that could provide the evidence needed to identify lead sources in various environmental media. It did not consider its task to be determining lead sources; such an activity would require extensive sampling, analysis, and interpretation that the committee was not equipped to perform. As directed, the committee focused its efforts on whether sources of lead in the Southeast Missouri Lead Mining District could be distinguished by using various investigative strategies. The committee emphasizes that it did not consider exposure pathways, which would need to be considered for identifying which lead sources are contributing to human exposure.

The Southeast Missouri Lead Mining District provides a prime example of the complexities that a site might pose. It is composed primarily of three large subdistricts—the Old Lead Belt, Mine La Motte-Fredericktown, and the Viburnum Trend—and has a long history of lead mining: it began in the early 1700s and continues to this day. Some areas in Southeast Missouri are contaminated with lead, and several have been designated as Superfund sites. Determining the sources of lead at the sites, however, is complicated. First, the area is rich in naturally occurring lead-ore deposits that are at or near the surface. Second, as noted, the area has a long history of mining activities. Third, an enormous amount of wastes known as chat or tailings has been produced as a result of the mining activities; some of the waste materials have been dispersed from their original disposal sites by natural forces, such as wind and rain, and some have been intentionally transported off site. Fourth, lead has been used extensively over centuries in various products. Thus, lead at a site could result from naturally occurring deposits, from historical mining activities, from current mining activities, from consumer products, or from some combination. The following sections describe potential sources and environmental dispersal mechanisms, highlight the commit-

[1]The full statement of task is in Chapter 1 of this report.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

tee's investigative strategies and the implications for the Southeast Missouri Lead Mining District, and provide the committee's research recommendations.

SOURCES OF LEAD AND ENVIRONMENTAL DISPERSAL

Lead is a widespread, naturally occurring element that is found throughout the Earth's crust and occurs in virtually all rocks, soils, sediments, and waters at low concentrations. A variety of geologic processes can cause natural lead enrichment, and, in some cases, ore deposits are formed. Whether an ore deposit is mined depends on time, economics, technology, and natural processes. If various conditions are favorable, it might be decided to mine an ore deposit. Mining begins by physically extracting the ore; the ore is then processed to obtain a concentrate of lead minerals and smelted to obtain metallic lead, which is shipped to market for use in various consumer products (see Figure S-1). At each stage, materials are discarded, and this creates an opportunity for lead to be dispersed further in the environment. Historically, waste disposal was driven by what was easiest; thus, waste was generally discarded in the most efficient manner relative to the time and place. However, by the latter part of the 20th century, waste disposal was subject to regulatory controls and handled systematically in a mine's operating plan.

Sources of lead other than natural ones or those associated with mining can also cause environmental contamination. In the 20th century in the United States, lead was added to gasoline and paint; although those uses have been virtually eliminated, the legacy lead from them remains in soils and sediment and could be an important source of environmental contamination. Other uses of lead include plumbing materials, batteries, pesticides, agricultural amendments, ammunition, and other consumer products, such as jewelry, pottery, and glass.

Lead can be dispersed in the environment by natural processes and through intentional transport. A primary natural transport mechanism is via water. Although lead concentrations in water are generally lower than those of other dissolved species, lead can be transported in natural waters attached to colloidal or suspended particles. Depending on environmental conditions, sediment-associated lead in the river bank can be reintroduced into the river over both short and long periods. Depending on the prevailing weather, airborne transport has the greatest potential to disperse pollutants on regional and global scales because air is not confined by geographic barriers. Furthermore, transport rates of contaminants are often higher by air than by groundwater and surface waters. Intentional transport of mining materials and wastes has been an important mechanism for dispersal of lead in the environment. In the Southeast Missouri Lead Mining District, mine wastes (waste rock, tailings, and slags) were

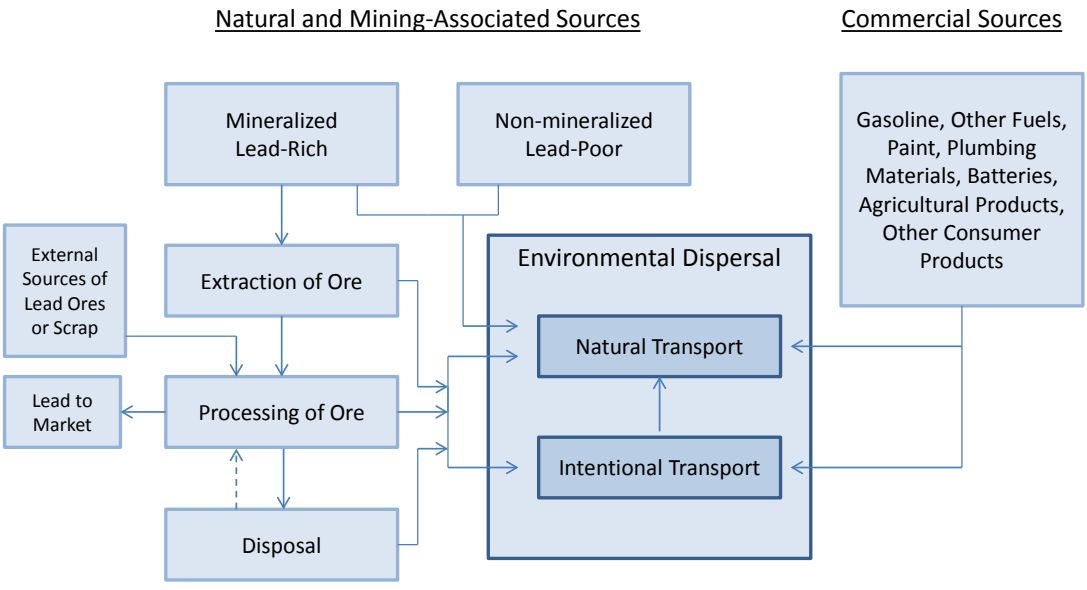

FIGURE S-1 Natural, mining-associated, and commercial sources can cause lead contamination in the environment through natural or intentional transport. *Natural transport* refers to environmental processes—such as wind, water flow, and soil erosion—that disperse materials; *intentional transport* refers to all human activities that move materials and have the potential for dispersal in the environment.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

transported for use as construction fill, roadbed materials, agricultural amendments, and building materials.

INVESTIGATIVE STRATEGIES FOR LEAD-SOURCE ATTRIBUTION

Over the years, a wide array of analytic techniques have been used to determine the relative contribution of lead from natural and anthropogenic sources to soil, sediment, water, and air with varied success. Most techniques rely on a fingerprinting approach in which unique physical or chemical properties of the lead or lead-associated materials are used to distinguish sources from one another. The committee reviewed the techniques and provides investigative strategies for determining lead sources in soil, sediment, water, and air in Chapter 4 of this report. The approaches rely on systematic collection, analysis, and interpretation of multiple lines of evidence; an investigation continues until there is sufficient confidence that an accurate lead-source attribution has been reached. The committee emphasizes that its strategies are illustrative and that the sequence of steps will depend on site-specific conditions, availability of analytic techniques, and cost and time considerations.

The investigative strategies for soil, sediment, and water begin with a site characterization.[2] The goal here is to develop a site conceptual model that can guide investigations toward likely lead sources. Ideally, site characterization should document the source locations, the form of lead and other materials associated with sources, pathways and processes by which lead could be transported from a source, and, for anthropogenic sources, the history of lead use or processing. Once basic questions have been answered, a detailed sampling protocol can be developed for the specific site, and decisions can be made as to the best analytic approaches to pursue.

For the strategies noted, the committee concluded that lead isotopic analysis should be considered first for laboratory analysis of samples. Lead-isotope ratios in geologic materials vary owing to the production of lead isotopes from the radioactive decay of uranium (U) and thorium (Th). On geologic timescales, ^{235}U decays to ^{207}Pb, ^{238}U decays to ^{206}Pb, and ^{232}Th decays to ^{208}Pb; ^{204}Pb is primordial and has no radioactive parent. Various factors, such as geologic conditions and ages, result in a wide array of lead-isotope ratios among lead-bearing ore deposits and other geologic materials. Consequently, ore deposits can have unique lead-isotope ratios (signatures) that distinguish them from each other. When lead is purified from the ores and used in industry, the lead-containing commercial products retain the lead-isotope ratios of the ore deposits used to make the products. Thus, the technique works well if there is an isotopic contrast between the sources that one wishes to distinguish, but it can be equivocal if there are overlapping isotopic ratios in the various potential sources. In most cases, some potential sources can be eliminated and thus focus the investigation on fewer possible sources.

If the isotopic analysis does not yield unique signatures or if additional confidence is needed to reach conclusions, the committee suggests other analytic techniques and methods, such as ones that rely on analysis of mineralogy, particle size, chemical speciation, or other source-associated elemental ratios or isotopes. Each method has the potential to provide additional evidence to identify lead sources. However, the committee emphasizes that even after extensive sampling and analysis it still might not be possible to attribute lead to particular sources with confidence.

IMPLICATIONS FOR THE SOUTHEAST MISSOURI LEAD MINING DISTRICT

Isotopic analytic techniques might be especially promising for distinguishing non-native ores (or products made from non-native ores) from the natural or locally mined materials in Southeast Missouri. The committee tested the possibility by compiling and comparing ^{206}Pb/^{207}Pb ratios of North American lead ores, gasoline, and paints from around the world. As noted, various ore deposits can have different lead-isotope ratios, and gasoline producers and paint manufacturers used lead mined from different ore bodies. Therefore, it is expected that in some specific cases the lead isotopic composition of gasoline and paint might differ from that of local ore bodies; in other cases, they might be the same and therefore not useful for source attribution. The lead ores from Southeast Missouri have an extremely unusual lead isotopic composition, and the isotopic composition of lead mined from Southeast Missouri (and adjacent areas in the tristate region) appears to be distinct from that of nearly all other major lead mines (and products made with lead from them) in North America.

Figure S-2 clearly shows that Southeast Missouri ores, especially those from the Old Lead Belt, have higher ^{206}Pb/^{207}Pb ratios than other ore deposits, gasoline, and paints used in the United States. The only exceptions are the lead ores from the Upper Mississippi Valley District, which were probably not produced in substantial quantities in the 20th century compared with those from Southeast Missouri, and a single sample from a house within 0.5 miles of the Herculaneum lead smelter that could be the result of lead contamination from the smelter. Thus, the committee concludes that in the case of the Southeast Missouri Lead Mining District, it is likely that lead-isotope ratios can be used to attribute the sources of lead in

[2]The investigative approach for air is different from that for the other environmental media in that it uses a tiered approach that focuses primarily on modeling for source attribution, although similar techniques to analyze airborne lead particles are noted.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

environmental media between mining materials and gasoline and paint in most cases. If there are non-native ores or other lead-containing consumer products at the site—such as plumbing materials, batteries, or pesticides—lead-isotope studies of those materials might establish their potential role as a source of lead contamination at a site.

Distinguishing lead from natural (background) sources and lead from local mining materials or waste is much more challenging in contaminated soil. Natural and mined materials from the same region will typically contain lead that exhibits similar lead isotopic composition, and this would hinder the use of lead isotopic analysis to determine source. However, one might be able to use other methods alone or in combination—such as analysis of grain size, structure, and composition of soil particles, and depth distributions of metals in soils—to attribute potential sources. For example, smelter-derived particles in soils often contain spherical grains that are composed of sulfides, oxides, or glassy particles, and their spatial distribution is also likely to vary as a function of wind direction and distance from the smelter. With time, however, weathering of minerals derived from primary ore or smelter sources in soils might alter or dissolve them and potentially disperse them in the environment. The committee emphasizes that the selection of specific properties to be used for source attribution must be based on physical, compositional, mineralogic, or geochemical differences in the materials that make up the various source materials that need to be distinguished. Furthermore, it might be necessary to use multiple methods to differentiate between sources. In some cases, even with multiple analytic approaches, source identification might not be definitive in distinguishing natural materials from local mined materials or wastes, especially in soils and sediments.

RESEARCH RECOMMENDATIONS

Additional research will provide opportunities to enhance the analytic techniques and methods that make up the committee's proposed investigative strategies and to reduce uncertainty in their implementation. The committee finds that characterizing potential sources has high priority for research and lists below several topics that deserve attention. The research needs are not listed in order of priority.

• *Improved characterization of lead isotopic composition of historical paints.* To evaluate the utility of lead isotopic analysis for distinguishing lead sources, additional study of lead isotopes will be necessary. There appear to be few data on the lead isotopic composition of house paint in Southeast Missouri, and the committee recommends systematic sampling and lead isotopic analysis of paint in houses built before 1980 throughout the Southeast Missouri Lead Mining District. Such study would give a much clearer indication of the lead isotopic composition of paint used in the area and would clarify the degree to which lead isotopes provide a method for attributing some lead sources.

• *Improved characterization of lead-bearing geologic materials and mining wastes.* Because lead isotopic analysis will probably not allow distinguishing natural materials from mining materials or wastes, physical and chemical properties of the latter materials need to be characterized better so that the properties can be used to help to distinguish sources. The goal is to identify fine-scale variability in the sources on the basis of isotopic composition, elemental chemistry, mineralogy, grain size, or texture.

• *Capability to model metal concentrations in soils as a function of depth.* The science of modeling sediment distributions in river floodplains is relatively advanced. In contrast, modeling of metal movement through soils is less developed. Studies could be completed on soils near known metal-emitting sources to map and model how the metals have moved, if at all, through the soils as a function of time.

• *Characterization of size distribution of suspended particles in air samples.* Tailings impoundments, chat piles, and smelter emissions are important sources of airborne lead in a mining district, and little is known about the size of suspended particles and their mobility. Size-selective sampling of air samples in the Southeast Missouri Lead Mining District should be conducted to determine the particle-size distribution. Size-selective sampling can be conducted upwind or downwind of a source, such as a smelter or tailings impoundment, to evaluate contributions from the source.

• *Characterization of source strength of airborne particles from mining wastes.* Little is known about rates of emission of airborne lead from stockpiles of mining wastes. Portable wind tunnels can be used to estimate the airborne particle emission rates and dust production from stockpiles of mining wastes and to measure the threshold wind velocity at a specific site that results in particle suspension and later transport downwind. That information can help to establish whether airborne lead from mining wastes is an important source of lead contamination downwind.

• *Investigation of industrial archeology as a tool for source identification.* Industrial archeology is the systematic study of material evidence associated with historical industrial activity. Although historical industrial processes were generally on a smaller scale than modern industry, they operated less efficiently, were more likely to use processes and materials that produced hazardous byproducts, and lacked pollution controls. An understanding of historical practices could shed light on their relative

Copyright National Academy of Sciences. All rights reserved.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

importance as a source of legacy pollution that persists long after the industries have disappeared.

Although the committee was not asked to identify possible exposure pathways or methods for determining which lead source at a contaminated site might be the most important for human exposure, it did consider whether its investigative approaches could help to answer such questions. Blood lead is often used as a measure to determine whether (and how much) lead exposure has occurred. The committee's recommendation for using lead isotopic analysis also applies to investigating sources of blood lead. Although additional study would be needed to determine where and under what conditions lead isotopic analysis could provide unambiguous lead-source attribution for people who have high blood lead concentrations, the approach appears promising for the Southeast Missouri Lead Mining District and possibly other mining districts, such as Coeur d'Alene, Idaho.

Introduction

In 1980, Congress passed the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), which established the Superfund program to address environmental contamination in the United States. As part of the Superfund program, the US Environmental Protection Agency (EPA) conducts site investigations, determines whether a site needs to be remediated, and attempts to identify parties who are responsible for the contamination and thus financially responsible for the remediation activities. Identifying potentially responsible parties is often difficult because sites can have a long history of use and involve contaminants that have many potential sources. That is often the case for sites that involve metal contamination; metals occur naturally in the environment, they can be contaminants in the wastes generated at or released from a site, and they can be used in consumer products, which can degrade and release the metals into the environment. Lead as an environmental contaminant associated with sites at or near lead-mining districts provides a primary example of the complexities that are involved in identifying potential sources. Lead occurs naturally in the environment, is present in wastes associated with lead-mining districts, and has been used in various consumer products that are known to have resulted in environmental contamination, such as leaded gasoline and paint. Given the complexities surrounding lead contamination, Congress asked EPA to commission a study by the National Academies of Sciences, Engineering, and Medicine to examine the extent to which various sources contribute to environmental lead contamination at Superfund sites that are near lead-mining areas. Accordingly, the National Academies convened the Committee on Sources of Lead Contamination at or near Superfund Sites, which prepared this report.

SUPERFUND PROGRAM

As noted, the Superfund program was established to address human-health and environmental risks posed by abandoned or uncontrolled hazardous-waste sites. CERCLA gave EPA the resources and authority to clean up sites and seek reimbursement from potentially responsible parties. The Superfund process begins with the identification or notification of a potentially hazardous release and involves several steps, which are described in Box 1-1. If EPA's investigation results in listing of a site on the National Priorities List (NPL), the site is eligible for cleanup under the Superfund program. As of March 2017, 1,337 sites were listed on the NPL (EPA 2017a). They include manufacturing plants, processing facilities, landfills, and mining sites and involve a wide array of contaminants. Some of the most complex sites are mining sites not only because of their size but because their contaminants can have multiple possible natural and anthropogenic sources; this is problematic when one is trying to identify contaminant sources and assign financial responsibilities for remediation activities. Appendix A provides information on the challenges of obtaining information that can help to determine financial responsibilities.

SOUTHEAST MISSOURI LEAD MINING DISTRICT

As noted, mining sites are typically large and complex, and the Southeast Missouri Lead Mining District provides a prime example of the complexities that a site might pose. It is composed of three large subdistricts—the Old Lead Belt, Mine La Motte–Fredericktown, and the Viburnum Trend—and several smaller ones (see Figure 1-1; Seeger 2008).[1] The area has a long history of lead mining that began in the early 1700s and continues today (Seeger 2008). Until the 1860s, the majority of mining was accomplished by digging shallow pits and extracting the ore near the surface (Buckley 1909; Seeger 2008). Mining practices changed dramatically in the 1860s; the Saint Joseph Lead Company was formed in 1864, and the diamond drill bit was introduced in 1869 (Bonne Terre

[1]The committee notes that considerable lead was also produced in the Washington County barite district in the same region.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

News 2008; Mugel 2017). Those events led to extensive underground mining in the area and the development of a complex of mines in the Old Lead Belt that were 200–300 feet deep and connected by over 250 miles of underground railroad (Seeger 2008). Mines in the Old Lead Belt were finally closed by the early 1970s because the higher-grade ore had been exhausted. At that time, the large and recently discovered deposits of the Viburnum Trend were coming into production (MO DNR 2017). Today, the only active mining in the area is along the Viburnum Trend, from which Missouri continues to supply most of the US primary lead with byproduct zinc, copper, and silver (Guberman 2014).

The mining sites typically included milling operations in which the ore was processed and the lead-bearing minerals were extracted. There were also smelting operations in the area that converted the lead from its mineral form to its elemental state. Waste materials were generated in processing the ore, and in the early years a density separation process was used and generated a coarse waste material often referred to as chat that was accumulated in enormous piles at the milling sites (ATSDR 1996, 1998). In the later years, a finer grinding of the ore allowed a more efficient separation process (flotation) to extract the lead minerals while generating much finer waste mate-

BOX 1-1 Steps in the Superfund Assessment Process

Site Assessment: The first phase of the Superfund process includes the *preliminary assessment* and *site investigation* in which EPA gathers the site history and analyzes air, water, and soil samples to determine the risk that the site might pose to people or the environment. The data collected al-low EPA to determine whether any immediate action should be taken to protect public health or the environment and to calculate a score by using its hazard ranking system (HRS), which helps to determine whether the site should be listed on the NPL.

NPL Listing Process: This process is started if the HRS score indicates that the site should be included on the NPL and includes an announcement and public-comment period regarding a potential listing of the site on the NPL. Once the comments have been reviewed and evaluated, EPA determines whether the site should be listed. The NPL contains the worst hazardous-waste sites that require extensive cleanup measures.

Site Characterization: This stage is undertaken if a site is listed on the NPL. It includes a *remedial investigation* in which numerous samples of air, surface water, groundwater, sediment, soil, waste, and biota are taken and analyzed to determine the specific risks associated with the site. A *feasibility study* outlines possible options for cleanup and discusses costs, advantages, and disadvantages of each option. A proposed plan for cleanup is developed and announced, and public comment is sought.

Record of Decision: A record of decision contains the final decision regarding cleanup measures. It provides information on "site history, site description, site characteristics, community participation, enforcement activities, past and present activities, contaminated media, the contaminants present, description of response actions to be taken…the remedy selected for cleanup…[and] consideration of how the site could be used in the future."

Remedial Design and Remedial Action: The next phase of the process includes the development of specific engineering details concerning cleanup measures and the process of undertaking cleanup.

Construction and Post-construction Completion: Construction completion is the signal that all physical cleanup activities have been completed. Post-construction activities can be initiated, such as site monitoring that is required to ensure public and environmental safety.

NPL Deletion: The site is considered for deletion from the NPL when cleanup is considered complete and the site is no longer judged to pose a risk to people or the environment. An announcement is made concerning the delisting, and public comment is sought. After reviewing and evaluating the comments, EPA determines whether the site should be removed from the NPL.

Reuse: The goal of the Superfund process is restoration of a site to productive industrial, commercial, residential, or recreational use.

rials, known as tailings, that were pumped into settling ponds or impoundments (ATSDR 1996, 1998). The committee notes that mining waste or residual material from processing is typically referred to as tailings; however, the term *chat* is also used in the Southeast Missouri Lead Mining District to distinguish between coarse and fine waste material. Mining operations are discussed further in Chapter 2.

Some areas in Southeast Missouri are contaminated with lead, and several areas in St. Francois, Madison, Jefferson, and Washington Counties have been designated as Superfund sites (EPA 2017c). Determining the sources of lead at the sites, however, is complex. First, the area is rich in naturally occurring lead-ore deposits that are at or near the surface. Second, the area has a long history of mining activities. Third, an enormous amount of waste has been produced as a result of all the mining activities. For example, an estimated 250 million tons of tailings were generated from mining activities in the Old Lead Belt (ATSDR 1996, 1998). Some of the tailings have been redistributed from their original disposal sites by natural forces, such as wind and rain, and there has been intentional transport of

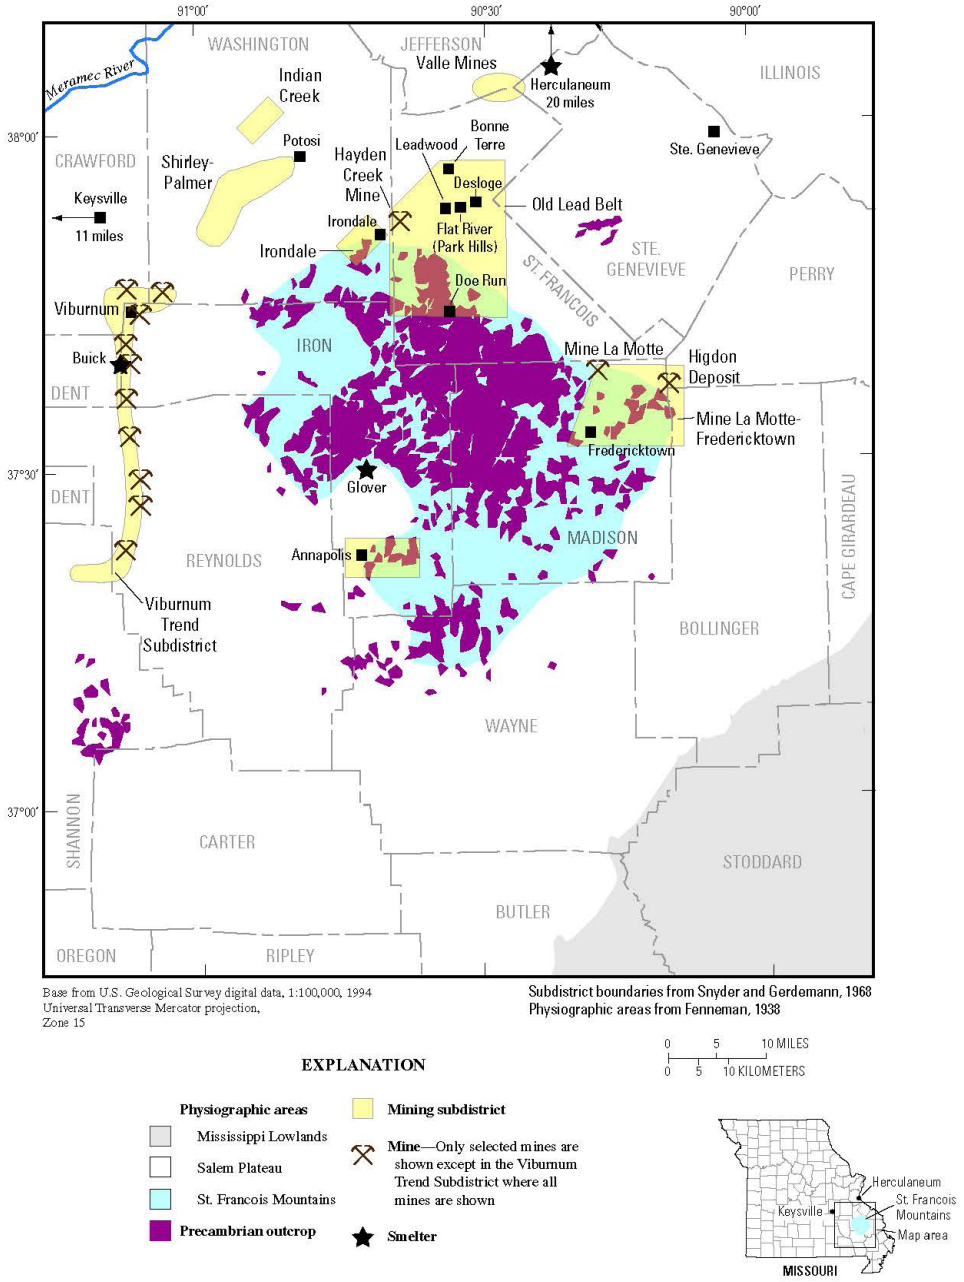

FIGURE 1-1 Southeast Missouri Lead Mining District. Source: Seeger (2008).

Copyright National Academy of Sciences. All rights reserved.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

chat and other byproducts offsite (ATSDR 1996, 1998). Specifically, the tailings were sold as agricultural lime, used as fill material, incorporated into asphalt, and used to treat roads (Meyers 1989; ATSDR 1996). There are even anecdotal accounts of the tailings being used for children's sandboxes (Lee 2006). Fourth, the picture is complicated by the long history of use of lead in consumer products, such as paint and gasoline. Thus, lead at a site could result from naturally occurring deposits, from historical mining activities, from current mining activities, from consumer products, or from some combination, and identifying the sources becomes problematic.

THE COMMITTEE AND ITS TASK

The committee that was convened as a result of the agency's request included experts in aqueous and soil geochemistry, economic geology, environmental fate and transport, lead-source characterization, environmental data analysis, risk assessment, and Superfund policy. Appendix B provides biographic information on the committee members. As noted, the committee was asked to examine the extent to which various sources contribute to environmental lead contamination at Superfund sites that are situated near lead-mining areas and to focus specifically on sources contributing to lead contamination at sites near the Southeast Missouri Lead Mining District. The committee's verbatim statement of task is provided in Box 1-2; it is important to note that the committee was not asked to identify human exposure pathways.

THE COMMITTEE'S APPROACH TO ITS TASK

To accomplish its task, the committee held five meetings. During its first two meetings, the committee held open sessions to hear from the sponsor, mining-industry representatives, and regional scientists from the US Geological Survey, the Missouri Geological Survey, the Missouri Department of Natural Resources, and the Missouri Department of Health and Senior Services. As part of the second meeting, the committee toured portions of the Southeast Missouri Lead Mining District to gain a better appreciation of the natural geology and geography, the mining and tailings sites, and the remediation activities. Appendix C contains the agendas of the open sessions. The committee reviewed numerous scientific publications and all materials submitted to it from outside parties.

The committee interpreted its task as a request for investigative strategies that could provide the evidence needed to identify lead sources in various environmental media. It did not consider its task to be determining lead sources; such an activity would require extensive sampling, analysis, and interpretation that the committee was not equipped to perform. As directed, the committee focused its efforts on whether sources of lead in the Southeast Missouri Lead Mining District could be distinguished by using various analytic techniques. The committee emphasizes that it did not consider exposure pathways, which would need to be considered for identifying which lead sources are contributing to human exposure.

ORGANIZATION OF THIS REPORT

The committee's report is organized into five chapters and three appendixes. Chapter 2 describes possible sources of lead contamination. Chapter 3 describes mechanisms of environmental dispersal of lead, and Chapter 4 proposes investigative strategies for determining sources of lead in various media. Chapter 5 discusses the implications of the committee's strategies specifically for the

BOX 1-2 Statement of Task

An ad hoc committee will examine the extent to which various sources contribute to environmental lead concentrations in areas at or near Superfund sites that are situated within or adjacent to lead-mining areas. The committee will consider whether sources, such as naturally occurring lead, lead-based paint, and the consumer use of products that contain lead, are significant contributors to environmental contamination problems identified through the Superfund site assessment process. In addition, it will consider the extent to which the chemical form of lead in the environmental media can be attributed to particular kinds of sources.

The committee will focus primarily on sources contributing to environmental lead concentrations at or near Superfund sites within or adjacent to the Southeast Missouri Lead Mining District. It also will consider several Superfund sites within or adjacent to other lead mining areas in the United States.

The committee will recommend potential improvements in approaches used for assessing sources of lead contamination at or near Superfund sites, without recommending changes to the clean-up requirements or remediation activities at any designated site. The committee also will identify important research needs.

2

Sources of Lead Contamination

As noted in Chapter 1, environmental lead can have many sources. It can occur naturally or result from mining or other industrial activities or from the production and use of consumer products that contain lead. This chapter describes the various sources that potentially contribute to lead contamination at or near a Superfund site (see Figure 2-1), and Chapter 3 describes the mechanisms by which environmental dispersal might occur.

NATURAL AND MINING-ASSOCIATED MATERIALS

Lead is a widespread, naturally occurring element found throughout the Earth's crust and is commonly enriched in many materials in mining districts. It occurs in virtually all rocks, soils, sediments, and waters at low concentration; however, it can occur at high concentrations over large areas because of natural and human-caused processes. A variety of geologic processes can cause natural lead enrichment, commonly in association with other metal enrichment; in some cases, concentrations of economic interest (ore deposits) are formed. Natural processes that operate at or near the Earth's surface can concentrate lead further or disperse it into the environment. Such processes could include volcanic emissions, forest fires, and various erosional processes. Similarly, human activity, particularly mining of metallic ores, leads to concentration and dispersion (see Figure 2-1).

In most rocks, lead occurs at low concentrations and behaves geochemically like the alkalis and alkaline earths. As such, it is dispersed in common rock-forming minerals, such as feldspars, amphiboles, micas, and sulfates, where it substitutes for potassium, barium, and similar elements (Sahl et al. 1978). At high concentrations, it forms discrete lead-rich minerals, notably sulfides, carbonates, sulfates, and oxysalts (Sahl et al. 1978). Of the roughly 400 lead-rich minerals known (Back et al. 2008), the most common and essentially the only ore minerals are lead sulfide (galena, PbS), lead carbonate (cerussite, $PbCO_3$), and lead sulfate (anglesite, $PbSO_4$). In this section, the committee briefly discusses the types of lead-bearing mineral deposits, the natural distribution of lead, and mining processes that can lead to dispersal of lead in the environment.

Lead-Bearing Mineral Deposits

Many mineral deposits—rocks that contain materials of potential economic interest—and their surrounding materials contain lead in such concentrations as 0.01 to over 10 wt %, which are well above the typical concentrations (5–80 ppm, and usually less than 20 ppm) in rocks and soils found outside mineralized regions (Faure 1998; Smith and Huyck 1999; Rudnick and Gao 2014). As noted above, human activities have led to environmental dispersal of lead; lead concentrations in post-industrial soils and sediments are about 50–100 ppm (Callender 2005), and concentrations at contaminated sites vary widely—up to thousands of parts per million (Gutierrez et al. 2016).

The decision to recover any particular commodity depends on economics, geology, available technology (extraction methods), and other incentives, not simply on the characteristics of the ores themselves. Thus, anywhere from none to most of the lead might be recovered from mined materials. For example, in Southeast Missouri, lead was the primary product from numerous small operations in the Washington County barite district before the 1920s, at which time production of barite became the focus of mining, and lead from that area became a co-product or a byproduct, or was discarded (Wharton 1972; Mugel 2017). Given the various factors that determine whether a commodity is mined, four categories of mineral deposits might be encountered at a Superfund site, as described below.

- Primary lead deposits in which lead is the primary or sole commodity (primary product) that motivates mining. The classic example is the Southeast Missouri Lead Mining District, where the principal value in most deposits is lead.

Copyright National Academy of Sciences. All rights reserved.

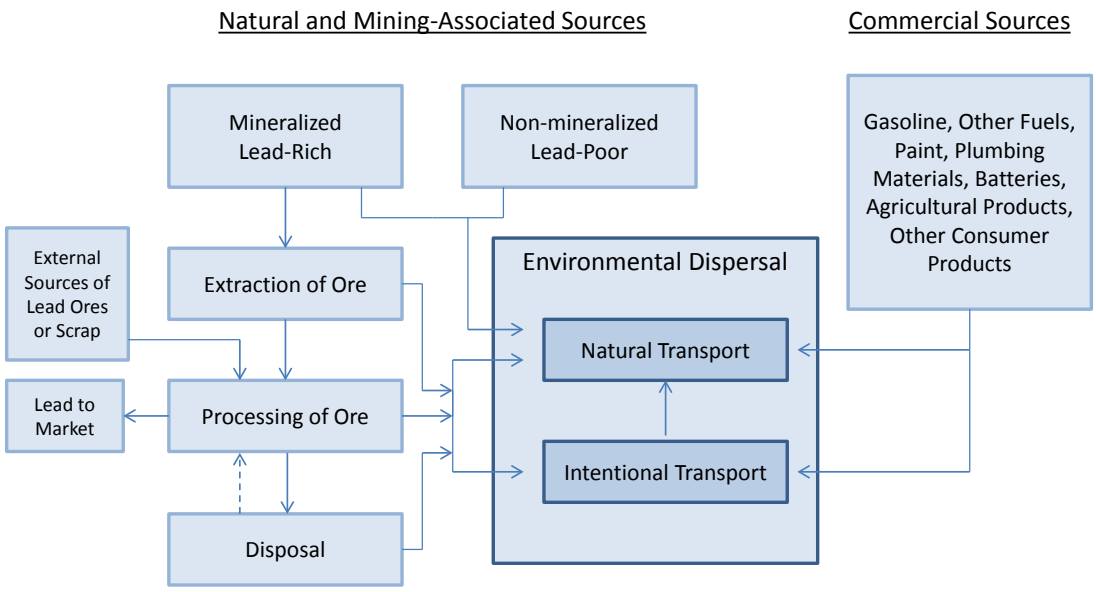

FIGURE 2-1 Natural, mining-associated, and commercial sources can cause lead contamination in the environment through natural or intentional transport. *Natural transport* refers to environmental processes—such as wind, water flow, and soil erosion—that disperse materials; *intentional transport* refers to all human activities that move materials and have the potential for dispersal in the environment.

• Mineral deposits in which lead is a co-product, and its recovery is an essential part of the economics, but production of other metals is also essential. There are a number of examples, including the midcontinent Tri-State district (Missouri-Kansas-Oklahoma), where lead was co-produced with zinc; Coeur d'Alene, Idaho, where most deposits produced lead and silver; and Leadville, Colorado, where lead was co-produced with silver, gold, and zinc.

• Mineral deposits in which lead is recovered as a byproduct because it is economically profitable to do so but not necessary for profitability. Examples include the vein deposits of the Silverton district, Colorado, which include the Gold King, Sunnyside, and related mines that were produced primarily for gold and silver, but where other metals, including lead, were common byproducts.

• Mineral deposits where lead at lower concentrations (commonly less than 0.5%) is mined with the ore but is not recovered. An example is the Ducktown district, Tennessee, which produced copper and iron sulfide (for sulfuric acid).

Metallic mineral deposits form when geologic processes concentrate metals into small volumes of rock from much larger, relatively dilute sources. As in the case of lead, concentrations in ores are typically a thousand times as great as in the source rocks. Lead-bearing deposits form in many geologic settings with a corresponding diversity in ore types and characteristics. The geologic occurrence and the geochemical nature of lead-bearing ores have fundamental effects on how lead gets into the broader environment, whether through natural dispersion or by mining and related human activities (du Bray 1995; Plumlee 1999). The most important lead-bearing deposits and some of their principal characteristics are summarized below.

• *Deposits associated with sedimentary basins*. These deposits constitute the most important lead ores globally and include the Mississippi Valley Type (MVT) ores of the middle of North America (Leach et al. 2005, 2010) and the ores of the Southeast Missouri Lead Mining District. The deposits are typically stratabound (confined to favorable layers), and the rocks that host the deposits are commonly rich in carbonate minerals. The low iron sulfide and high carbonate concentrations of these deposits limit acid production during weathering and thus limit lead solubility and mobility in the surface environment.

• *Deposits associated with hot waters generated from or circulated by magmatism*. These deposits include carbonate replacement, polymetallic veins, and seafloor massive sulfides. They are the most common types of mineral deposits and typically have small to moderate quantities of lead with other base and precious metals (Ridley 2013). They commonly have abundant sulfide minerals, and their host rocks might lack appreciable acid-neutraliz-

Copyright National Academy of Sciences. All rights reserved.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

ing capacity. Thus, lead can be appreciably mobile under these circumstances.

• *Deposits associated with waters circulated during metamorphism*. These deposits are mainly vein gold deposits with relatively low lead concentrations (Goldfarb et al. 2005), although the Coeur d'Alene silver–lead deposits of Idaho fit this category (Ramos and Rosenberg 2012). The moderate sulfide and carbonate mineral concentrations result in moderate acid production and acid-neutralizing capacity.

• *Residual deposits associated with weathering*. Chemical weathering processes can substantially increase the concentration of lead minerals because of removal of other, more soluble components. This situation is common in the weathered zone of many metal deposits and in the clay-rich soils formed on lead-bearing carbonate host rocks, such as in the Washington County barite district, Missouri (Wharton 1972; Kaiser et al. 1987). Acid production is minimal, and neutralization capacity is moderate.

Geologic differences are important because they lead to different environmental consequences, they allow possible fingerprinting of sources, and they influence the choice of mining and processing methods by which lead and other commodities are produced. Among the important ore characteristics are the capacity to produce acid waters when weathered, the content of toxic elements, and the geologic form and hydrologic setting of the deposits (du Bray 1995; Plumlee 1999; Smith and Huyck 1999; Smith 2007). As summarized above, acid production correlates with the abundance of iron sulfide minerals (pyrite, pyrrhotite, and marcasite), whereas acid-neutralizing capacity is highest in carbonate-hosted deposits, such as those of the midcontinent and many igneous-related replacement deposits. Conversely, seafloor massive sulfide deposits and many vein deposits have relatively high sulfide concentrations and host rocks that are poor acid neutralizers, and these characteristics lead to the wide availability of acid and dissolved metals in groundwater and surface waters.

Lead concentrations (and other element concentrations) vary greatly among ore deposit types and within individual deposits or districts (du Bray 1995; Plumlee 1999; Smith and Huyck 1999). Some ore deposits and ore districts have relatively uniform compositions and host rocks (for example, many MVT deposits and districts), but many exhibit strong spatial variation (zoning) in metals, other elements, and the nature of the local host rocks (for example, magmatic-related hydrothermal systems; Ridley 2013). Lead concentrations can span several orders of magnitude, depending on position; for example, ores at Bingham, Utah, ranged from greater than 10% in the carbonate rock-hosted part of the system to less than 0.1% in the igneous rock-hosted copper-rich core. Because the geochemical signatures vary with deposit type and location of a particular ore-forming system, they can be used to aid in the forensic identification of sources.

A particularly useful geochemical variable is the isotopic composition of lead itself (Box 2-1). Extensive study of lead isotopes in ores shows that different deposit types and regions have compositions that reflect the geologic history of the terrain and the processes involved in ore formation (Doe and Zartman 1979). For example, ores of the midcontinent have distinctively high ratios of the radiogenic isotopes of lead (^{206}Pb, ^{207}Pb, and ^{208}Pb) to non-radiogenic, or primordial, lead (^{204}Pb).[1] Such differences have the potential to distinguish geologic sources and even individual districts and deposits (Goldhaber et al. 1995; Sangster et al. 2000). Application of isotopic differences is discussed further in Chapter 4, and case studies are provided in Chapter 5.

Over 200 mining districts in the United States have produced appreciable amounts of lead (Long et al. 1998), and many more have accessory lead minerals. However, the principal lead production has come from only a large handful of districts. The most important are the Mississippi Valley ores of Southeast Missouri and the Missouri–Kansas–Oklahoma tristate district; the vein silver–lead ores of the Coeur d'Alene, Idaho; and various igneous-related polymetallic carbonate replacement deposits of Colorado (Leadville) and Utah (Bingham, Park City, and Tintic). Of those districts, Southeast Missouri (Box 2-2; Figure 2-2) has produced more than the others combined (Long et al. 1998) and collectively contains the world's largest known concentration of lead (Appold and Garven 1999).

Natural Distribution of Lead

When lead deposits form from hydrothermal fluids, the lead concentration rarely terminates abruptly at the edge of an ore body but rather falls off gradually; this is primary dispersion.[2] The original geologic dispersion reflects the facts that ore-forming fluids typically invade a considerable volume of rock and that the metal-trapping (precipitating) process is commonly inefficient (Rose et al. 1979). Such primary distributions can be highly focused, around a few meters or less, if the flow of mineralizing fluids was strongly focused (Barnes and Lavery 1977). In other cases, where fluid flow and conditions for precipitation were not localized, tremendous volumes of rock over large areas (tens to thousands of square kilometers) might contain anomalous metals. For example, minor quantities of galena and sphalerite (ZnS) are widely distributed in the

[1]Radiogenic indicates an isotope that has been created from radioactive decay.

[2]The edge of an ore body is an economic boundary that is influenced by a combination of geologic and technologic factors. In many cases, what might be waste under one set of conditions can become ore under more favorable conditions, or vice versa.

Copyright National Academy of Sciences. All rights reserved.

BOX 2-1 Lead Isotopes: A Tool for Source Attribution

Lead-isotope ratios in geologic materials vary because lead isotopes are produced by the radioactive decay of uranium (U) and thorium (Th) over geologic timescales. ^{235}U decays to ^{207}Pb, ^{238}U decays to ^{206}Pb, and ^{232}Th decays to ^{208}Pb, whereas ^{204}Pb is primordial and has no radiogenic parent. Because of contrasting geologic histories, ages, and U/Pb and Th/Pb ratios, there is a wide range of lead-isotope ratios among lead-bearing ore deposits and other geologic materials (see, for example, Sangster et al. 2000; Faure and Mensing 2004). Lead isotopes are not altered in mining, processing, or manufacturing; thus, ratios of isotopes from a given source are the same whether in natural materials, lead-mining waste, or commercial products (provided that a single source has been used in the manufacturing process). A simple isotope mixing equation describes the lead isotopic composition of lead from mixtures of sources (Faure and Mensing 2004).

Lead-isotope ratios are often reported as $^{206}Pb/^{204}Pb$, $^{207}Pb/^{204}Pb$, and $^{208}Pb/^{204}Pb$, and plots of these ratios give the most complete differentiation between ore deposits and between sources of environmental lead. The full complement of lead-isotope abundances is measured with thermal ionization mass spectrometry and multi-collector inductively coupled plasma mass spectrometry (ICP-MS). However, some studies that use single-collector ICP-MS do not measure the lower-abundance ^{204}Pb (which makes up about 1.5% of total lead) with adequate precision; therefore, to use all available lead-isotope data in the literature, environmental applications of the ratios often use the $^{206}Pb/^{207}Pb$ and $^{208}Pb/^{207}Pb$ ratios or simply the $^{206}Pb/^{207}Pb$ ratio alone for comparisons between lead sources. Sangster et al. (2000) used a statistical analysis to demonstrate that ^{204}Pb was not critical for discriminating between most lead sources.

Numerous studies have used lead-isotope ratios to distinguish between potential sources of lead in soils and atmospheric and household dust (see, for example, Gulson et al. 1981; Graney et al. 1995). A smaller number of studies have included lead isotopic analyses of human blood or urine; that approach has in some cases allowed elimination of some potential sources and in other cases has allowed identification of the sources of lead exposure (see, for example, Manton 1985; Gwiazda and Smith 2000).

BOX 2-2 Geology of Southeast Missouri Lead Mining District

In Southeast Missouri, tremendous quantities of lead are present in flat-lying Cambrian and Ordovician sedimentary rocks (about 450–550 million years old) that surround and lap onto the edges of an ancient island represented by the 1.5-billion-year-old igneous rocks of the St. Francois Mountains (Figure 2-2). Lead and other components—such as barium, zinc, copper, cobalt, and nickel—were added by warm (about 100˚C) saline fluids derived from adjacent sedimentary basins to the south. The largest lead deposits occur in the oldest sedimentary rocks, mainly the Bonneterre Dolomite and underlying Lamotte Sandstone near where they terminated against the older igneous rocks. The yellow-clay soils that developed on the dolomite were enriched in lead; they were referred to as the “bonne terre” by early miners, reported to contain abundant galena in the upper few tens of meters, and attracted preindustrial development (Winslow 1894; McHenry 2006, p. 362). After the 1860s, the Bonneterre ores were hard-rock ores that were mined underground.

In contrast with the majority of the Bonneterre ores, the lead-bearing barite mineralization in the younger rocks of the Potosi Dolomite and overlying formations consists of residual deposits that formed from widespread but low-grade primary sulfide mineralization, which was concentrated by chemical weathering in residual soils. Because of lead’s relatively low solubility, galena and its oxidation products (cerussite and anglesite) remained in the clay-rich soils with similarly insoluble barite (Wharton 1972; Kaiser et al. 1987). Both commodities were readily recovered from numerous shallow mines, many of them open pits across a wide region, which date back into the early 19th century. Early mining and local mining focused on lead, but from the 1920s to the 1980s these residual deposits were mined by industrial methods for barite (MO DNR 2017; Mugel 2017).

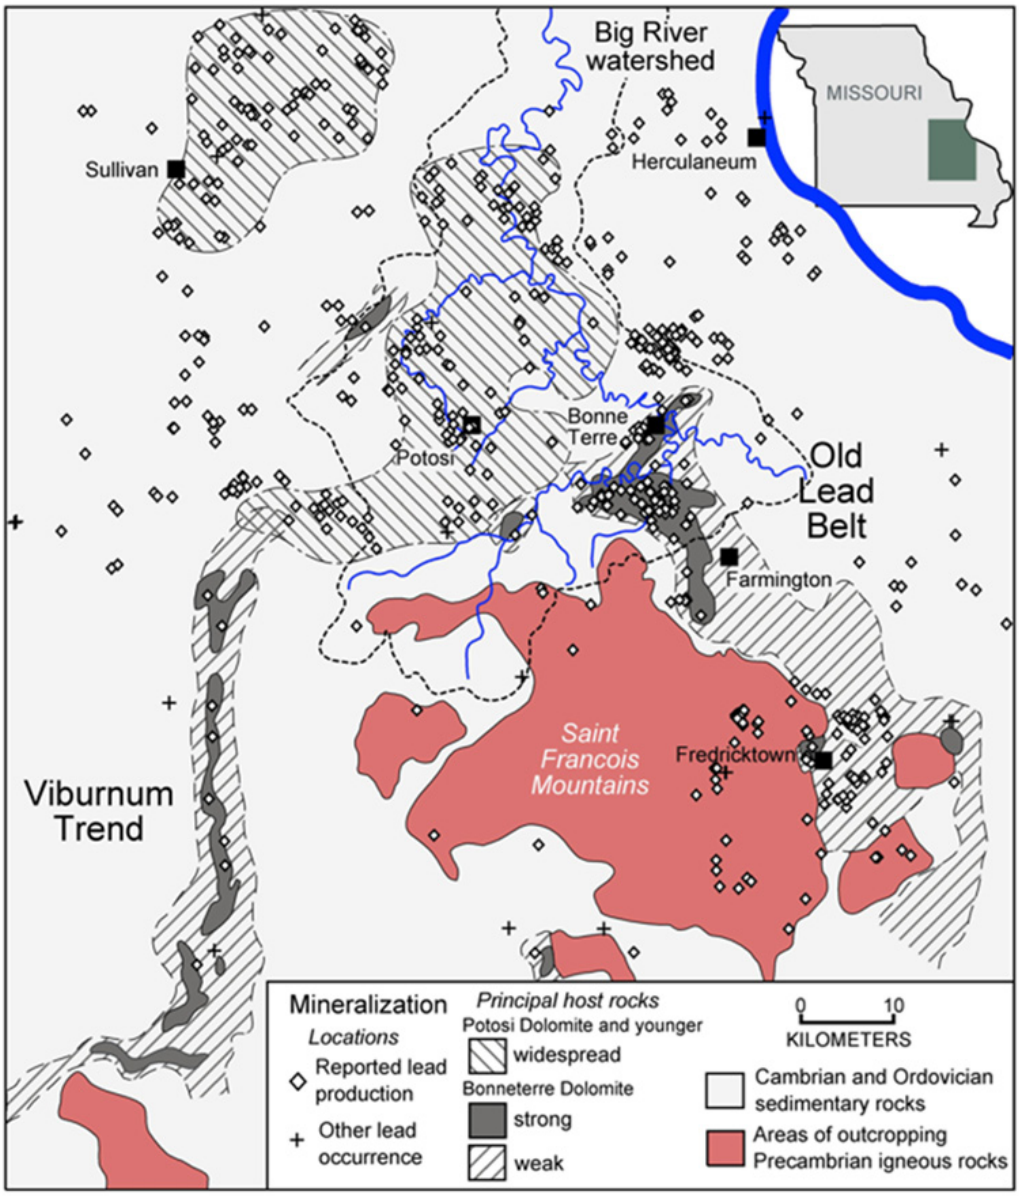

FIGURE 2-2 Distribution of lead mineralization in Southeast Missouri and related features, including the Big River watershed. The thin blue lines are rivers, and the thick blue line is the Missouri–Illinois border. Lead mineral occurrences are from the US Geological Survey Mineral Resources Data System (USGS 2015). High-grade lead mineralization occurs principally in the Bonneterre Dolomite and underlying Lamotte Sandstone, but low-grade lead mineralization is widespread with barite in the residual ores of the overlying Potosi Dolomite and younger formations. Lead mineralization is widely present at the surface in the eastern and northern parts of the region but is essentially restricted to the subsurface along the Viburnum Trend to the west. The boundaries for the Bonneterre-Dolomite mineralization were redrawn from a review by Zientek and Orris (2005), which did not define *strong* and *weak* in the figure inset. However, *strong* appears to refer to regions of mineralization that incorporate areas where there has been substantial lead mining, and *weak* to regions that rarely had any lead production but commonly had lead mineralization in trace quantities.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

Paleozoic sedimentary rocks of the midcontinent, where they represent the sparse products of the metalliferous fluids that flowed regionally along these sedimentary layers (McLimans et al. 1980; Goldhaber et al. 1995; Leach et al. 2005; Figure 2-2).

Weathering and erosion of primary metal concentrations lead to dispersion at or near the Earth's surface. Given the relatively low solubility of lead in most surface fluids, chemical weathering concentrates lead in residual materials in gossans (weathered ores) and clay-rich soils (Rose et al. 1979; Smith and Huyck 1999). The residual materials are ultimately eroded (mechanically removed by running water) and contribute to the overall sediment load in rivers and streams. Only in sulfide-rich deposits that have poor neutralizing capacity is lead dispersed mainly in solution. Environmental dispersal of lead through those various processes is discussed in detail in Chapter 3.

Concentration and Dispersal of Lead by Mining

Lead is concentrated to yield a product but also dispersed by mining (Figure 2-1). Mining begins by physically extracting ore; this is followed by processing of the ore to obtain a concentrate of lead minerals and then by smelting to obtain metallic lead, which is ultimately shipped to market. At each stage, materials are discarded. In the extraction process, waste consists of materials that are moved to mine the ore but that lack economic concentrations of metal. Waste rock can vary greatly in mineralogy, composition, and size. Because the distinction between ore and waste is economic, large volumes of waste can have elevated lead concentrations compared with those of ordinary rocks. Indeed, what is waste under one set of conditions or at one time might be ore in other circumstances, and reprocessing for environmental or economic reasons is common in many long-lived mining districts. Historically, waste disposal was driven by what was easiest; thus, waste was generally discarded in the most efficient manner for the time and place, such as on the surface in dumps or replaced in mine openings. However, by the latter part of the 20th century, waste rock disposal was subject to regulatory controls and handled systematically in a mine's plan of operation.

Processing of lead-bearing ores typically involves physical separation as is the case with all lead minerals. However, some lead-bearing ores might be chemically processed; for example, a cyanidation process is used to treat lead-bearing gold deposits. Tailings are the residua of mineral processing after much of the valuable content has been removed in the form of a concentrate. The efficiency of concentration reflects available technology and economics, and recovery of valuable components can vary from less than 50% to 95%. For example, early and primitive techniques used hand-picking or simple gravitational separation with rockers to upgrade the content of the valuable fraction of the ore; the techniques were inefficient and often resulted in less than 50% recovery, and the balance went into the mine waste or tailings (Mugal 2017). Given the high lead content of ores, tailings typically contain lead concentrations of a few hundred to thousands parts per million, depending on recovery efficiency.

Most mineral processing depends on the characteristic properties of ore minerals that allow separation of the valuable constituents from the unwanted minerals, for example, by using density or distinctive surface properties. Gravity-based methods operate by separating dense ore minerals—such as galena, cerussite, and barite—from a less-dense waste fraction. If the lead-bearing materials are not consolidated, as is the case in residual ores, simple washing and gravity separation might suffice. For example, such methods were widely used in the barite-lead districts of Southeast Missouri, notably in Washington County. In that case, the efficiency of recovery depended on the main product—barite or lead—and, in many cases, a substantial fraction of lead was not recovered and thus discarded in the tailings. See Box 2-3 for additional information on the history of lead mining in Southeast Missouri (Wharton 1972; Mugal 2017).

In hard-rock mining, ores require crushing (milling) to liberate the valuable minerals from the unwanted gangue (waste) minerals. The degree of crushing depends on the nature of the ore, particularly on the grain size of the ore minerals. Except in unusually coarse-grain ores, efficient separation (for example, greater than 90%) commonly requires crushing to fine sand or smaller. How finely to crush the ore is a tradeoff in cost vs recovery. After the ore is milled, the ore minerals are separated from the waste to make an ore concentrate. Gravity separation is still commonly applied, but most sulfides are recovered through selective froth flotation. In froth flotation, hydrophobic surfactants specific to particular minerals are added to a slurry of the crushed ore. When air is bubbled through the slurry, the surface-coated minerals attach to the air bubbles and float to the surface. The metal-laden froth is continuously removed and dried to leave a high-grade mineral concentrate. The concentrate is the feedstock for the final steps in metal production.

Tailing characteristics—such as mineralogy, grain size, and chemical composition—reflect differences in processing, economics, and the broad social and regulatory environment. Over time, tailings disposal has seen an increasing focus on engineered impoundments. In recent decades, designed and built impoundments control not only the bulk tailings themselves but their potential water and dust effects. Early mining operations paid little or no attention to disposal methods; often, there was no effort at impoundment, and some tailings were discarded directly into streams. With time, tailings were typically discarded in designated areas, but often the areas were not designed

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

to control slope failure, other types of erosion, wind effects, and water discharges.

The final steps in the recovery of lead are broadly termed smelting; they reflect conversion of the ore concentrate into metal and various waste products, including slag, gases, and dust (Vignes 2013). Smelter feed can include both primary sources (concentrates) and secondary sources (from recycling). As smelters became larger industrial operations through the 20th century, their feedstock evolved from local sources (one or more nearby mines) to a mix of sources.

Depending on the nature of the feed (recycled metals or ore concentrate), the smelting process begins with pretreatment that might include mechanical separation (secondary sources) or drying, calcining, or roasting (primary sources). The materials are then smelted and converted to metal by reduction from the sulfide or oxide form. The molten waste product (slag) contains iron, silica, calcium, some residual metal, and other minor components. Sulfide smelting involves passage of gases that carry off the sulfur, mainly as sulfur dioxide. The emitted gases also contain appreciable amounts of particulate matter in the form of melts or solids. As with mine waste and tailings, early smelting operations were typically inefficient and operated with no emission controls. Gases, slag, and dust were discharged directly into the environment. In more recent times, particularly with the passage of the Clean Air Act and resulting regulation, smelter emissions have been greatly reduced by treatment of sulfur-bearing gases and by control of dust and other particles. Slag is typically disposed of in heaps, where it is poured, cools, and solidifies. Ultimately, the metals produced by smelting might be further processed in a refinery to recover precious metals (notably silver in the case of lead) or to remove impurities that are not wanted in the final salable product. Like the earlier stages, solid and liquid refinery wastes have had a checkered history of disposal and might still contain appreciable metals. After smelting and mining, lead is distributed to other regions where it is converted into manufactured or chemical products, providing other opportunities for lead dispersion in areas that are typically well outside mining areas.

OTHER SOURCES OF ENVIRONMENTAL LEAD

There are possible sources of environmental lead in addition to natural sources and those associated with mining (Figure 2-1). Indeed, the 2014 National Emissions Inventory estimated that less than 1% of atmospheric lead emissions in the United States was the result of mining activities (Table 2-1). Mining-related emissions of lead in Missouri accounted for one-third of the national mining-related emissions but only 10% of the total lead emissions in the state. This section briefly discusses other sources of lead that could contribute to environmental contamination.

BOX 2-3 History of Lead Production in Southeast Missouri

The history of lead production in Southeast Missouri illustrates the challenges in attributing sources of lead to mining compared with other sources (MO DNR 2017; Mugel 2017). Early mining and smelting techniques were primitive; surface disturbance was extensive, and there were many local smelting operations. Lead minerals were recovered by hand, including primitive gravity separation techniques, and losses ranged from as little as 10% to greater than 50% of the total contained lead, which then ended up in mine waste and primitive tailings. Cerussite and galena were smelted locally with a series of open-air techniques that also failed to recover tens of percent of the lead contained in the ore mineral concentrates.

As noted in Chapter 1, industrial-scale mining began in the 1860s with development of the major underground ore bodies in the Old Lead Belt (Figure 2-2), but considerable small-scale surface mining continued by local landowners through the 1930s. Conversion to barite mining in the 1920s in the Washington County barite district was accompanied by a shift from largely local operations for lead to industrial-scale production of barite, which led the world in barite production for decades (Wharton 1972). High-grade ores in the Old Lead Belt were gradually exhausted with the last mine closing in 1972. By that time, the Viburnum Trend, or New Lead Belt (Figure 2-2), was in full production. Those ores, which are completely covered by younger rocks, were discovered in 1955, and the first production was in the middle 1960s. In contrast with the other areas in Southeast Missouri—where there was a century or more history of mining, processing, and smelting—the industrial-scale operations of the Viburnum Trend were developed in a far more consolidated manner with designed mine-waste dumps and tailings impoundments. In parallel with mining and milling, smelting operations were progressively more centralized, and smaller operations closed. The last primary smelter, at Herculaneum, Missouri (Figure 2-2), closed in 2013, although the Doe Run Company continues to run one of the world's largest secondary lead smelters for recycling of lead-acid batteries and other scrap at Boss, Missouri.

Gasoline and Other Fuels

In the United States, lead has been added to gasoline and other fuels since 1929 to prevent engine knocking. Mielke (1999) estimated the total consumption of lead in gasoline in the United States from 1929 to 1986 as 5.9×10^6 metric tons. The use of alkyl–lead additives in automobile fuels has been nearly eliminated since US Environmental Protection Agency (EPA) promulgated guidelines in the 1970s that mandated that new cars run on unleaded gasoline. The sale of leaded automobile fuels was discontinued in 1986, although a small amount of alkyl–lead continues to be used in racing sports and by owners of classic cars. The sharp decline in lead consumption in gasoline (Figure 2-3) resulted in a 98% decrease in total national lead emissions from 1970 to 1995 (EPA 2013).

Alkyl–lead additives are still used in aviation fuel, specifically for small piston-engine aircraft. Although emissions that result from the operation of those airplanes was a tiny fraction of total atmospheric lead emissions in most of the 20th century, they accounted for more than half the national lead emissions by 2008 (Rao et al. 2013) and for nearly two-thirds in 2014 (Table 2-1). Aircraft-related lead emissions are highly variable; areas near airports experience the highest loadings.

Although automobile-related lead emissions are now near zero, the legacy lead that remains in soils and sediments is a potentially important lead source at or near Superfund sites. Smith (1976) found that lead concentrations in the top 5 cm of roadside soils were up to 30 times the concentrations in soils away from the roadside. Emissions of gasoline lead, however, were widely dispersed around the country and resulted in deposition and accumulation of lead in soils and surface waters even in remote areas. Johnson et al. (1995) estimated that the total lead deposition in precipitation at the Hubbard Brook Experimental Forest in New Hampshire in 1926–1989 was 8.66 kg/ha. Because Hubbard Brook is remote from point sources of lead pollution, the lead deposition was interpreted as an estimate of gasoline-lead input into the forest. Lead is readily adsorbed in soil organic matter and clay particles (see Chapter 3), so nearly all the lead remains in the soil and makes up a large fraction (about 10%) of total lead in the soil (Johnson et al. 2004). At Hubbard Brook, the mass of the O soil horizon (surface soil layer), where most of the atmospherically deposited lead is stored, is 8.7 kg/m^2 (Johnson et al. 1991); thus, gasoline lead might account for up to 100 ppm of the total lead in the O soil horizon. Furthermore, the 1926–1989 atmospheric lead input was similar in magnitude to that of total lead released from soil minerals by chemical weathering in the 12,000–14,000 years since the last glacial retreat. The burden of gasoline-derived lead in soil can thus be quantitatively important in studies aimed at lead-source apportionment.

Paint

The use of lead in paints in the United States dates back to the colonial era. White lead provided a consistent base color for interior and exterior paints and made the paint more durable and easy to wash (Browne 1930; Hallett and Rose 1935). Widespread use of lead in US paint manufacturing began in 1884 and peaked in the 1920s,

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

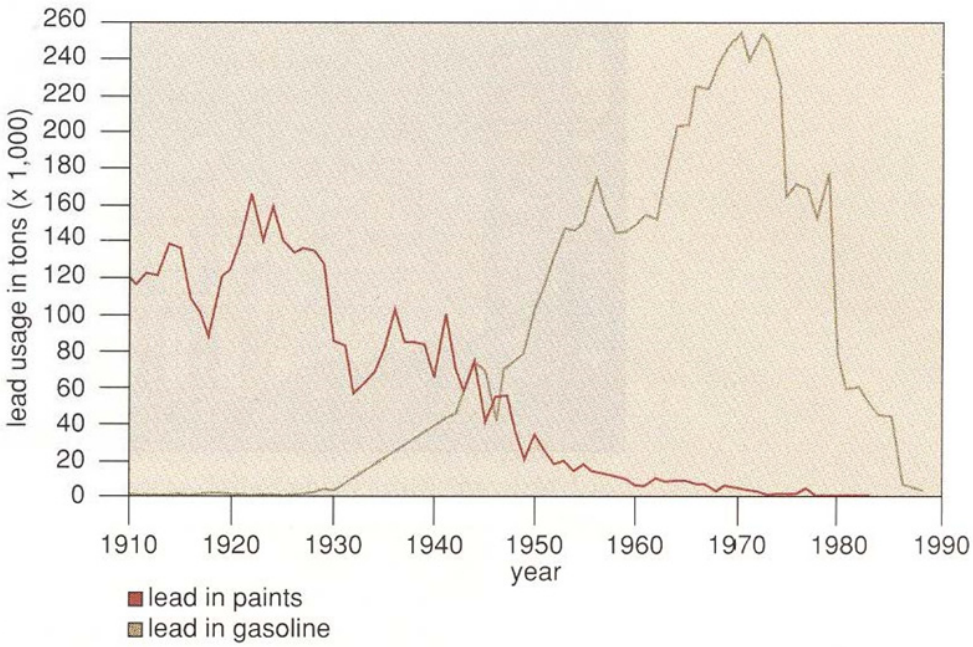

FIGURE 2-3 Annual consumption of lead in the United States in paint and automobile gasoline. Source: Mielke (1999). Reprinted with permission; copyright 1999, *American Scientist*.

but lead-based paints continued to be widely used, especially on exterior surfaces, into the 1970s (Figure 2-3). Baltimore, Maryland, passed the first municipal law that banned the use of interior lead paints in 1951. In 1978, the federal government banned the sale of all lead-based paints. The total consumption of lead by the US paint industry was similar in magnitude to that used in gasoline additives for automobile fuels (Mielke 1999). Therefore, as with gasoline, old paint could represent a quantitatively important source of lead in some soils.

Because of the durability of lead paints and the tendency to paint over, rather than remove, previous paint layers, a large amount of lead is associated with older buildings and with construction debris. Chipping, physical abrasion, and breakdown of paint surfaces by atmospheric chemicals, such as ozone and nitrogen dioxide (Edwards et al. 2009), lead to the release of particulate, aerosol, and gaseous lead from interior and exterior surfaces of residential, commercial, and industrial structures. Soils near buildings constructed before the 1970s often have high lead concentrations, especially near the drip lines where water runs off rooftops. In an extensive study in New Orleans, lead concentrations were substantially higher in soils collected along drip lines of residential homes than in soils near streets or in parks (Mielke 1994; Mielke and Reagan 1998).

Paints used for road markings have also historically contained lead. Abrasion of those paints by vehicles results in road dust with high lead concentrations, much of which is deposited along the sides of the road (Murakami et al. 2007). Some oil paints used by artists continue to contain lead.

Plumbing Materials

Lead pipes were used extensively in indoor plumbing and for residential service lines in most American communities well into the 20th century. Most municipal building codes now prohibit new installations of lead piping, but many homes and older buildings still have lead risers inside and lead service lines outside. In some municipalities—notably Flint, Michigan—lead service lines deliver large amounts of the domestic water supply. Furthermore, lead solder has been used to join copper pipes and pipe fittings and might also be a source of lead in domestic plumbing systems. Corrosion and chipping of the pipes are potential sources of lead contamination in drinking water and in soils outside residential and commercial buildings.

Demolition of aging buildings can result in large releases of lead into the environment if lead pipes and other building materials that contain lead are not removed. Construction debris is thus an important source of lead in many reclaimed urban sites. Superfund sites associated with industrial activities dating back to the first half of the 20th century or earlier might thus have substantial stocks of lead from plumbing and building materials.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

Batteries

The manufacture of batteries is one of the largest industrial uses of lead globally. The lead-acid ($Pb–PbO_2$) battery remains the standard means for generating electricity in most vehicles. In the United States, there is an efficient recycling program for lead-acid batteries of all types, which has greatly reduced the amount of battery lead released into the environment generally and deposited in municipal landfills specifically. Smith (2004) estimated a recycling efficiency of 95% for lead in batteries in the United States. The domestic recycling efficiency was estimated to be 77% owing to the export of spent batteries (primarily to Mexico) for recycling. Papp (2013) used a different accounting approach and reported a similar value of 81% for 2011. Wilburn (2014) estimated that 95.5% of the mass of lead-acid batteries was recovered from the municipal waste stream in 2000–2010.

Estimates of lead recycling do not account for long-term storage of batteries before recycling. Substantial lead release can occur from batteries experiencing corrosion. Battery lead might thus be an important source of contamination at sites that host automotive repair businesses.

Agricultural Amendments

Mining wastes have been used as agricultural amendments because metals are commonly associated with carbonate or phosphate rocks (Davies et al. 1993). In the Southeast Missouri Old Lead Belt, for example, chat left over from the extraction of lead from the Bonneterre limestone was crushed and sold for use as agricultural lime through much of the 20th century. Much of that material was used in the surrounding region, but some was shipped by train and barge to towns and ports along the Mississippi River.

Pesticide use has also contributed to environmental contamination with lead. Arsenicals were widely used as pesticides and insecticides in the United States until they were banned in 1988. Lead arsenate—$PbHAsO_4$ or $Pb_5(OH)(AsO_4)_3$ (EPA 1986)—is believed to have been the most commonly used arsenical pesticide (Peryea 1998). It was used for a wide array of crops, but its use in orchards, especially for grapefruit and apples (EPA 1986; Peryea 1998), was particularly widespread. Lead arsenate was typically applied by handgun spraying, and application rates depended on the crop species and the target pest (Peryea 1998).

Extensive use of lead arsenate in orchard lands has necessitated remedial action when those lands have been reclaimed for residential use. Schooley et al. (2008) highlight cases from Virginia, North Carolina, Washington, New Jersey, and Wisconsin in which soil lead concentrations of up to 800 ppm were observed in former apple orchards. Contamination at pesticide manufacturing sites has also been documented. The Industri-plex Superfund site in Woburn, Massachusetts—the site of a former chemical plant that made arsenate pesticides—contained soils contaminated with lead, arsenic, and other metals (DOJ 2012). Ayuso et al. (2004) were able to use lead isotopic analysis to characterize the isotopic signature of lead-arsenate pesticides and concluded that the use of these products could be an important source of lead in soils of formerly agricultural lands in New England.

Other Consumer Products

Lead is an important component of a number of consumer products. Perhaps most notable is ammunition for firearms. Lead shot was nearly ubiquitous until the early 1990s. In 1991, its use in waterfowl hunting was banned. In January 2017, the use of lead shot on federal wildlife refuges was also banned—a regulation overturned in February 2017. The burden of lead in soils and wetlands in or near shooting ranges and popular hunting sites can be high enough to be a threat to wildlife, especially waterfowl and raptors (Kendall et al. 1996; Fisher et al. 2006). Lead sinkers can also be an important source of lead in lakes and rivers that are frequented by fishermen (Jacks et al. 2001; Scheuhammer et al. 2003).

Lead-containing toys, jewelry, and decorative arts are other potential sources that could be important in residential areas. Antique toys and toys that are imported from countries where the use of lead paint is permitted are particularly likely to have high lead concentrations. In some cases, the lead is found in the paint used to decorate the toys. Lead might also be incorporated into the plastics of inexpensive toys. Because lead helps to make plastic more malleable, it is likely to be found in soft plastic toys. Similarly, other household plastics, such as vinyl window blinds, can be an important source of household lead. Sunlight and heat can degrade the material and result in release of dust that has high lead concentrations (EPA 2016). In older homes, lead might also have been used in counterweights in windows.

Lead is abundant in several forms of glass. Leaded glass, which is used for artisan crystal and stained glass, is composed of 12–60% lead oxide, and opal illumination glass contains an average of 3.0% lead oxide (Spinosa et al. 1979). In the late 19th and early 20th centuries, Southeast Missouri hosted an active glass industry, including extraction of local sand for glass-making (Burchard 1907). Many glazes and solders have high lead concentrations. Leaded glazes are used because they provide a smooth finish that highlights bright colors. Terra cotta pottery from Latin America, such as Mexican bean pots, often has high lead concentrations, as do some highly decorated ceramics from Asia. Lead solder is often used in electronic parts and in inexpensive jewelry, and lead is used to make jewelry heavier.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

The interested reader is directed to Tables 3-3 and 3-4 in EPA (1998), which contain comprehensive lists of industrial and commercial uses of lead alloys and lead compounds, respectively. Lead derived from the decay of consumer products or present in demolition debris is a potential source to consider in attribution studies in lead-contamination investigations, especially those associated with exposures in the residential environment.

Environmental Dispersal of Lead

Chapter 2 described many possible sources of lead that could cause environmental contamination. To assess whether a lead source might be contributing to observed contamination, one must first consider possible dispersal pathways. As shown in Figure 2-1, there are natural and intentional transport mechanisms; in this chapter, the committee discusses those mechanisms and how they might promote the dispersal of lead into the environment. Aqueous processes and transport are described first, then air transport, and finally intentional transport.

AQUEOUS PROCESSES AND TRANSPORT

A primary natural transport mechanism is water. In this section, the committee discusses lead solubility and species in water, lead partitioning between water and solid phases, and sediment-associated dispersal in rivers.

Lead Solubility and Species in Water

Dissolved lead concentrations can vary by orders of magnitude but are generally lower than those of other dissolved species. In uncontaminated fresh and saline waters, concentrations typically range from around 0.2 to 200 ppt (about 10^{-12}–10^{-9} mol/L). In contaminated waters, lead concentrations typically rise into the range of a few hundred parts per billion (about 10^{-6} mol/L). For example, a river contaminated by acid mine drainage and dissolved metals had a maximum lead concentration of 698 ppb (3.4×10^{-6} mol/L) and a mean concentration of 121 ppb measured over 2 years (Nieto et al. 2007); in contrast, mine runoff and discharge waters at near-neutral pH in a lead mining area had lead concentrations that averaged 2.6–14 ppb over 1.5 years (Schaider et al. 2014). For comparison, in a 7-month period in 1966-1967, the mean total lead concentration in rainfall in the United States was 34 ppb, and lead concentrations were higher near cities because of emissions from industrial activities and gasoline (Lovering 1976). As a result of lead accumulation in soils related to lead-containing precipitation before 1976, lead concentrations as high as 330 ppb were measured in runoff water from soils in some parts of New England (Hem 1976). In the United States, emissions of lead to the atmosphere and later deposition on land decreased substantially after the early 1980s, when the addition of lead to gasoline was phased out (Callender 2005). In highly contaminated surface waters and groundwater, lead concentrations can exceed 1,000 ppb (or 1 ppm), but this is generally rare, and most waters with high dissolved lead have concentrations well below parts per million. Away from contamination sources, lead is typically reduced to low concentrations by mixing and dilution with uncontaminated waters and by adsorbing to particles in the water column as described in the next section.

In most surface environmental settings, the lead in water is predominantly divalent lead, Pb^{2+}. In the absence of dissolved organic matter, Pb^{2+} has a strong tendency to form hydroxo species, such as $PbOH^+$, in solution with increasing pH (Figure 3-1A). In common surface waters and groundwater, the dissolved carbonate is typically about 10^{-5}–10^{-3} mol/L total carbonate, and lead-carbonate complexes will dominate over lead-hydroxo species over the typical pH range of natural waters, about 6.5–9.5 (Figure 3-1B). In contaminated waters that contain high dissolved sulfate, such as those associated with acid mine drainage, free Pb^{2+} is the dominant species below a pH of about 7, and the aqueous complex with sulfate, $PbSO_4(aq)$, is a minor species (Powell et al. 2009). In seawater and high dissolved-chloride systems, lead-chloride complexes—$PbCl^+$, $PbCl_3^-$, and $PbCl_2(aq)$—dominate over free Pb^{2+} below a pH of about 7.5. At alkaline pH and high chloride, dissolved lead is present mostly as aqueous lead-carbonate complexes, $PbCO_3(aq)$ and $Pb(CO_3)_2^{2-}$, rather than free Pb^{2+} or mixed carbonate-chloride and carbonate-hydroxo complexes (Powell et al. 2009).

Dissolved organic matter (DOM) forms strong complexes with Pb^{2+} that can dominate speciation in water, depending on the DOM concentration (Town and Fillela 2000a,b; Rozan et al. 2003). Because natural DOM is a heterogeneous and complex mixture that contains dif-

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

ferent organic functional groups, many binding-site concentrations and stability constants for lead complexation have been reported (Town and Fillela 2000b). Researchers have attempted to use simple organic acids and ligands as proxies for DOM to describe lead–DOM interactions, but those attempts have had mixed success (Rozan et al. 2003; Vega and Weng 2013; Stockdale et al. 2015).

As discussed in the next section, lead can also be transported in surface waters or groundwater in association with colloidal or suspended particles. After a water sample is collected, it might or might not be filtered before the lead concentration is analyzed. If filtered, the pore size of the filter used can influence the measured lead concentration by removing fine particles that contain lead. A standard filter pore size is 0.45 µm (EPA 1996). The lead concentration measured in a sample after passing through a 0.45-µm filter is typically referred to as the dissolved concentration, whereas *total lead* generally refers to lead measured in unfiltered water samples after acid digestion. The two measurements differ if filtration removes particles that contain lead larger than the filter pore diameter. For example, in one study of more than 100 groundwater samples from private domestic water wells in Pennsylvania, total (unfiltered) lead concentrations varied from 0 to 100 ppb. When dissolved (filtered) lead concentrations were compared with total lead in the water samples, the authors determined that dissolved lead concentrations were lower by 6–18 ppb (Swistock et al. 1993).

Lead Partitioning

Given the low concentrations of dissolved lead found in most natural waters, surface sorption (adsorption or ion exchange) of Pb^{2+} onto mineral surfaces or organic matter will likely be the most common mechanism of lead removal from solution to solid phases in surface environments rather than precipitation of new lead species. Precipitation of Pb^{2+} salts, however, occurs in the surface weathering of lead minerals, in evaporative scenarios, and from high-lead surface waters or groundwater near, for example, mining sites or industrial lead sources (see below). Sorption of lead from solution onto mineral surfaces is controlled by pH, solution concentration, and type of mineral surface (Stumm 1992). For example, dissolved lead has a stronger binding affinity to iron hydroxide mineral surfaces than to aluminum hydroxide surfaces, and this results in greater lead adsorption to surfaces of iron hydroxide than to aluminum hydroxide at lower pHs if

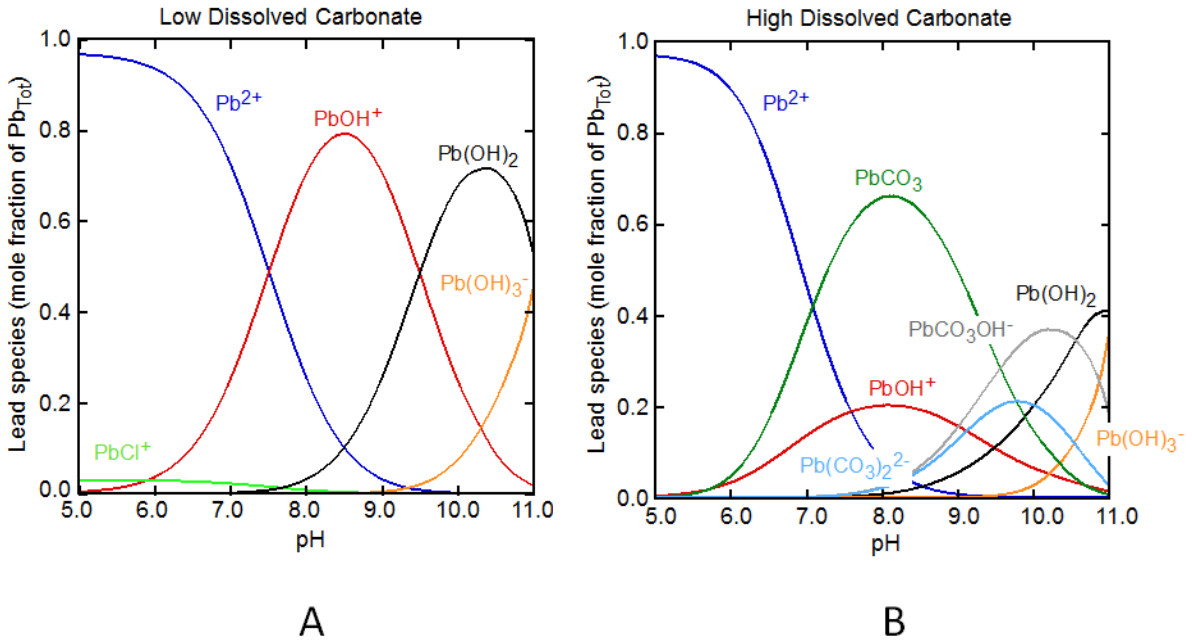

FIGURE 3-1 Dominant lead species in water as a function of pH at (A) low and (B) high dissolved-total-carbonate concentrations. *Low* dissolved carbonate refers to a solution in equilibrium with a partial pressure of CO_2 (g) (P_{CO2}) of about 10^{-5} atm, and *high* dissolved carbonate refers to a solution in equilibrium with a P_{CO2} of about $10^{-3.5}$ atm (about atmospheric CO_2). Calculated with PhreeqC by using equilibrium constants from Powell et al. (2009). Lead species that constitute less than about 1% of the total lead concentration of 2×10^{-6} mol/L are not shown. Copyright National Academy of Sciences. All rights reserved.

the solution concentration and mineral surface area are the same (Figure 3-2) (Serrano et al. 2009). The high affinity of lead for iron and manganese oxides also allows it to outcompete other ions for sorption. Clay minerals can bind Pb^{2+}, particularly at acidic pH, but the bound lead can be displaced by cations, such as Ca^{2+}, when they are present at concentrations similar to that of the Pb^{2+}. Pb^{2+} sorbs to calcite, $CaCO_3$, and other carbonate minerals at alkaline pH (Rouff et al. 2005).

Sorption of Pb^{2+} on mineral surfaces is relatively fast, typically minutes to hours. Depending on the mineral type and aging time, desorption of lead can be mostly reversible (that is, lead is completely removed from the surface and goes back into solution) or only partly reversible (that is, some lead remains bound to the surface) if pH or solution conditions change. Longer reaction or aging time can lead to incorporation of Pb^{2+} into a mineral structure or irreversible binding. For example, a minor amount of Pb^{2+} might be substituted for the divalent cation in carbonate mineral phases, or it might be incorporated into the structure of hydrated iron oxide phases (ferrihydrite or hydrous ferric oxide); this requires dissolution of the solid phase to release lead into solution. The observed slow release of lead from soils in leaching experiments has been attributed to the strong binding of Pb^{2+} to oxoanions in the interlayer of clay minerals and the resulting low rates of desorption from those sites (Serrano et al. 2013).

In soil and sediment weathering, lead-ore minerals, such as galena (PbS), might oxidize, dissolve, or change to form new minerals that might (or might not) be lead-rich solids, such as mixed-element salts or mineral solid solutions. The amount of weathering, rainfall, and leaching in a given environment determines whether lead minerals dissolve completely, change to other solids, or adsorb to other mineral surfaces if dissolved (Hayes et al. 2009). For example, in environments with high rainfall, such ions as lead tend to leach from soils to water, where they are transported as dissolved species, or to adsorb to particles or organic matter in water and migrate as particle-associated species (Schaider et al. 2014; Gutierrez et al. 2016). Organic matter in soils, which is typically more abundant in temperate and tropical environments, tends to retain lead by adsorption and hinder its release to water (Marzouk et al. 2013). In contrast, in arid and semiarid regions where soils undergo intermittent wetting and drying, weathering might result in the formation of carbonate, clay, hydrous oxides, sulfate, or mixed sulfate–hydroxide phases that incorporate lead into their structure or adsorb lead on their surfaces (Dutrizac and Jambor 2000; Jambor et al. 2000).

The pH of water—either surface water or water in the pores of soils and sediments—exerts a strong influence on the dissolution of lead solids derived from original sources (primary phases), the formation of new lead-

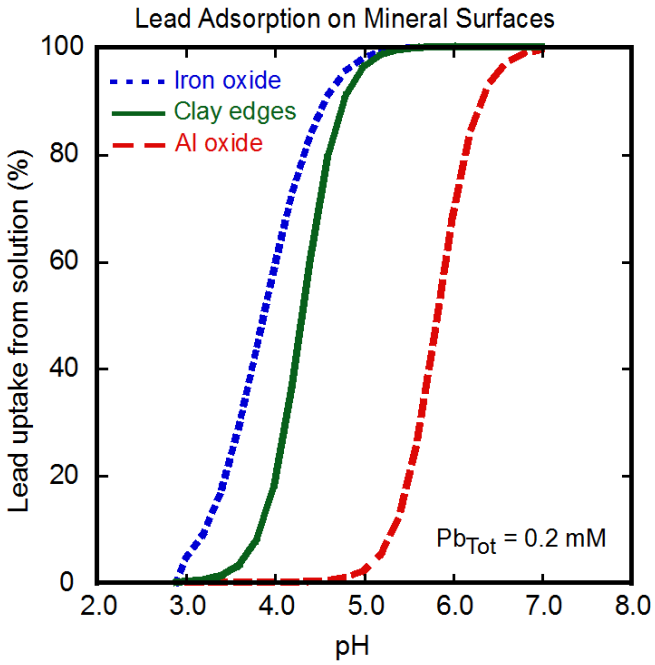

FIGURE 3-2 General examples of lead adsorption (as percent uptake from solution) on mineral surfaces as a function of pH for three soil-mineral types: iron oxide or hydroxide, edge sites of clay minerals, and aluminum oxide or hydroxide. The pH range over which lead sorbs in real systems will vary with solution and mineral-surface-site concentrations. Calculated with PHREEQC by using sorption parameters from Serrano et al. (2009). Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

containing solids by precipitation (secondary phases), and lead adsorption to the surfaces of other soil minerals. The presence of carbonate minerals, such as calcite, in soils and sediments buffers pH near neutral or above (about 7.2–8.2). Given those conditions, lead is often retained by the precipitation of new carbonate minerals or by adsorption. For example, cerussite, $PbCO_3$, was noted as a major secondary weathering phase in sediments that were affected by a historic mining district of Wanlockhead, Scotland (Hillier 2001). Studies of the weathering of lead munitions illustrated that cerussite and hydrocerussite, $Pb_3(CO_3)_2(OH)_2$, were primary products that likely control dissolved lead concentrations in soil-pore water (Jørgensen and Willems 1987; Lin et al. 1995; Cao et al. 2003a; Hardison et al. 2004; Rooney et al. 2007). Similarly, formation of cerussite and mixed lead hydroxide–carbonate phases—including hydrocerussite and plumbonacrite, $Pb_5(CO_3)_3O(OH)_2$—have been reported as products of corrosion of lead pipes (Xie and Giammar 2011; Masters et al. 2016) or products of direct weathering of galena at alkaline pH (Hudson-Edwards et al. 1996; Root et al. 2015). Soils or sediments that have high phosphate concentrations, such as agricultural soils that receive high concentrations of fertilizer, might contain pyromorphite, $Pb_5(PO_4)_3Cl$ (Cao et al. 2003b). As a result of weathering or alteration, secondary lead phases form as crusts or scales on surfaces of galena, lead shot, or lead pipe where lead concentrations are relatively high (Cao et al. 2003a; Pieper et al. 2017). However, at lower concentrations as lead is dispersed, adsorption on clay minerals or amorphous iron oxides or aluminum oxides in soils and sediments is often the primary mechanism for retaining lead and limiting its mobility in water (Hillier 2001; Yang et al. 2006; Rooney et al. 2007).

In areas that have lead-bearing ore minerals and wastes from deposits that contain abundant iron sulfide minerals that produce sulfuric acid during weathering (see Chapter 2), extensive weathering and leaching result in progressively more acidic waters as carbonate is removed and buffer capacity is lost (Hayes et al. 2009; Nordstrom et al. 2015). In acidic conditions in soils and water, the concentrations of iron, aluminum, and sulfate are important controls on lead dispersal or retention in surface weathering or evaporative scenarios. Assemblages of anglesite, $PbSO_4$, and plumbojarosite, $PbFe_6(SO_4)_4(OH)_{12}$, with a wide variety of mixed-metal salts that contain iron, aluminum, and sulfate are common products of lead-rich weathered ore deposits and mine wastes (Dutrizac and Jambor 2000; Jambor et al. 2000). Soils and evaporated sediments that have high dissolved lead and sulfate concentrations, such as those associated with tailings impoundments or mine drainage, might contain anglesite; possibly linarite, $PbCu(SO_4)(OH)_2(s)$, if copper concentrations are high; or lead substituted in many other hydrated-sulfate salts (Jørgensen and Willems 1987; Bigham and Nordstrom 2000; Jambor et al. 2000). The sulfate–hydroxide phases often precipitate and dissolve quickly as conditions change, but reaction rates in different environments will depend on particle size, mineral crystallinity, pH, and solution composition.

Sediment-Associated Lead Dispersal in Rivers

As noted above, lead has a high propensity to be sorbed (attached) to particulate matter under the geochemical conditions observed in most rivers. The concentration of lead associated with particulate matter also tends to be orders of magnitude higher than the concentrations of dissolved lead in surface water or groundwater. Given the concentrations of lead associated with particles and the ability of rivers to move large quantities of sediment, rivers are highly efficient in transporting lead considerable distances downstream from a natural or anthropogenic source. The movement of sediment-associated lead from historical mining and milling operations can be particularly pronounced because waste materials were often stored within impounded river valleys and allowed to enter a river channel unabated.

The downstream transport of sediment-associated lead is a function of the size of the sediment that is being moved and the energy provided by the flow to perform mechanical work. In general, the higher the flow (discharge), the more sediment and sediment-associated lead can be transported through a given stream segment, although the relationship between flow and sediment transport is complicated. Transport of suspended sediment depends on factors—such as the existing soil moisture conditions; rainfall volume, duration, and intensity; and vegetation cover—that influence the movement of sediment from upland areas to the river. As a result, concentrations of suspended sediment and sediment-associated lead vary widely between floods and nonlinearly during a single event, and quantification of suspended sediment and particulate lead transported through a stream segment requires the monitoring of numerous floods over multiple years and an understanding of how concentrations of particulate lead change during a runoff event.[1]

The downstream dispersal of sediment-associated lead (and other trace metals) from a point source generally creates a distinctive systematic downstream decrease in lead concentrations in the sediments in the channel and its associated valley. Figure 3-3 provides an example of the spatial trends commonly encountered for metals downstream of point sources of contamination along the Rio Chilco–Rio Tupiza drainage system of southern Bolivia. Lead, zinc, and antimony concentrations are relatively low at site RC-3 and are comparable with local background values. Concentrations of the metals or metalloids abrupt-

ly increase immediately downstream of the Rio Abaróa, a tributary contaminated by antimony mining and a tailings impoundment failure (Villarroel et al. 2006). The abrupt increase is presumed to result from the influx of contaminated sediment from the mine site. Concentrations of all three elements then decline systematically downstream. However, zinc concentrations abruptly increase again on reaching the confluence of the Rio Tatasi and to a lesser degree the Rio Matsu Cuya. Both drainages contain large-scale mining operations where tailings have entered the channel. Thus, the increased concentrations reflect the additional input of zinc-contaminated tailings into the river.

Longitudinal decreases in lead concentrations, such as those documented downstream of the Rio Abaróa, result from the interaction of multiple processes (Figure 3-4) (Lewin and Macklin 1987; Macklin 1996; Miller and Orbock Miller 2007). Those processes include (1) dilution associated with the dispersal of sediment-associated lead from a relatively small source area over a much longer segment of the river, (2) dilution caused by the mixing of contaminated particles with clean sediment from tributaries and eroded bank deposits, (3) the deposition and storage of lead in the channel bed and other alluvial deposits (a process that removes sediment-associated lead from further transport), and (4) the hydraulic sorting of contaminated particles as a result of the selective erosion, transport, and deposition of larger or denser grains, such as galena. In addition, geographic patterns in lead concentrations can be influenced by the geochemical processes described earlier. Although the downstream dispersal of sediment-associated lead can be systematic, a number of processes complicate geographic patterns in dispersal. The most important are described below.

Lead Partitioning between Particles That Have Different Physical Properties

In most rivers, lead is largely associated with chemically reactive, fine-grained sediments (Horowitz 1991). During their downstream transport, the sediments might be hydraulically separated by particle size and density in localized areas of the riverbed and its floodplain; each area has a distinctive range of particle sizes. Such areas in the river include pools, riffles, point bars, and glides (Figure 3-4a). Within the floodplain or bank, the particles form packages of sediment referred to as vertical accretion deposits, lateral accretion deposits, crevasse-splay deposits, and oxbow lake deposits, and others (Figure

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

3-4a). Such particle partitioning results in the concentration of lead in specific areas of the drainage network that contain fine-grained, lead-enriched particles (Macklin et al. 1999; Macklin et al. 2006; Miller and Orbock Miller 2007).

Along rivers that are affected by the influx of mining and milling debris, lead is associated not only with fine-grained sediment but with coarse-grained sediment (Moore et al. 1989; Miller et al. 1998). The exact distribution depends largely on the milling process used and on how metals were incorporated into the tailings (waste) materials. For example, Pavlowsky et al. (2010) found that high lead concentrations in tailings from the Leadwood and National Piles in Southeast Missouri occurred in the sediment fraction measuring less than 63 μm and in the fraction measuring 4–8 mm. Lead concentrations associated with particles of an intermediate size were relatively low because the milling process was more efficient in recovering lead (and zinc) from these particle sizes. Thus, the geographic distribution of sediment-associated lead is likely to reflect the spatial distribution of particle sizes in the river valley.

In addition to particle size, grain density might affect partitioning of sediment, particularly in mineralized areas. For example, some minerals, such as gold and galena, have a relatively high density. Those dense mineral grains are often concentrated in localized zones in which the denser but smaller metallic grains coexist with larger but less dense minerals, such as quartz, feldspar, and carbonate minerals. The zones of concentration, which are called placer deposits, are created by the repeated processes of erosion and redeposition of particles of a given size range (Slingerland and Smith 1986). Placers tend to form upstream of natural protrusions that are caused by resistant strata where bedrock is present and upstream of manmade structures, such as road crossings and small dams. Placers might also form along rivers where the channel perimeter is composed of sediments. Those types of placers are formed in areas where the repeated erosion and redeposition of sediment concentrates the denser particles, such as at the base of point bars, the head of midchannel bars or islands, and the confluence of tributaries (Guilbert and Park 1986).

Not all differences in the concentration of sediment-associated metals observed between the depositional units of a river can be attributed to particle size and density (Graf et al. 1991; Hudson-Edwards et al. 2001). Areas in the channel that are inundated or flooded more often commonly exhibit higher sediment-associated metal concentrations (Graf et al. 1991). The influence of inundation frequency on metal concentrations is related to two primary factors. First, the more an area of the channel is flooded, the greater the opportunity for sediment-associated lead to be incorporated into the area's channel sediments. Second, the frequency of inundation depends on flood size: topographically higher and less frequently inundated areas are flooded during larger runoff events. In many contaminated rivers, sediment-associated metal concentrations decrease with increasing flow because there is an increased influx of clean sediments to the channel from upland areas of the basin. The clean sediments decrease the concentrations of the metals in the sediments that are incorporated into the less frequently inundated channel areas (Marron 1987).

Localized Downstream Variations in Sediment-Associated Lead Transport and Deposition

Many river systems exhibit abrupt changes in their capacity to transport sediment along the drainage network (Macklin and Lewin 1989; Miller and Villarroel 2011; Miller et al. 2012). For example, segments of the stream characterized by higher gradients and narrower than average valleys tend to transport sediment and sediment-associated lead with little deposition. In essence, flood waters are confined by the narrowness of the valley to a smaller area, which when combined with higher gradients creates more energetic and erosive flows. In contrast, sediment transport is reduced in sedimentation zones that are characterized by wide valleys and shallowness (Mackin and Lewin 1989; Mackin and Dowsett 1989; Mackin 1996; Miller et al. 2009). As a result, systematic downstream trends in the concentration and storage (deposition) of sediment-associated lead might be locally disrupted by changes in river and valley gradient and width. The influence of river or valley gradient and width on geographic patterns of sediment-associated metal concentrations is most pronounced along rivers in mountainous terrain but can also be important along lowland rivers.

Influence of River Transformations on Sediment-Associated Lead Dispersal

Lewin and Macklin (1987) argued that the dispersal of sediment-associated metals differs between rivers in a stable, equilibrium state and those in an unstable, disequilibrium state. The latter are characterized by continuing changes or transformations in channel width, depth, slope, and sinuosity caused by localized erosion or deposition. Transformations in river structure are important because they influence the rate at which sediment-associated metals are transported to downstream areas and are important determinants of the sites along the river where sediment-associated metals are deposited and stored. A relevant example is the influx of large quantities of sediment and tailings into a river from historical mining or milling operations. The increased sediment load often overwhelmed the transport capacity of the river near the site of sediment input and caused deposition on the riverbed and on the adjacent floodplain. Deposition was often substantial and in

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

some cases measured several feet to tens of feet in thickness (Gilbert 1917; James 1989; Knighton 1991). Once the influx of sediment from the mines or mills decreased, the river was able to transport the previously deposited sediment downstream, but some remained in the stream segment and was exposed within the riverbanks, where it could be eroded and re-enter the river. The sediment that was transported downstream often overwhelmed that portion of the river and caused deposition there until sediment loads declined, at which point the riverbed was eroded and the cycle repeated itself further downstream. When viewed in its entirety, the cycle of deposition and erosion formed a kind of sediment wave that migrated downstream from the site of sediment input (Gilbert 1917; Knighton 1991; Nicholas et al. 1995). The downstream passage of the wave typically took decades to complete and strongly influenced the rate at which sediment-associated metals were transported along the river.

The influx of sediment from historical mining and milling operations is not the only type of disturbance that can cause such transformations in river structure and sediment transport rates. In fact, such changes in river function are associated with a wide array of natural disturbances (such as landslides and wildfires) and anthropogenic activities (such as deforestation and land-use change). One of the most widespread and extensively documented disturbances in the United States that led to such transformations in river form was land-use change initiated by European settlement during the late 19th and early 20th centuries (Trimble 1974; Knox 1989; Orbock Miller et al. 1993; Price and Leigh 2006; Leigh 2010). Specifics of the documented changes in the river basins vary between sites; however, they were generally characterized by (1) large-scale devegetation of hillslope and valley bottoms that resulted in an increase in runoff to the drainage network, (2) gullying and accelerated erosion of upland soils that led to an increase in sediment loads into the channel, (3) deposition of sediment on floodplains or riverbeds that produced what are commonly called legacy sediments, and (4) a period of reforestation and improved watershed management practices that resulted in reduced runoff, sediment yield, and, in many cases, channel erosion (Trimble 1974; Knox 1987).

During the above transformations in rivers and river valleys, lead associated with natural soil particles might be incorporated into the sediments that are deposited along the river, particularly the floodplain. After erosion of the riverbed, those sediments (including any lead that they contain) will be exposed in the riverbanks (see Figure 3-5), where they might continue to be eroded and reintroduced to the river (James 1989; Miller et al. 1998; Bain et al. 2012; Niemitz et al. 2013). Such processes might be particularly important along rivers that drain mineralized rocks, such as in Southeast Missouri.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

The erosion and lowering of the river bed also forms an alluvial terrace. Terraces are old floodplains that because of erosion and lowering of the river bed now exist topographically above and adjacent to the river and its floodplain (Figure 3-4). Terraces often contain sediment-associated lead that was deposited by the river but is now spatially removed from the modern channel. Geographic patterns in sediment-associated lead concentrations in terraces are influenced by the timing of lead inputs into the river, terrace height above the modern channel, and the frequency with which the terraces are flooded. During the period of lead influx, lower elevation terraces are likely to have higher concentrations and larger quantities because they are inundated more frequently. After the influx of lead, contaminated sediments on the lower terraces are likely to be buried more rapidly by sediments that have lower lead concentrations. Thus, lead-contaminated soils can be at or closer to the surface on higher terraces than on lower terraces or the floodplain (Brewer and Taylor 1997).

AIR TRANSPORT

Airborne transport has the greatest potential to disperse lead emissions because the air is not confined by geographic barriers. Furthermore, rates of transport of contaminants are often higher for the air pathway than for groundwater and surface-water pathways (Prabhakar et al. 2014). The potential for lead transport via the air pathway can be illustrated with data from Southeast Missouri. Specifically, lead concentrations that were reported as part of monitoring for National Ambient Air Quality Standard (NAAQS) compliance indicate that lead is transported via the air pathway, and the measurements provide some indication of the sources responsible for the airborne lead. Nonattainment occurred in three counties—Iron, Dent, and Reynolds—in the Southeast Missouri Lead Mining District. One site includes the nearby secondary lead smelter (Boss, MO) that reported a 3-month running lead average of 0.17–0.18 μg/m^3 in April–August 2016.[2] Some monitoring sites in the facility fence line reported higher 3-month average values of 0.24–0.33 μg/m^3 from December 2016 through March 2017 (MO DNR 2017). An example of long-term variation in ambient lead concentrations in 2011–2016 is shown in Figure 3-6 and summarizes US Environmental Protection Agency (EPA) data. Although large decreases in total suspended particulate (TSP) lead concentrations in the Herculaneum and Doe Run areas were found after the smelter closed at the end of 2013, 588 samples showed that 24-hr lead concentrations exceeded the NAAQS threshold, 0.15 μg/m^3, in 2014–2016 (EPA 2017).

A fundamental characteristic of suspended particulate matter (PM) that affects transport is its size distribution, often expressed as a function of the particle's aerodynamic diameter.[3] The size distribution affects aerosol physics, chemistry, and transport, and environmental and health effects. This section first describes particle-size distributions and how they affect transport and then fugitive dust suspension and deposition, which are probably the most relevant to lead dispersal from mining-associated sites and other sources. The section concludes with an example of modeling of air transport.

Particle-Size Distribution and Implications for Transport

Airborne PM can range in diameter from a few nanometers to a few hundred micrometers, a span of 5 orders of magnitude, and follows a size distribution like that shown in Figure 3-7. Particles that have an aerodynamic diameter of greater than about 2.5 μm are called the coarse fraction, and particles that have an aerodynamic diameter of less than about 2.5 μm are called the fine fraction, which includes the nucleation, ultrafine, and accumulation fractions. Because mass scales with the cube of the diameter, PM *mass* concentrations are often dominated by the presence of large particles. Conversely, PM *number* concentrations are dominated by the smallest particles. The different size fractions have different sources, removal mechanisms, transport characteristics, atmospheric residence times, and deposition patterns in the environment and the respiratory tract.

Coarse particles (greater than 2.5 μm) are generated by mechanical action, such as crushing, grinding, material handling, wind erosion, or vehicular traffic (Watson et al. 2000). Large particles have high gravitational settling velocities and can deposit onto a surface within a few minutes to a few hours after suspension. For example, chat piles in Southeast Missouri consist of large particles, which are unlikely to become suspended and transported long distances by direct wind action except during extreme weather events, such as tornadoes. Particles that have diameters of a few micrometers, however, can remain suspended for several days and can therefore be transported long distances, even across continents or oceans. Atmospheric turbulence plays an important role in lofting suspended particles from near the ground to higher altitudes, thereby facilitating long-distance transport (Pye 1987).

Fine particles (less than 2.5 μm) are typically generated by condensation of hot vapors and by diffusion and coagulation of gases and other fine particles. Like smaller particles described above, fine particles can be transport-

[2]Nonattainment occurs when air quality is not in compliance with the NAAQS; that is, when the rolling 3-month average exceeds 0.15 μg/m^3.

[3]Aerodynamic diameter (d_a) varies inversely with the square root of the density. It is different from the geometric diameter (d_g); $d_g = d_a/\sqrt{\text{density}}$.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

ed long distances. For example, lead-smelting activities in Southeast Missouri probably emitted lead-containing vapors that nucleated and condensed into fine particles (Moravec et al. 2015) or that condensed onto the surfaces of pre-existing fine particles; these particles were then transported long distances and deposited on the Earth's surface through both dry and wet deposition where they might still be present in soils.

Fugitive Dust Suspension and Mechanisms

Fugitive dust (Chow and Watson 1992; Kinsey and Cowherd 1992; Watson et al. 2000; Amato 2001; Cowherd 2001) consists of small particles that are suspended in the atmosphere after emission from such sources as mining pits, open fields and parking lots, paved and unpaved roads, agricultural fields, construction sites, dry lakes (playas), unenclosed storage piles, and material transfer systems. Visible dust plumes are often noticed over those sources when wind speeds are high or when vehicles are moving. Studies show that, on the average, fugitive dust contributes about 40–60% of PM_{10} and about 5–20% of $PM_{2.5}$ measured in the atmosphere (Watson and Chow 2000). However, fugitive dust contributions are often overestimated when published emission rates are used in dispersion models that simulate contributions to receptor concentrations (Watson et al. 2000) because the meteorologic, physical, and chemical factors on which fugitive dust emission rates are based can vary widely on local, regional, and national scales.[4] Resolving discrepancies between emission estimates and ambient measurements is an important consideration in designing, applying, and evaluating control strategies that are intended to reduce fugitive dust emissions.

As illustrated in Figure 3-8, dust suspension involves a complex three-step process: creep, saltation, and suspension. Creep is the rolling of the largest particles (about 500–1,000 μm) that are not suspended without extreme wind events; as the wind pushes them along, they can roll over and disaggregate other particles. Saltation is the movement of large particles (about 100–500 μm) that bounce a few centimeters above the surface and then fall back down, thereby bombarding the surface; upon impact, they dislodge smaller particles (less than 100 μm) from the surface, which can be entrained in the prevailing airflow. Creep, saltation, and suspension are inherently chaotic processes that are difficult to model (Shao 2008; Kok et al. 2012; Valance et al. 2015). Instead, semi-empirical models are used to estimate dust production from soils and stockpiles, such as chat piles and mine-tailings impoundments.

The suspension of fugitive dust particles depends on particle sizes, surface loadings, surface conditions, wind speeds, atmospheric and surface moisture, and the existence of dust-generating activities, such as vehicular traffic. Windblown dust occurs when the wind exceeds a threshold velocity. The minimum threshold wind velocity is often found to be about 5–10 m/s when extrapolated to 10 m above the surface (the standard height for reporting wind speed). However, the threshold can vary widely because of such factors as surface roughness, moisture content, vegetative cover, and particle size. Portable wind tunnels are increasingly used in the field to measure dust emissions and threshold wind velocities directly

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

(Etyemezian et al. 2007). Figure 3-9 illustrates how the PM_{10} emissions can vary as a function of wind speed and surface conditions. Such emission measurements can be used in computational fluid-dynamics models to simulate atmospheric dispersion of dust (Stovern et al. 2014). Those models, for example, can be coupled to lead-isotope data to improve attribution of lead to various sources (Stovern et al. 2016).

Mechanical suspension processes are dominated by moving vehicles, wherein the contact of a tire with the surface of a roadway grinds the dust to smaller sizes and injects it from the road surface into the atmosphere. Vehicle wakes that create turbulence are also sources of dust suspension, although they can also be classified as wind-induced. Other mechanical suspension methods involve transfer of bulk materials through uncovered conveyors, bulldozers, shovels, and open trucks.

Modeling Air Transport: An Example from Southeast Missouri

An example from Southeast Missouri illustrates the potential for air transport of lead-containing particles from chat piles and tailings. Abbott (1999) modeled the erosion and transport of airborne PM from chat piles and tailings impoundments at Bonne Terre, Desloge, Leadwood, National, Elvins, and Federal in Southeast Missouri. The model was evaluated using data from air-quality monitors—presumably TSP monitors, but that is not stated—at four locations and downwind soil sampling. As expected, predicted transport from coarse chat piles (0.5–1.0 km) was less than transport from the fine tailings (3–5 km). The highest deposition rates were predicted for areas east and southeast of the sources, which would be consistent with the prevailing wind direction. The maximum annual average calculated lead deposition rate 1 km downwind from tailings impoundments was about 1–30 $\mu g/m^2$-hr. Although model predictions and atmospheric observations varied from site to site, the predicted airborne lead at the Desloge site was reasonably close to observations with respect to both annual average (0.1 $\mu g/m^3$) and maximum 24-h average (1 $\mu g/m^3$) concentrations. Soil sampling showed the expected rapid decrease in lead concentration with distance that reached more typical concentrations at about 2 km downwind from the Bonne Terre sources, which were mainly tailings and a small chat pile.

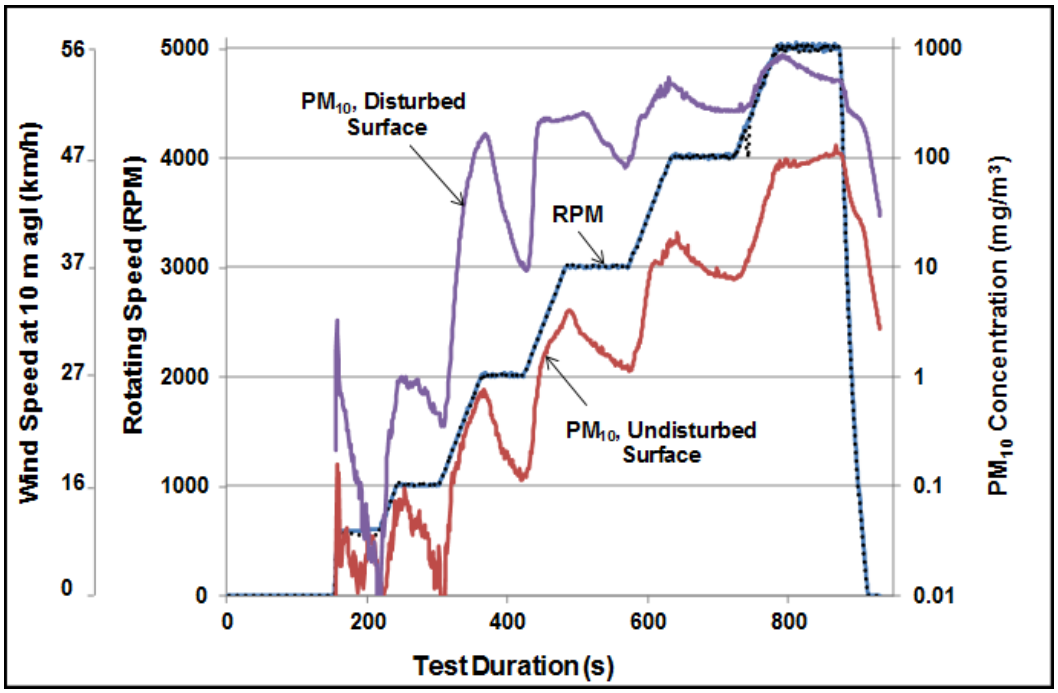

FIGURE 3-9 Comparison of PM_{10} suspended at different wind speeds from mechanically disturbed surfaces (such as a broken surface crust) and undisturbed surfaces of a coke storage pile; data collected using a portable wind tunnel (Etyemezian et al. 2007). Emissions increase with wind speed for both disturbed and undisturbed surfaces, but the emissions are more than an order of magnitude lower for the undisturbed surface. Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

A decade later, the Missouri Department of Natural Resources reported that airborne lead concentrations monitored near a chat pile during earth-moving operations could rise to 0.3 $\mu g/m^3$ (24-hr average) despite the coarse particle diameter of chat (MO DNR 2009). High lead observations from TSP monitors were also reported at St. Joe State Park (up to 0.9 $\mu g/m^3$) and from personal monitors (up to 6 $\mu g/m^3$, time-weighted average) worn by motorcycle riders in the vicinity of the disturbed surface of the chat pile (MO DNR 2009). Such observations near chat sources show that in spite of the very large particle diameter, chat can be an important lead source where anthropogenic mechanical disturbance occurs. That observation is important because chat was spread on roads, where the coarse particles can be ground up by traffic, and then suspended by the passage of vehicles or wind erosion. The grinding and resuspension of chat could be an important lead source; it has been reported that some road dust in Southeast Missouri contains higher lead concentrations than are measured elsewhere in the region (Witt et al. 2013, 2014, 2016).

The Abbott (1999) study used meteorologic observations from the St. Louis airport 80–100 km away; wind was predominantly toward the east and southeast, but these wind directions probably do not reflect local conditions, where the topography might channel the flow in a more northerly or southerly direction. The study demonstrates the importance of making local meteorologic observations for source dispersion modeling, as discussed further in Chapter 4.

INTENTIONAL TRANSPORT

Intentional transport includes all the human activities that move materials within and off a site. For example, intentional transport at mining sites in the Southeast Missouri Lead Mining District would include the mechanical, truck, or rail transport of lead ores, lead concentrates, or lead-containing mine wastes (waste rock, tailings, and slags) for further processing, disposal, or beneficial use, such as use of chat as soil amendments on agricultural fields and use of tailings as railroad-bed material. McHenry (2006) compiled a history of the mining companies and chat dumps of the Missouri Lead Belt in St. Francois County and reported considerable anecdotal information about transport of mine wastes, particularly chat, for beneficial uses. Before 1922, chat was offered "free for the asking and many thousands of tons were hauled away by local citizens, city, county and state government, and other industries in the area which had uses for it." As noted in Chapter 2, one primary use was as an agricultural lime; in 1922, chat began to be sold to limestone dealers for use as a soil amendment. Chat sales continued until 1972, when one chat pile that originally contained 3,522,000 tons was entirely gone (Karsch 1973). Other uses noted by McHenry (2006) were as a component of blacktop, concrete, fill material in building construction and road grades, sandbox sand, and grit for deicing streets and sidewalks.

The intentional transport of mine wastes for beneficial use is of concern as a potential vector for public-health and environmental problems. The Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) remedial investigations (RIs) for mining sites and other industrial sites that have generated large quantities of potentially valuable byproducts do not systematically consider intentional transport mechanisms. Because intentional transport is a business activity, the process of identifying and quantifying intentional transport processes involves locating and auditing business records, such as transport manifests, invoices and receipts, inventory records, and informal communications (oral and written). The systematic consideration of intentional transport mechanisms then falls under the purview of accountants, economists, and historians, who are rarely engaged in such activity for CERCLA RIs, perhaps because of an absence of EPA guidance that articulates the need for and role of qualified practitioners in these professions in systematically considering intentional transport mechanisms.[5]

One approach for encouraging systematic consideration of intentional transport would be to eliminate the use of the term *migration* to describe the transport processes to be considered because its use implies that contaminant transport is governed only by air and water dispersion processes. Furthermore, a recommendation to consider intentional transport mechanisms could be added to guidance documents.

Investigative Strategies for Lead-Source Attribution

During the last several decades, a wide array of analytic techniques have been used, with varied degrees of success, to determine the relative contributions of lead from natural and anthropogenic sources in soils, sediments, water, and air. The US Environmental Protection Agency has used several methods in its investigations, including using elemental concentrations and ratios, isotopic analysis, and other soil-metal characterizations (Burgess 2016). Most techniques rely on a fingerprinting approach that attempts to identify unique physical or chemical characteristics that can distinguish lead or lead-associated materials between suspected sources (Box 4-1). Once the sources have been assessed, the distinguishing source characteristics can be compared with those of samples of soil, sediment, water, and air to assess the origin of the lead. Given the variety of analytic methods that are available, integration of the most appropriate techniques is challenging (Gallego et al. 2016).

In this chapter, the committee provides a series of investigative strategies that are stratified by media type. The strategies are intended to provide a logical framework for determining the source of lead while minimizing the time, effort, and financial resources required to do so. They are not intended to replace procedures associated with the remedial investigation and feasibility study but are meant to serve as a general guide to lead-source attribution. Given the highly variable nature of lead contamination near and adjacent to Superfund sites, not all the methods that are listed in the strategies will be applicable to all sites. In some cases, additional methods not cited in the strategies might be useful. Furthermore, the strategies might require modification to fit the specific characteristics of an individual site or operable unit.

The suggested strategies are based on a multiple-lines-of-evidence approach, in which data are systematically collected, analyzed, and interpreted until there is sufficient confidence that a method (or combination of methods) has resulted in a sound understanding of the sources of lead. The methods inherent in the strategies represent tested techniques that generate results that are widely accepted by the scientific community (unless otherwise stated). Preference was also given to techniques that generate quantifiable degrees of uncertainty.

SOIL

The committee's investigative strategy for soil is shown in Figure 4-1 and provides a guiding framework for deducing lead sources in soil. In this section, the committee focuses on soils derived from underlying rock strata as opposed to materials that are transported by river, gravity, or wind. The section that follows focuses on river sediments and sites within active floodplains where alluvial deposition is occurring regularly or has occurred over the duration in question for lead deposition.

The committee provides a possible sequence of analyses for soil based on typical successful outcomes, but the sequence might be adjusted on the basis of site-specific conditions, availability of instrumentation, and resource (cost and time) considerations. Before investigation of the source of lead, total soil concentrations need to be measured; sites (or samples) exceeding a regulatory threshold can then be examined for the lead source.

Site Characterization and History

Before a detailed chemical or mineralogic analysis is conducted, a basic site characterization and history should be developed that leads to a site conceptual model that can guide investigations toward likely lead sources; potential contributors of lead noted in Chapter 2 should be specifically identified. The landform of the soil or yard should be noted in terms of its current geology and likely geologic past. The US Department of Agriculture soil survey should be consulted for information on soils and landforms of the area. A history of land use at the site should also be constructed from public records and on-site observations to address appropriate questions, such as, Are there or have there been buildings constructed before the 1980s on the site that could have contributed lead-based paint to the

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

BOX 4-1 Lead Attribution Using Physical and Geochemical Fingerprinting Techniques

The attribution of lead in soils, sediments, water, and air commonly relies on the application of physical and geochemical "fingerprinting" methods. Although the approach varies widely with the media under investigation, the general assumption is that the physical or chemical composition of a sample is a function of the characteristics or composition of the lead sources and the relative amount of each source that contributes to it. This situation is referred to as an inverse (or unmixing) problem (Weltje 2012). Solution of the problem generally involves a four-step process (Zhang et al. 2012): (1) delineation and characterization of the lead sources, (2) identification of the physical or chemical properties (the fingerprint) that can distinguish the identified lead sources, (3) collection and characterization of samples from the media or site under consideration, and (4) determination of the relative contribution of lead by each source on the basis of some form of mathematical model. The latter step also includes an assessment of uncertainty associated with the modeling results.

Ideally, the fingerprint represents a unique property or set of properties that separate one source from all other sources. However, unlike a human fingerprint, the fingerprint of a lead source is, in many cases, imperfect. Because of inhomogeneity in the physical and chemical composition of the lead sources, the value or characteristics of the fingerprinting properties might be statistically distinct but overlap. The key, then, is to identify physical or chemical properties that most effectively distinguish between lead sources. A large number of physical and chemical measures have been used in fingerprinting analysis (see, for example, D'Haen et al. 2012 or Guzmán et al. 2013). Some use lead-related characteristics to fingerprint lead sources directly (such as lead concentrations, lead-isotope ratios, and ratios of lead concentrations to other elemental concentrations). Other fingerprinting analyses rely on properties of the media with which the lead is associated. For example, the fingerprinting of sediment-associated lead in rivers often relies on the concentration of multiple elements in the sediment or magnetic properties of the sediment in which lead is found.

Once a fingerprint to distinguish the sources has been defined, mathematical models of various types can be used to determine the relative contributions of lead from each source. During the last 2 decades, a wide array of analytic and statistical methods of increasing complexity have been developed to improve source attribution and to characterize the uncertainty inherent in the results.

soil? Are there obvious atmospheric point sources, such as a smelter or mine, in the near vicinity? Has mine-waste material with high lead concentrations been deposited on the site as backfill or roadway material? Is there evidence of storage or disposal of lead-acid batteries on the site? Once basic questions have been considered, a detailed soil sampling protocol can be developed for the specific site. As part of the development of a conceptual model, a handheld x-ray fluorescence (XRF) analyzer can be used to survey the surface-soil lead concentrations and guide soil sampling for additional analyses.

The field characterization should then proceed to determine whether the soil has been disturbed by human activity, whether the site is in an active floodplain and is a location where recent alluvial sediments have been deposited or eroded, and whether the soil was developed in situ (the nature of the underlying parent rock material). Disturbance by human activities is likely to alter spatial and depth trends in lead concentrations and might have led to the direct incorporation of anthropogenic lead into the soil. In Southeast Missouri, for example, coarse-grained tailings (chat) that contain lead were used extensively as fill and thus have been observed to be incorporated into disturbed soils in the region. Similarly, dispersal and source alteration from, for example, weathering processes described in Chapter 3 should be considered.

The distinction between soils composed of alluvial (riverine) and nonalluvial parent materials is an important consideration in site assessment because of differences in vertical patterns of lead concentration. Anthropogenic lead in soils of floodplains that were recently active (in the last century) often extends to depths measured in meters; anthropogenic lead in soils where the parent material was not deposited by the recent action of rivers is generally confined to within a few tens of centimeters of the ground surface. Thus, the topographic setting and type of soil parent material dictate the nature of the sampling program required to assess lead attribution. The following discussion of depth sampling and spatial analysis is for soil developed in place without active deposition where diagnostic vertical distributions tend to be retained as opposed to soils that are subject to recent alluvial deposits (active floodplains).

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

Spatial and Depth Sampling and Analysis

The spatial distribution of lead in a location is often a clue to its source. Anthropogenic sources of lead in soils are commonly deciphered by using two types of spatial analysis: an assessment of geographic patterns in lead concentration in the topsoil and a spatial analysis of lead as a function of depth below the ground surface. Geographic patterns in lead and other trace-metal concentrations are usually determined by collecting and analyzing composite samples of the topsoil with a gridded sampling scheme (Stafilov et al. 2010) or along transects that radiate from a suspected source, often corresponding to wind direction (Ettler 2016). Alternatively, the data might correspond to the distribution of residences that are sampled in urban areas. With the advent of hand-held XRF units, assessing spatial variation in lead can be easy and rapid and provide key information on lead sources. For example, high concentrations along the dripline of a home suggest that the source is paint or lead particles that have washed off the roof. Materials used for roads or driveways might contribute to high lead concentrations in nearby soils where concentrations decline with distance. Lead distribution, however, might also have nonunique source signals whereby natural, alluvial, or aerially deposited material might all show similar patterns that require further analysis.

Depth sampling and analysis might help to identify the lead concentration in soil parent material and layers that have been enriched by human activities and thus aid in source attribution. Here, the parent material for a soil is simply the rock (or unconsolidated rock material) that now underlies the soil. Soils develop through interaction of parent material with water, gas, living organisms, and organic matter in a given climate over an extended period. Parent material is generally determined through geologic inspection and chemical, mineralogic, and particle-size analysis of samples collected from the bottom of the soil profile and adjacent to the underlying bedrock. To confirm parent composition, multiple elements can be analyzed, and the measured composition compared with the expected weathering behavior of the underlying bedrock derived from modeling (Brantley and Lebedeva 2011). It is gener-

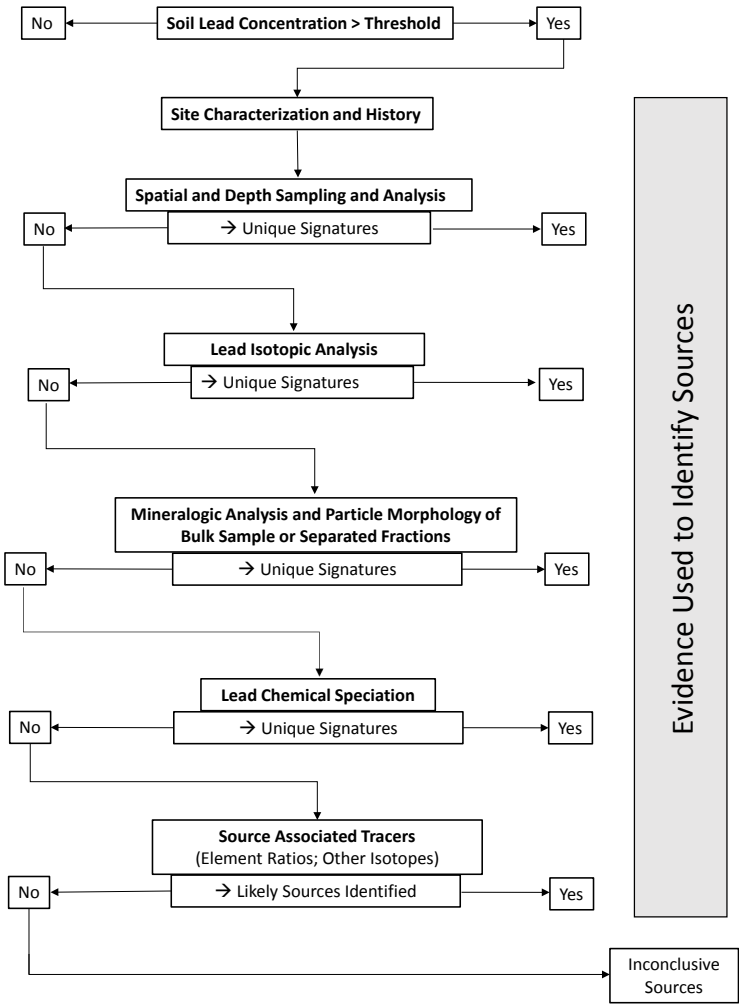

FIGURE 4-1 Example of an investigative strategy for attributing sources of lead in soil. The optimal sequence will depend on site-specific conditions, availability of analytic techniques, and cost and time considerations.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

ally helpful to collect multiple samples of parent material if possible to estimate compositional variability, including sampling of local outcrops or drilling material.

Once parent material is identified, the source of lead in the soil can be investigated. Lead that is present in uncontaminated soils derives from the parent material or from natural inputs of dust or sediment. In contaminated soils, lead derives from those sources and from anthropogenic inputs. By sampling and analyzing the depth distribution of lead and, for example, the isotopic signatures, specific minerals, or elemental ratios in the soil, one might be able to determine a scenario that most likely explains the source of the lead. If the physical or chemical characteristics of the lead in the soil are identical with those in the parent material *and* the depth distribution is consistent with this natural source of the lead, the simplest explanation is that all the lead in the soil is derived from the parent material. If the chemical or physical characteristics of the soil lead instead differ from those of the lead in the parent material and its weathering products, the lead has probably been added to the soil. The analytic methods described below help to define the chemical and physical characteristics of the lead to distinguish its source.

In areas of potential ore deposits, separating natural from anthropogenic lead can be complicated. However, for most cases of soils outside a recently active floodplain, anthropogenic lead will generally be concentrated at or near the soil surface and decrease downward to concentrations similar to those of the parent material. In some cases, if topsoil has been placed over mine wastes or chat, vertical distributions might document a layer that has a high lead concentration between layers that have low lead concentrations. Depth sampling of soil profiles can investigate such diagnostic distributions. Such sampling tends to be conducted at uniform increments or to be stratified according to naturally defined soil horizons.

Most commonly, the magnitude of anthropogenic lead is assessed by comparing concentrations in the surface materials with those in deeper horizons, including parent material. The analyses can be complicated by the downward migration of lead, which can occur by leaching (Miller and Friedland 1994; Prapaipong et al. 2008); the translocation of colloids and clay-sized particles (Citeau et al. 2003); biologic activity caused, for example, by earthworms, gophers, ground squirrels, and plant uprooting; and human activities, including gardening and plowing. The depth and rate of downward migration depend not only on the mechanism and timing of mixing but on the chemical form or speciation of lead in the soil; soil characteristics, such as pH, type and amount of organic matter, and clay content and mineralogy; climate conditions, such as rainfall and temperature; and the nature of the particles with which lead is associated (as discussed in Chapter 3).

Interpretation of lead concentrations as a function of depth in soils can also be complicated because even if lead is not added to or lost from a soil, its concentration can increase upward in a soil if high concentrations of other elements have been dissolved and transported out of the soil by natural processes over geologic time. In other words, lead that is not removed from a soil can become more concentrated near the surface when more soluble materials have been removed. To account for weathering, soil scientists generally normalize concentrations of the element of interest, such as lead, to that of another element that is not present in soluble minerals, such as titanium and zirconium. One such normalization, which has been used extensively in the recent literature, is the mass transfer coefficient[1] (Brimhall and Dietrich 1987; Anderson et al. 2002; Brantley and Lebedeva 2011). The mass transfer coefficient of lead is calculated by dividing two ratios. The first is the ratio of the lead concentration in a bulk soil sample to the concentration of an element, such as titanium or zirconium, that is present in the soil as an insoluble mineral. The second is the ratio of those same two elements in the parent material. When the mass transfer coefficient is analyzed as a function of depth, it can reveal patterns of addition or depletion in the soil that can be interpreted in terms of the lead source (Brantley and Lebedeva 2011). Observed depth distributions can be modeled in terms of processes, such as addition, depletion, or biologic cycling of elements into upper soil layers. Using those approaches, several investigators have modeled the addition of lead to soils from atmospheric deposition (Johnson et al. 1995; Drivas et al. 2011), and depth distributions coupled with isotopic signatures of various potential lead sources have been used to determine sources and migration of lead in soils (Prapaipong et al. 2008).

Lead Isotopic Analysis

Measurement of lead isotopic composition can potentially identify a lead source rapidly if the isotopic signature is unique. The effectiveness of isotopic composition as a fingerprinting tool is related to several factors: stable isotopes of lead can be measured with a high degree of precision and accuracy, lead is unreactive and immobile over a wide range of environmental (geochemical) conditions, and fractionation of lead isotopes by physical, chemical, and biologic processes is minimal in contrast with that of stable isotopes of light elements, such as sulfur, carbon, and oxygen (Keinonen 1992; Komárek et al. 2008; Balcaen et al. 2010; Bird 2011; Miller et al. 2012). Thus, isotopic composition of lead of natural and anthropogenic sources (including ore deposits) does not change appreciably as it is dispersed through the environment. In

[1]The use of the term *mass transfer coefficient* by the authors is different from its use in engineering where it is used widely to characterize the transfer rate of mass between phases.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

most cases, the variation in a soil will be small relative to the differences between the soil and external inputs; thus, observed differences in the isotopic composition of the soil in question can be attributed to its mixing with lead from other sources (Cheng and Hu 2010). Finally, lead isotopic composition of ore deposits on a global scale is highly variable (Bird 2011; Miller et al. 2015), and lead derived from ore deposits tend to differ from lead typically found in non-ore rocks and soils (Hopper et al. 1991). See Chapter 5 for a detailed case study.

Studies conducted over the last several decades demonstrate that lead isotopes are often effective in determining lead sources in soils if the isotopic values of the source materials are unique (Rabinowitz and Wetherill 1972; Gulson et al. 1981; Steinmann and Stille 1997; Steinnes et al. 2005; Clark et al. 2006; Mihaljevic et al. 2006; Prapaipong et al. 2008; MacKinnon et al. 2011; Ma et al. 2014). In many cases, analyzing the depth distribution and isotopic signatures of lead in the soil allows source determination. If the isotopic character of the lead in the soil is identical with that of the parent rock, the simplest explanation is that all the lead in the soil results from the parent rock material. If, however, the isotopic character of the lead differs from that of the parent material, the lead has probably been added to the soil. As an illustrative example, Ma et al. (2014) completed an investigation in Pennsylvania where lead was enriched in soil relative to the parent bedrock. The isotopic signature of the lead varied significantly and consistently upward from the bedrock to the land surface (Figure 4-2). Using the lead isotopic signature, concentration–depth profiles, knowledge of the history of anthropogenic practices in the area, and models, the researchers attributed the added lead to atmospheric deposition between the 1850s and 1920s, when lead was emitted to the atmosphere from coal-burning and ore-smelting in the area (Ma et al. 2014).

Similarly, Steinnes et al. (2005) examined lead concentrations and sources throughout Norway. Their findings illustrate a similar $^{206}Pb/^{207}Pb$ ratio for C-horizons (unconsolidated parent rock material) throughout the country and are indicative of the undisturbed soil baseline lead signature. Using known $^{206}Pb/^{207}Pb$ ratios in atmospheric deposition, they were able to determine the fraction of the lead attributed to atmospheric inputs for lead-enriched surface soils. Gulson et al. (1981) provide another illustrative example. They examined lead sources

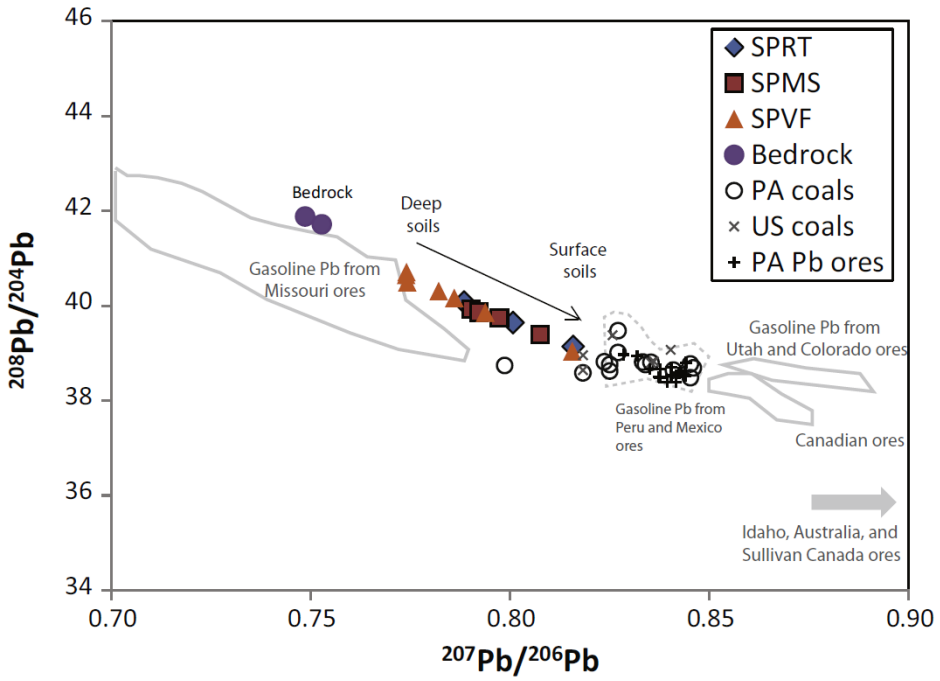

FIGURE 4-2 Isotopic signatures of soil samples from the pristine Shale Hills site in central Pennsylvania compared with various sources of lead. The gray circled areas represent lead-isotope ratios for leaded gasoline *if* the lead were derived from the ores indicated. Solid-colored symbols represent soil or bedrock samples, open symbols represent samples of coal from Pennsylvania, and crosses represent lead ore mined in nearby parts of Pennsylvania. Dashed gray lines indicate the isotopic values of Peruvian and Mexican lead ores that were generally not used in the Great Lakes region (Graney et al. 1995). Soil lead is attributed to a mixture of bedrock and atmospherically deposited lead from local coal-burning and iron or lead ore-smelting; deeper soils contain more bedrock-derived lead, and topsoils contain more coal- or ore-derived lead. Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

in soils near Adelaide, South Australia, by comparing concentrations and isotopic signatures between surface (upper 10 cm) and subsoil (30-40 cm) collected along a path that included urban and rural land use. Subsoil isotopic values were similar throughout the traversed sampling path and were consistent with parent rock; lead in the subsoil was therefore attributed almost entirely to that derived from the parent rock. In contrast, lead from parent rock made up a minor fraction of the total lead in surface soils. Using the isotopic signatures along the transect with the depth comparison, the authors were able to eliminate pesticides, power stations, and smelters as major sources of soil lead; instead, they attributed the lead to gasoline.

Rabinowitz and Wetherill (1972) used isotopic signatures, lead concentrations, and general mineralogic observations to assess sources of soil lead in shallow soil samples (0–2.5 cm and 12.5 cm) in Southeast Missouri and Benicia, California; their work illustrates the benefits and limitations of isotopic analysis for source attribution. In the majority of sites examined from St. Louis to rural areas away from any known ore bodies and sites near ore-processing or gasoline-refining, lead enrichment in surface soil layers could be attributed to specific sources on the basis of comparison with deeper soil layers and measured isotopic values of potential sources. However, a slight enrichment of 25-ppm lead in a surface soil layer near the ore-crushing and beneficiation plant in Indian Creek Mill, Missouri, provided an equivocal isotopic signature. In that case, mineralogy, particle-size distribution, and lead isotopic signature were not sufficient to resolve the source of high lead concentrations in the surface soil. In the other 11 sites examined in Southeast Missouri and Benicia, California, the combination of lead isotopic signature, concentration profiles, and mineralogic analysis allowed source attribution of lead enrichment in surface soil layers.

Using spatially resolved depth variation in lead concentration and lead isotopic signatures, Prapaipong et al. (2008) determined lead sources for soils potentially affected by smelting in Southeast Missouri. Lead isotopes of the smelting ore, which originated from the Viburnum Trend, were distinct from those of the parent materials of soils developed on Bonneterre dolomite or St. Francois rhyolite, and they also differed from the isotopic signature of lead derived from burning of leaded gasoline. The unique signature of each potential lead source allowed apportionment across the study area and with sampling depth. Lead concentrations attributed to smelting decreased with depth to a consistent value (typically 10–30 ppm) and decreased with distance from the smelter. However, within 2 km of the smelter, up to 90% of the lead was derived from smelting operations to depths of 25 cm. Over 4 km away from the smelter, smelter emissions accounted for 10–50% of the soil lead in the upper 15–25 cm. Isotopic analysis revealed that aerially deposited lead (from smelting and automotive exhaust) was present even at depths where concentrations were consistent with natural background. That finding suggests that the naturally occurring lead was displaced from the soil and that a maximum retention capacity was reached; any new lead that entered the soil would therefore either move through the soil or displace lead already present in the soil. To establish temporal trends in soil lead inputs, Prapaipong et al. (2008) examined lead concentrations and isotopic signatures of White Oak tree cores by using tree rings to provide concentration–time profiles. Lead concentration rose sharply 7 years after onset of smelting operations, increased within the tree rings over the following 25 years, and increased by a factor of 10 in trees within 1 km of the smelter. Isotopic analysis substantiated that the rise in lead concentrations was from the uptake of smelter-derived lead. The combined use of tree cores to determine temporal trends with spatial and depth profiles of soils to determine lead concentrations and isotopic signatures provides a powerful means of identifying lead sources.

Thus, if the lead isotopic compositions of the potential sources are unique and the lead isotopic values in the soil of concern fall within the range of the source materials, the contribution of each source to lead contamination can be determined. Given the robust nature of the technique, it might obviate additional analyses for source attribution, and this would greatly reduce the time, effort, and costs involved in determining lead sources. If the lead isotopic compositions of the source materials are similar (that is, they overlap), the method cannot unequivocally assess lead sources, and additional techniques are required.

Mineralogic Analysis and Particle Morphology

Mineralogic analysis of soils, such as optical microscopic identification of sand particles and x-ray diffraction (XRD) analysis of silts and clays, might provide signatures that allow source attribution. Minerals unique to specific sources can help with source attribution. The presence of galena, PbS, and other heavy minerals, for example, might be a clear signature of lead source (Ettler et al. 2005; Cabala and Teper 2007), whereas hydrocerussite, $Pb_3(CO_3)_2(OH)_2(s)$, might precipitate as a soil mineral after weathering of the original lead mineral. As lead disperses in the environment, soil concentrations tend to decrease as distance from the source increases, and lead is more likely to be adsorbed to other soil minerals or to be present as a minor substituent in secondary phases in soils and sediments. As a result, source attribution through mineralogic analyses, although often effective, can be inconclusive in other cases.

XRD has been used extensively for clay mineral identification (see Whittig and Allardice 1986) and to elucidate soil and sediment sources (Eberl 2004; Benedetti et al. 2006). It is often used in conjunction with particle-size

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

or density separation to identify minerals specific to a lead source (Olson and Skogerboe 1975). The mineralogy and particle structure determined with optical microscopy and scanning electron microscopy (SEM) of sand particles has been used extensively on alluvial and dust deposits to track sediment source (Arribas et al. 2000; Abu-Zeid et al. 2001; Cardona et al. 2005; Benedetti et al. 2006) and might serve to attribute lead sources in soil.

SEM coupled with elemental analysis—conducted with energy dispersive x-ray spectroscopy (EDS) or wave-length dispersive x-ray spectroscopy—is an additional means of obtaining chemical information and information on particle structure and texture. A description of the attributes and limitations of SEM and elemental analysis for identifying particle sources is provided in Pye (2004). Specific elemental ratios and morphologic characteristics of particles can be used to infer mineral identity, and combining mineralogy, particle size, and elemental composition has proved successful in source attribution (de Boer and Crosby 1995; Sterling et al. 1998). For example, Linton et al (1980) used specific particle structure and chemical composition to distinguish lead sources between automotive exhaust and paint chips, and Sobanska et al. (1999) used spherical particle structure and elemental composition to identify lead originating from smelters. Demonstrative features, such as spherical structure associated with smelters, can provide definitive source identification, and more subtle etching of sand grains might provide important clues to particle source (Abu-Zeid et al. 2001; Cardona et al. 2005). Figure 4-3 illustrates the use of SEM and EDS to distinguish between spherical lead-containing particles that are indicative of high-temperature processing, such as smelting, and particles that are more characteristic of airborne dust originating from vehicle activity or wind. Transmission electron microscopy (TEM) coupled with EDS and electron diffraction might also be useful for source identification. Mineralogy and particle-surface morphology can be deduced for isolated particles with TEM, which might be particularly useful for small, well-crystallized particles that have a propensity for deposition via wind-borne transport (Buseck and Posfai 1999).

Lead concentrations also tend to depend on particle size in material deposited as dust, with larger particles deposited closer to the source (NEPC 1998). Thus, particle-size analyses that include dividing particles into fine and coarse fractions can help to determine source. Size separation is typically conducted with wire-mesh sieves for particles larger than about 0.05 mm; finer particles are measured by sediment rate separation, suspension density (hydrometer), or laser light scattering. An example of particle-size variation is illustrated by Taylor et al. (2010), who found that lead concentrations within 2 km of mining and smelting activities in Mount Isa, Queensland, Australia, were higher above more distant soils and depended on particle size. High lead concentrations associated within finer particles (<180 μm) extended further from the site. Such geographic concentration data are often combined with dispersion models that predict the downwind deposition and surface concentrations of atmospheric lead from known sources (see, for example, Small et al. 1995).

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

Heavy minerals—such as pyrite, galena, cerussite, anglesite, and sphalerite—can be separated from soils by using fluids of different density. Such fractionated samples (separates) can often be used to associate soil grains with sources of lead contamination. Heavy minerals are particularly effective in tracing airborne lead and other metals derived from smelting and mining operations (see review by Ettler et al. 2016). Heavy mineral assemblages are often examined in combination with particle structure for attribution purposes. For example, the combination of ilmenite, $FeTiO_3$, and particle structure allowed successful determination of particle origin (Basu and Molinaroli 1991), and heavy minerals with quartz stress fractures provided evidence on wind-transported particles (Abu-Zeid et al. 2001).

If heavy minerals are isolated with density separation methods that rely on high-viscosity fluids, the assemblages can be characterized by using mineralogic tools noted above, such as XRD (Burt et al. 2003; Ettler et al. 2005) and SEM–EDS (Cabala and Teper 2007). Density separation has been used extensively for the analysis of minerals in both consolidated and unconsolidated rocks (see, for example, Morton 1985), but it has not been applied much to source attribution of anthropogenic lead in soils. Nevertheless, the method holds promise in that it allows additional mineralogic, geochemical, or isotopic analysis (described above) to be performed directly on heavy minerals.

The attribution of airborne lead and other metals to mining and smelting operations by using heavy minerals has generally been based on spatial variations in the quantity with which they are found in soils relative to the source and the area's predominant wind directions. Calaba and Teper (2007), for example, found that the proportion of heavy minerals, particularly iron sulfides associated with ore minerals, reached concentrations as high as 6–8% within several kilometers of ore-processing sites in southern Poland. Similarly, Ettler et al. (2005) found that anglesite occurred commonly in the dust and fly ash of lead-smelting operations in the Příbram district of the Czech Republic. Thus, they were able to argue that their presence in local soils was a clear indicator of airborne contamination from the nearby lead smelters.

Lead Chemical Speciation

Lead speciation can provide additional means for source attribution, but chemical speciation of lead in soils can be challenging because lead can be dispersed or poorly crystallized or be associated with small particles, all of which makes it difficult to conduct XRD or SEM analyses. Furthermore, weathering, alteration, and dissolution of primary lead compounds can change lead speciation and often result in adsorption of lead on mineral or organic-matter surfaces or its substitution as a minor element in newly precipitated phases. To overcome those challenges, selective extractions have been used commonly to assess the chemical speciation of lead.[2] Most series of selective extractions are based on a method developed by Tessier et al. (1979); various methods are reviewed and summarized by Ure et al. (1993). One potential problem is that although the extracting medium might target lead associated with specific materials (such as organic matter, carbonates, or iron or manganese oxide), it might also capture other material; that is, the separation is not clean. Coupling that problem with changes in the lead species leads to imprecision in the method. The accuracy of a series of selective extractions has been assessed by comparing them with direct spectroscopic analyses—such as x-ray absorption spectroscopy, x-ray fluorescence, Raman spectroscopy, and other advanced analytic methods (Scheckel et al. 2005; Hayes et al. 2009; Hayes et al. 2012)—that provide information on chemical bonding of lead. In a study of mine tailings from Leadville, CO, coupling of direct characterization of lead speciation that used x-ray absorption spectroscopy with a series of selective extractions revealed discrepancies between lead fractions targeted in extractions and lead speciation determined spectroscopically and demonstrated substantial redistribution of lead after extraction treatment (Ostergren et al. 1999). However, despite their limitations, selective extractions are useful for assessing the relative reactivity of lead in different soil fractions that can then be compared with other soil layers or other sites and sources. For example, particle-size separations and selective extractions were used with x-ray absorption spectroscopy and x-ray fluorescence to determine lead speciation and mineral phases in core samples from weathered mine tailings to assess the potential for wind transport of particles and their relative bioaccessibility (Hayes et al. 2012). More advanced spectroscopic methods for chemical speciation might also be useful but can be difficult to access or can require specific expertise for data acquisition or analysis; a comprehensive summary of potential techniques is provided in D'Amore et al. (2005).

Source-Associated Tracers

The final source-attribution approach for soils encompasses a wide array of methods, including multielement analysis and methods that involve stable isotopes other than lead; they have been used to determine the contribution of lead from multiple sources on the basis of composition of the geologic materials with which lead is associated. The methods hold considerable promise but have not been extensively applied to the specific problem of lead-source attribution. For example, cadmium and zinc are commonly associated with and recovered during the

[2]Selective extraction is an analytic process in which lead is leached from a sample with a solution to recover only a specific form of lead.

Copyright National Academy of Sciences. All rights reserved.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

processing of lead ores (Rehkämper et al. 2011). As the ore is smelted, light isotopes of zinc and cadmium preferentially exit with the exhaust; heavy isotopes of zinc and cadmium are preferentially retained in the smelting residue (Sivry et al. 2008; Mattielli et al. 2009; Miller et al. 2015). The differences might then be used to track the deposition of emitted smelter particles, including lead-containing particles, over the region by analyzing the zinc and cadmium isotopic composition of the soils (see, for example, Cloquet et al. 2006; Mattielli et al. 2006, 2009; Shiel et al. 2010; Thapalia et al. 2010). Similarly, stable zinc and copper isotopes were used by Thapalia et al. (2010) to identify smelter emissions in lake sediments and thus trace lead to the smelter emissions.

In other cases, elemental ratios have been an easy means of tracing lead sources. Zota et al. (2011) used the association of lead, zinc, cadmium, and arsenic to identify particles originating from chat, and manganese was used to identify particles from uncontaminated soil. To elucidate whether pesticides or paints were responsible for enriched soil lead, Nezat et al. (2017) used the As/Pb ratio in particles to denote pesticide contributions and Pb/Ba/Zn ratios for paint contributions. Given the use of antimony in alloying processes at specific smelters, Eckel et al. (2002) found Sb/Pb ratios, as opposed to As/Pb or Zn/Cd ratios, to correlate with soil lead contributions from smelting operations.

Analytic methods have also been paired with modeling to attribute sources, and the following discussion provides several examples of such approaches for source attribution. An example of combined analysis and modeling is the use of SEM–EDS to develop a hierarchical cluster analysis for household-dust apportionment based on particle size and element ratio (Hunt et al. 1992). A combination of multiple analytic methods, extractions, and geospatial modeling was used to characterize iron oxide phases, fine-grained mine waste, and organic material that adsorbed lead (and other metals) and to distinguish relative contributions from two geochemically distinct sources, mine drainage and mine-waste pile runoff (Schaider et al. 2014). Simple mass-balance models—an example of which is provided in Chapter 5—can also help to constrain potential source contribution and aid in source attribution. More sophisticated predictive statistical models can also be useful in lead-source attribution. Contributions of soil lead from an automotive-battery recycling facility were compared with lead-based house paint and other background sources by Small et al. (1995); they used scaled deposition estimates from atmospheric dispersion to develop a statistical model that characterized observed soil-lead concentrations and attributed sources relative to the urban background. Multielement models noted in the next section on sediments might also be applicable to lead-source attribution in soils.

SEDIMENTS

The committee's investigative strategy for sediment is shown in Figure 4-4 and provides a guide to the effective determination of the natural and anthropogenic sources of lead found in river sediments. Similar analytic methods can be applied to nearly any type of sediment, such as those associated with lakes, wetlands, peat bogs, and coastal or estuarine environments. In fact, it is common to analyze sediments from different types of settings to provide a more holistic assessment of inputs of lead to the environment. Nonetheless, the focus here is on rivers and river sediments.

The sequence of analytic methods is intended only as a guide and might need to be adjusted to fit the site or operable unit of interest given specific site conditions, availability of instrumentation, and considerations of cost and time (see Box 4-2). The discussion that follows provides a general description of the methods shown in the figure and highlights some advantages, disadvantages, and sources of uncertainty. Additional information on each method can be obtained from the references provided.

Site Characterization and History

As applied here, site characterization is the process of collecting data to describe the river basin in terms of its physical, hydrologic, physiographic, and biotic characteristics at the time of the analysis and in the past. The exact list of measures to be used will depend on the site conditions but should include the identification of all natural and anthropogenic lead sources in the site and in the basin upstream of the site. The objective is to document the location and spatial distribution of each source, the form of the lead and associated materials in each source, the pathways and processes through which lead could enter a river from each source, and, for anthropogenic sources, the history and methods of lead use or processing. Most of the data required for site characterization will probably have been collected through the Superfund remedial investigation and feasibility study.

Fluvial Geomorphic Analysis and Sampling

Rivers can be viewed, simplistically, as networks of channels that transport water and sediment from upstream areas to downstream areas of a basin. Rather than being simple conduits, however, they are highly dynamic features in which water is continuously eroding and depositing sediment in the river channel and on the floodplain during floods. Erosion and deposition of sediment can incorporate sediment-associated lead that enters the drainage network into riverbed and floodplain (bank) deposits. The deposits vary widely along the river valley in their areal extent, age, and sedimentologic characteristics, such

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

BOX 4-2 Examples of Modifications of Investigative Strategy

Figure 4-4 is provided as a guide to the effective attribution of lead in river sediments in or adjacent to Superfund sites. The investigative strategy will ultimately depend on a host of factors, including the nature of the lead sources, the size of the area under investigation, the available analytic capabilities, and constraints on time and money. Thus, the strategy will probably need to be modified by selecting methods that possess a high probability of being effective for a specific site or operable unit. For example, the Maritsa River in Bulgaria is highly contaminated by lead and other trace metals. Contamination of the river is related to the inflow of mining and smelting waste from multiple mining districts in its tributaries. Bird et al. (2010a) demonstrated that the various ore bodies in the basin and the mine wastes associated with the ore bodies exhibit a distinct lead isotopic signature. As a result, lead-isotope data could be used to apportion lead between the mine or smelting wastes and the local bedrock. Lead isotopes could not, however, be used to apportion lead in riverbed sediments of the larger Maritsa River because lead was derived from many more sources, including multiple ore bodies and bedrock types. The occurrence of multiple lead sources precluded the use of simple mixing models. Bird et al. (2010a) circumvented the problem by determining the relative percentage of sediment in the Maritsa River derived from each tributary and using multi-element fingerprinting. By treating, the tributaries, including those contaminated by mining operations, as distinct sources of sediment and sediment-associated metals, the authors were able to estimate the relative quantity of sediment and, by association, metals contributed to the Maritsa River by each tributary. They were also able to estimate changes in tributary contributions downstream along the river.

The Rio Loa, which is in the Atacama Desert of northern Chile, provides another methodologic example (Miller et al. 2013a). The Rio Loa is highly contaminated by lead and other metals and metalloids. The predominant sources of metal contamination include large copper mines and their tailings piles in the Rio Loa basin and the El Tatio geyser basin. Lead isotopes could not be used to differentiate between lead from the mines and the geyser basin, although they could be used to distinguish between lead from the mines or geysers and non-mineralized rocks in the area. Current studies suggest that the most effective method for sediment and sediment-associated metal apportionment is the ratio of copper (which is high in mining wastes) to antimony (which is high in sediments of the geyser basin). The abundance of heavy minerals also appears useful.

as particle size, shape, lithology, and color. The sources of sediment and lead in the deposits also vary along the river and on a local (stream segment) scale.

The primary objective of analyzing a river's erosional and depositional history is to identify, characterize, and map the distribution of distinct, time-correlated sedimentary deposits along the river valley. The analysis provides an understanding of the transport pathways through which sediment-associated lead is dispersed from suspected lead sources and the potential sites where lead might have accumulated along the river during specific times. It also provides a framework that is essential for developing a sound sampling program for which the physical and chemical analyses described below can be effectively conducted. For example, sediments deposited before European settlement might provide information on natural concentrations of lead associated with the sediments in the river basin.

Lead Isotopic Analysis

When applied to river sediments, the assumption is that lead in riverbed, floodplain, or terrace deposits represents a mixture of lead from all the sources that contribute lead to the river at the time of sediment deposition. Comparison of the lead isotopic composition of the sediment mixture with the isotopic composition of the suspected sources allows an estimation of the relative contribution of lead to the sediments from each potential source. The analysis is often complicated because the lead in river sediment is derived partly from the bedrock that underlies the basin. Depending on the basin's geology, the lead isotopic composition of the underlying bedrock might vary substantially between rock units. Thus, in addition to the suspected anthropogenic sources of lead, it might be necessary to consider multiple bedrock lead sources.

Nonetheless, many studies have used lead isotopic methods effectively to identify the source of lead in river deposits directly (Church et al. 2004; Miller et al. 2007; Shepherd et al. 2009; Bird et al. 2010a,b; Ayrault et al. 2012). Lead isotopic methods have also been applied to various other sediment types, such as those associated with reservoirs and lakes (Shirahata et al. 1980; Petit et al. 1984; Graney et al. 1995; Chiaradia et al. 1997; Foster et al. 2002; Callender 2005), wetlands, and peat bogs (Shotyk et al. 1998; Weiss et al. 1999; Marcantonio et al.

Copyright National Academy of Sciences. All rights reserved.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

2000; Cloy et al. 2008). Lead isotopes have been particularly useful in deciphering the contributions of lead from nonmineralized rocks and mining and milling wastes and contributions of lead from distinct mining districts when the lead isotopic characteristics vary between ores (see, for example, Bird et al. 2010a,b). However, when the isotopic characteristics of the mining wastes are similar to those found in the local, mineralized, but unmined bedrock, it will not be possible to attribute lead to those sources by using lead isotopes.

The analysis of river deposits differs from the analysis of upland soils (described in the previous section) in two ways. First, the isotopic composition of river deposits of known age can be determined and compared with suspected lead sources in the basin for that time. In doing so, it might be possible to construct a history of the changes in lead source contributions to the river over periods of decades to centuries. Second, spatial variations in lead concentration and isotopic data can be combined to assess changes in lead source longitudinally along the river valley. For example, Shepherd et al. (2009) analyzed a variety of geologic materials along an 86.5-km segment of the River Wear in northeast England (Figure 4-5). At Site 1, the $^{208}Pb/^{206}Pb$ ratio in riverbed sediment was comparable with that in geologic materials found in a mineralized ore body and was therefore interpreted as reflecting the relatively high lead concentrations associated with historical mining operations. The decline in downstream concentrations between Sites 1 and 5 was thought to result from dilution and the deposition of dense, finely milled lead particles in the riverbed. Farther downstream, $^{208}Pb/^{206}Pb$ ratios continue to decline until reaching Site 9, whereas lead concentrations increased. The decrease in $^{208}Pb/^{206}Pb$ ratios presumably reflected the influx of mine waste from two tributary valleys where lead ore was derived from a second mineralized zone in the ore body; this second mineralized zone was characterized by a lower $^{208}Pb/^{206}Pb$ ratio. Shepherd et al. (2009) used changes in lead concentration and $^{208}Pb/^{206}Pb$ ratios between Sites 10 and 27 to assess the influx and importance of additional sources of

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

lead to the river. The key point is that combined spatial analysis of lead concentration and lead isotopic composition of the river sediments might provide a more detailed understanding of source contributions of lead to a river than is possible by using lead concentration data alone.

Spatial and Temporal Analyses

If the use of lead isotopes fails to determine the source of lead in river sediments completely, it will be necessary to apply one or more additional methods. Spatial and temporal analyses have been effective in determining lead sources qualitatively in many river basins and are described below.

Spatial Analysis

One of the most extensively used methods for determining sources of lead in rivers is examination of the spatial distribution of lead concentrations or elemental ratios, such as Pb/Zn, in alluvial deposits. The initial interpretation is that an abrupt downstream increase in lead concentration or the ratio of lead to another element will correspond geographically to a predominant source. There are several advantages to the approach, including that it can be applied to both riverbed and floodplain deposits, it can be completed relatively rapidly by using samples collected during a single sampling campaign, it relies on standard analytic procedures for the analysis of total lead concentrations, and the data are relatively easy to interpret.

An example was provided in Chapter 3 (Figure 3-3) for lead, zinc, and antimony concentrations along the Rio Chilco–Rio Tupiza drainage system of southern Bolivia (Villarroel et al. 2006). In the United States, Integral (2014) and Pavlowsky et al. (2010) used spatial variations in lead concentrations in channel sediments along the Big River to assess lead sources. Figure 4-6A shows that lead concentrations increase abruptly downstream of river mile 110, presumably in response to the influx of mining-related waste materials as the river passes through the St. Francois County Mining Area. Lead concentrations decrease downstream until reaching the Meramec River. However, the general decrease in concentration is disrupted locally by minor increases in lead concentrations (Figure 4-6A). Integral (2014) argued that those minor increases in lead

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

concentration downstream of river mile 85 reflect less important additions of lead from other mining operations, including lead from the Barite Mining District.

Although the analysis of spatial patterns in lead concentrations and elemental ratios provides insights into the sources of lead in river sediments in the drainage basin, it has several limitations as described below.

- Multiple sources might exist in a specific area, and it might not be possible to differentiate inputs between multiple overlapping sources by using lead concentration data alone. For example, the input of mining wastes might spatially correspond to areas of mineralized rock where relatively large quantities of natural lead might also enter the channel. Exploration geochemists have applied similar spatial analyses to rivers to identify the location and grade of ore deposits. To help alleviate the problem, downstream variations in other elements or in lead ratios (such as Pb/Zn) might be used to gain additional insights into the source of the lead if the concentrations of such elements differ between the overlapping sources. Figure 4-6A, for example, shows that barium concentrations increase substantially downstream of river mile 85; a trend that Integral (2014) argues is related to the influx of barite from mining operations in the Barite Mining District. Alternatively, the analysis of downstream trends in elemental concentration might focus on a specific sediment size fraction, as shown in Figure 4-6B, which is associated with a known lead source, such as tailings.
- The resolution of the downstream trends in lead concentrations reflects the number of samples that are collected along the river and the location from which the samples were obtained. Differences in sampling frequencies and locations can yield differing results. For example, Figure 4-6 shows the downstream trends in lead concentrations developed by Intergral (2014) (Figure 4-6A) and Pavlowsky et al. (2010) (Figure 4-6B). Differences in the trends in lead concentration are related primarily to differences in the sampling scheme and approach used, which lead to differences in interpretation of the primary source of lead to the Big River.

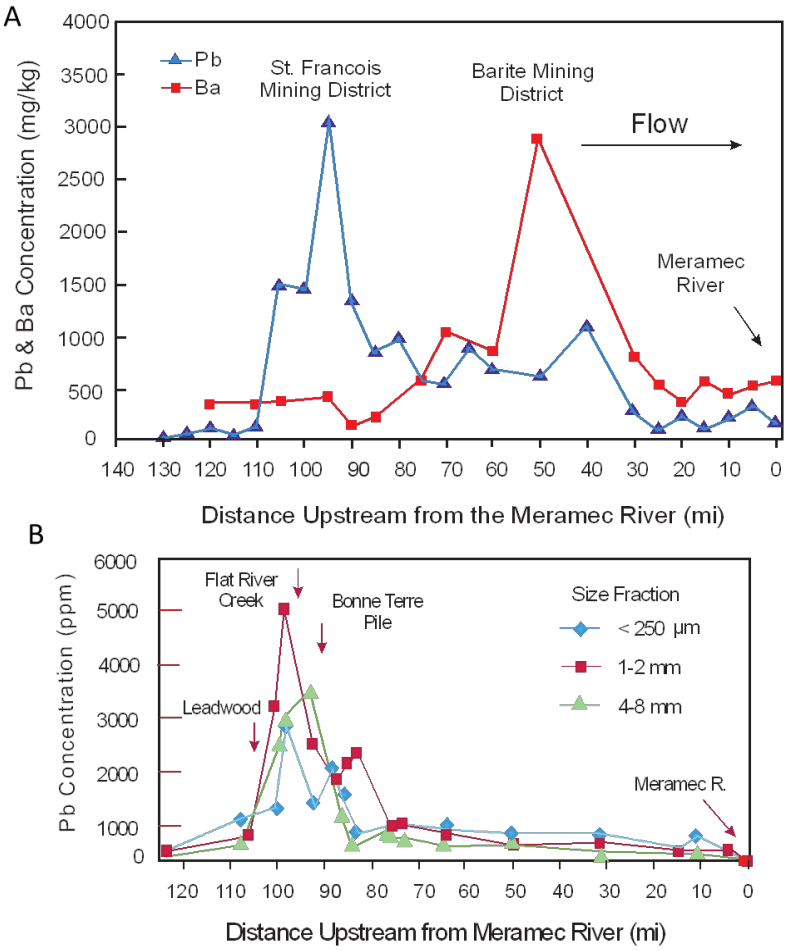

FIGURE 4-6 (A) Changes in lead and barium concentration along the Big River as determined by Integral (2014). Abrupt downstream increase in lead concentration has been interpreted as reflecting the input of mine-associated lead in the St. Francois Mining District. Increased barium and minor increases in lead presumably reflect the input of sediment from mining wastes in the Barite Mining District. Source: Adapted from Integral (2014). (B) Changes in lead concentration along the Big River as determined by Pavlowsky et al. (2010); data are stratified by grain size. Source: Adapted from Pavlowsky et al. (2010). Differences in developed trends partly reflect differences in sampling frequency and location.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

• Abrupt downstream variations in lead concentrations might reflect erosional and depositional patterns along the river rather than a location of lead influx. Stream segments that are characterized, for example, by relatively wide valleys, low gradients, and gentle flows are often areas of sediment-associated lead deposition. That deposition can lead to zones of high lead concentrations; thus, abrupt increases in lead concentration are not always a perfect indicator of a lead source.

• The method cannot be used to determine the quantity of lead inputs into a system from a specific source. Rather, it provides a means of assessing the relative importance of lead inputs from a given source.

Temporal Analysis

Floodplains and terraces are composed of sediments that are deposited directly by the river adjacent to the channel (Figure 3-4). In contrast with upland areas, anthropogenic lead in floodplains and terraces often extends to depths measured in meters. The spatial distribution of sediment-associated lead in these alluvial deposits reflects the depositional processes responsible for floodplain formation and the sources and concentrations of lead in the river at the time of deposition. The floodplain and terrace deposits therefore contain a historical record of lead inputs (Macklin et al. 1999, 2006). Once deciphered, this stratigraphic record can be compared with documented variations in lead-related human activities to help to determine the potential role of anthropogenic lead sources in contaminating the river environment. The lead-related human activities should be described in terms of their time of operation, spatial extent and location, quantity of potential lead inputs into the river, and the geochemical and physical character of the contaminated sediments (Heim and Schwarzbauer 2013), all of which are to be collected as part of the site characterization described above.

The methods, assumptions, and uncertainties inherent in developing a chronology of trace-metal inputs (including lead) into a river are outlined in Macklin and Klimek (1992), Hudson-Edwards et al. (1997), Tobin et al. (2000), Miller and Orbock Miller (2007), Pease et al. (2007), Du Laing et al. (2009), Bábek et al. (2011), Matys Grygar et al. (2011, 2012, 2013), and Ferrand et al. (2012). In general, it involves documenting the physical characteristics of the river deposits, sampling and analyzing the deposits for lead and other substances, and applying absolute dating methods to estimate the age of the deposits in calendar years. Absolute dating methods include a wide array of techniques, such as measurement of radioactive isotopes (such as ^{137}Cs, ^{210}Pb, and ^{14}C), optically stimulated luminescence, dendrochronology, and identification of historical artifacts; see Stokes and Walling (2003) for a more detailed discussion of these and other dating methods.

The most detailed assessment of lead and trace-metal attribution is based on the analysis of overbank deposits. Overbank floodplain deposits—also referred to as vertical accretion deposits—are produced by the deposition of suspended sediments from floodwaters that inundate the floodplain surface (Figure 3-4). The process results in layers of younger materials that bury older sediments; thus, the sediment age varies systematically with depth. Because deposition occurs only during floods, there are temporal gaps in the depositional record, and the relationship between depth and unit age is not perfect. Nonetheless, such depositional sequences often result in the construction of a relatively high-resolution history of lead loadings into the river.

The distance of a specific stream segment from a source and the number of potential upstream lead sources vary along the river valley (Figure 4-7). Therefore, it is important to develop a chronology of lead inputs into the river at multiple locations. Sites should be selected to ensure that all potential lead sources will be reflected in the constructed chronology and to minimize the number of locations needed to differentiate inputs between all potential lead sources. The historical record should also extend back hundreds to a few thousand years, if possible, to ensure that natural variations in lead loadings (those characteristic of the basin before substantial human activities) are adequately characterized.

A potential disadvantage of the approach is that multiple human activities that have the potential to increase lead influx in a river can overlap temporally. For example, early mining operations in Southeast Missouri during the late 1800s and early 1900s correlate temporally with regional land-use change, which allowed large quantities of eroded upland soil to enter the drainage network. Increases in sediment-associated lead during that time might therefore have been associated with both mining operations and regional erosion of mineralized soil that contained natural lead. In some cases, it might be possible to separate the significance of lead from such diffuse sources from that of point sources by examining spatial trends in the data.

The method also assumes that lead in the sedimentary deposits is immobile, an assumption that is typically met (Hudson-Edwards et al. 2001). Provided that the migration of lead after deposition is negligible, the resolution of the record depends on the degree to which the sediments can be dated; when the ages of the sediments are poorly constrained, only general statements about lead sources and contributions can be made. Other causes of uncertainty are associated with spatial differences in the deposition of overbank sediments across the floodplain, variations in concentration related to flow conditions at the time of sediment deposition, and variations in the grain-size distribution and organic matter content of the sediment

Copyright National Academy of Sciences. All rights reserved.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

(both of which influence lead concentrations). In some areas, such as sites located downwind of smelters and tailings piles, the atmospheric deposition of lead might also complicate vertical trends in lead concentrations. Various methods have been developed to reduce those uncertainties, such as analyzing multiple floodplain cores at a site and normalizing metal concentrations on the basis of a specific grain size, organic matter content, or conservative element[3] (Horowitz 1991; Harrison et al. 2003; Bonotto and de Lima 2006; Miller and Orbock Miller 2007).

In addition to analyzing floodplain deposits, the approach has often been applied to sediments in the bed of a reservoir (Von Gunten et al. 1997; Kähkönen et al. 1998; Müller et al. 2000; Audry et al. 2004; Miller and Mackin 2013). The disruption of stream flow and sediment transport by a dam typically results in higher rates of nearly continuous sediment accumulation in a reservoir (Müller et al. 2000; Arnason and Fletcher 2003) and makes it easier to create a high-resolution record of historical changes in sediment and sediment-associated metal loadings into a river. In addition, thicker depositional units reduce the potential influences of the postdeposition migration of lead in the deposits (Callender 2000; Audry et al. 2004). In other cases, other types of sediments might be examined to complement the historical sedimentary record (Box 4-3).

[3]A *conservative element* is one that is uniformly distributed throughout the sampled core. If the ratio of another element to a conservative element changes with depth in the core, the change is a signal that the other element is being depleted from or being supplied to the system.

Mineralogic and Morphologic Analyses of Bulk Samples

It is not uncommon for the geologic materials associated with a lead source to contain a unique set of miner-

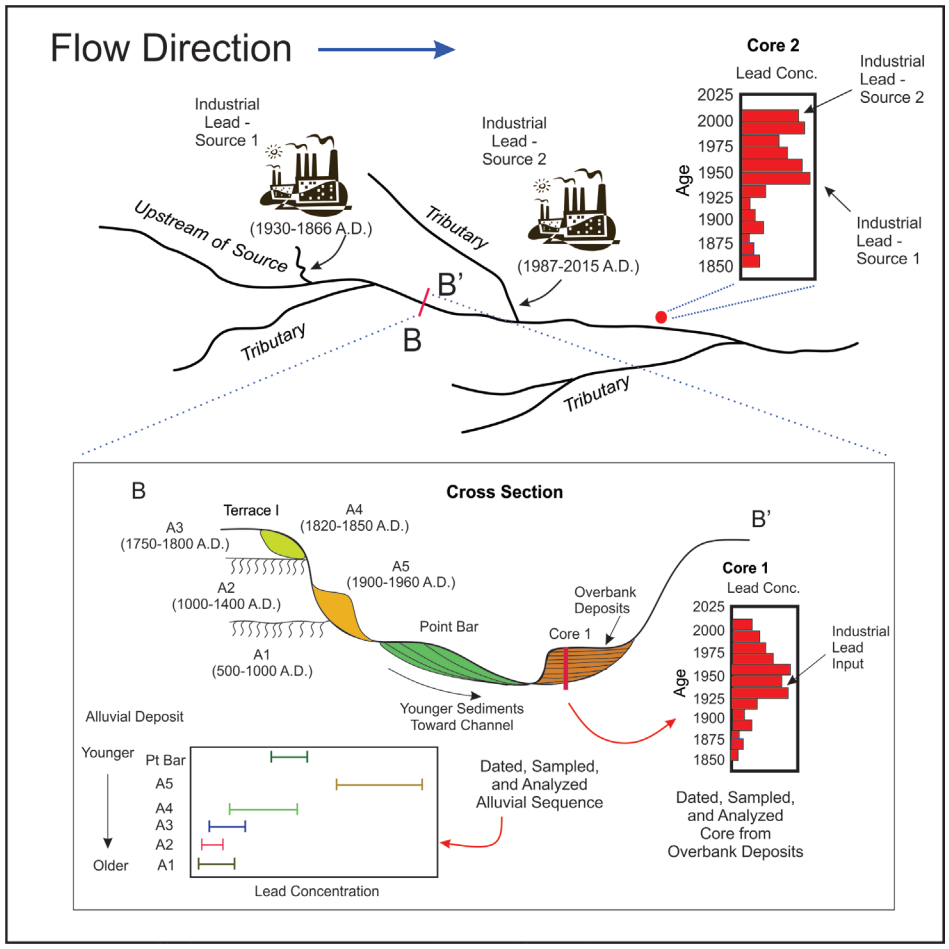

FIGURE 4-7 Schematic diagram illustrating how the age of a sedimentary deposit can be combined with lead-concentration data to determine the source of lead in river sediments. Sources are determined by linking temporal peaks in lead concentration to known anthropogenic inputs at the time of sediment deposition. Variations associated with natural inputs of lead can be assessed by examining prehistoric deposits (not shown).

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

als. Unique minerals or mineral assemblages have been used effectively to determine the origin of sediment from point and nonpoint (diffuse) sources along contaminated and uncontaminated rivers. Two of the most common analyses focus on clay minerals or heavy-mineral assemblages (Jeong and McDowell 2003; Eberl 2004; Gingele and DeDeckker 2005; Benedetti et al. 2006; Chen et al. 2009; Hardy et al. 2010; Bernárdez et al. 2012), although other mineral groups might also be useful depending on the nature of the source.

The effectiveness of the use of clay minerals stems from the fact that they reflect the composition and weathering characteristics of rock types that underlie the basin. Different rock types generally yield different clay minerals on weathering. Of importance to lead attribution in and around Superfund sites, the use of clay minerals has the potential to differentiate between sediments derived from nonmineralized rocks and mineralized or mined rock units. For example, differences in clay mineralogy were used by Jeong and McDowell (2003) to differentiate between mine tailings (enriched in the clay mineral chlorite), Ontonagon River sediments (with low chlorite and high illite), and a Wisconsin red-clay deposit (with low illite and high expandable-clay content) along the south-central coast of Lake Superior.

Heavy minerals, particularly sulfide minerals, have also been used to assess the origin of sediment and sediment-associated trace metals (including lead) in mining districts (Schreck et al. 2005; Bernárdez et al. 2012). Schreck et al. (2005), for example, found that minerals as-

BOX 4-3 Historical Analysis of Lake, Bog, and Coastal Sediments

In addition to the analysis of river sediments, sedimentary records from lakes, peat bogs, and coastal areas can provide valuable insights into the sources and magnitude of lead loadings into the environment. The analysis is similar to the methods applied to overbank floodplain and reservoir deposits in that the sediments are sampled, analyzed, and dated, and this allows the development of a record of the temporal variations in lead influx into the water body. The temporal record can then be compared with an understanding of the history of anthropogenic lead use in the region, including timeframe and extent of activity, changes in regulatory measures, and location of sources.

The input of lead and other trace metals into lakes occurs by a combination of wet and dry atmospheric deposition and the inflow of water and sediment from the surrounding drainage basin (Norton et al. 2004; Aebischer et al. 2015). It follows that the sedimentary deposits produced record changes in metal inputs from both atmospheric and basin sources. The analysis of lake sediments to determine atmospheric sources of lead deposition has been complemented by the analysis of peat bogs (Weiss et al. 1999, 2002; Bindler 2006; Kylander et al. 2009; Shotyk and Krachler 2010). Some peat bogs receive water, nutrients, and lead almost exclusively from the atmosphere; their sedimentary records are particularly useful because they are not substantially affected by either surface-water or groundwater inputs (Damman 1986; Shotyk 1988).

Assessment of lead sources in and adjacent to Superfund sites necessarily requires distinguishing local from global or regional atmospheric lead sources. Two approaches are commonly used to differentiate the two. First, multiple lakes are cored and analyzed; some receive runoff and lead from local sources, and others receive lead only from atmospheric sources. Norton et al. (2004), for example, analyzed the sedimentary records contained in three lakes in Massachusetts that were adjacent to a Superfund site. Two of the lakes received lead from their drainage basins. The third lake was in a relatively undisturbed basin and therefore received lead primarily from atmospheric sources. Comparison of data on the three lakes provided insights into the magnitude and timing of contamination of the environment by local sources.

The second, and more common, approach is to combine lead-concentration data with lead isotopic data (see, for example, Shirahata et al. 1980; Petit et al. 1984; Graney et al. 1995; Callender 2005; Aebischer et al. 2015). As presented earlier, comparison of the changes in the lead isotopic composition of the sediments can often be linked to suspected lead sources. A more recent, and potentially useful, approach is to analyze the cores for lead, lead isotopes, and other isotopes (such as zinc and iron isotopes) to assess source. For example, Aebischer et al. (2015) used lake sediments in Schefferville, Quebec, to assess the effect of mining on aquatic ecosystems. Combining lead-concentration data with lead, zinc, and iron isotopic data allowed the identification of multiple sediment sources of lead in the lake. A number of recent studies have focused on zinc isotopic records in lakes to assess the input of metals into the environment from smelting and other atmospheric sources (Sonke et al. 2002, 2008; Cloquet et al. 2006; Weiss et al. 2007; Mattielli et al. 2009; Thapalia et al. 2010).

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

sociated with the Kupferschiefer ores, which outcropped in the Mansfeld mining district of central Germany, were dominated by covellite, chalcopyrite, and sphalerite. The mineral assemblage differed from the waste materials that were associated with metalliferous flue dust and smelter wastes, which were dominated by slag particles; the differences allowed their contributions to the river to be determined. However, mineral assemblages were similar between mining wastes composed of low-grade ore and natural outcrops of the ore deposits. Determining the importance of the latter sources depended on spatial variations in the waste piles in the basin. A potential shortcoming associated with the use of heavy minerals is that weathering of the particles after deposition might alter the mineralogic characteristics of the source sediments.

Other minerals might also be used to assess sediment contributions from mining operations. In Southeast Missouri, mineral analyses showed that chat particles sampled from the Leadwood, Federal, and National tailings piles were composed almost exclusively of dolomite, whereas sediments sampled from selected control sites were composed of greater than 95% chert and feldspar. Pavlowsky et al. (2010) argued that the quantity of dolomite in the Big River was an indicator of the relative contribution of mine tailings to the river.

The structure of fine-grained sediment is often examined to help to identify minerals. In other cases, the shape of such fine-grained sediments might provide direct insights into sediment and sediment-associated lead sources. As noted above, particles emitted from smelters are often spherical; that knowledge combined with an understanding of their composition can determine their source.

The structure of larger particles in rivers is typically the product of their degree of weathering at their source, abrasion during transport, and modifications after deposition. In general, the farther a particle has been moved along the river, the more rounded (smooth) it is. Thus, particle shape provides information on transport distance and the potential source in the basin (de Boer and Crosby 1995; Cardona et al. 2005). In mining areas, the mechanical grinding and crushing processes associated with the production of mill tailings might create particles characterized by a broken, jagged appearance that can differ from that of sediment derived from natural sources in the basin and allow their identification.

Mineralogic and Morphologic Analysis of Particle Separates

Because of the processes involved in the erosion, transport, and deposition of sediment in river systems, it is possible that sand-sized or dense particles will be derived from a source different from that of the light and fine-grained particles, such as silt and clay (see, for example, Miller et al. 2013b). Thus, the identification of lead source by using mineralogic, chemical, or isotopic methods might be complicated by analyzing mixed population of particles that differ in size or density. It might be possible to alleviate the problem by collecting and analyzing separates of the bulk sediment, which are characterized by a narrow range of particle size or density.

Multielement Fingerprinting and Modeling

The use of multielement geochemical fingerprinting techniques has increased in recent years (Franks and Rowan 2000; Collins et al. 2012, 2013; Rowan et al. 2012; Miller et al. 2015). For example, multielement methods have been applied to suspended sediments (Walling and Woodward 1995; Collins et al. 1997, 2001; Massoudieh et al. 2013), riverbed sediments (Collins et al. 2013; Evrard et al. 2013), floodplain deposits (Collins et al. 2012), and sediments in lakes, reservoirs, and wetlands (Miller et al. 2005, 2013b; Pittam et al. 2009; Rowan et al. 2012). The increased use has been promoted by recent advances in analytic techniques, such as inductively coupled plasma–mass spectrometry, that allow the rapid analysis of large numbers of elements at a reduced cost and by the ability to determine the source of contemporary and historic sediments and sediment-associated lead.

Conceptually, it is assumed that as sediments (and their associated lead) are eroded and transported from a source or source area they are combined with sediments from all other sources in the basin to form a mixture. The geochemical composition of the mixture depends on the composition of the source materials and the relative proportions of sediment derived from each source, provided that the physical and chemical characteristics of the sediment are not altered during transport, as might occur by elemental leaching or changes in the sediment grain size. If the compositions of the source materials and the mixture in question are determined (measured), it is possible to estimate the relative proportions that each source contributed to the mixture (Box 4-1).

Single and multielement geochemical fingerprinting in rivers has been used most extensively to determine nonpoint sources of sediment and sediment-associated contaminants in a river, whose sources might be defined by soil type, underlying geologic units, land-use categories, or tributaries (Russell et al. 2001; Douglas et al. 2003; Miller et al. 2005, 2015; Collins et al. 2009). In mining areas, the approach might provide insights into the quantity of lead eroded from mineralized upland soils. Multielement fingerprinting has not often been applied to point sources of contamination, such as a tailings pile, but it has been shown to be effective when it has been applied (Bird et al. 2010a,b).

The application of statistically based mixing models to river sediments has been criticized because the models can generate vastly different results that have similar

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

levels of uncertainty, particularly when contributions from a source approach 0 or 100 % (Collins et al. 2010; Rowan et al. 2012). Much of the uncertainty is associated with variability inherent in the physical and geochemical characteristics of the source materials and the river sediment. To reduce and quantify uncertainty inherent in the modeling results, recent studies have explored the use of an increasing suite of statistical approaches, including the use of Monte Carlo sampling frameworks and Bayesian methods (Franks and Rowan 2000; Small et al. 2002, 2004; Collins et al. 2010, 2012, 2013; Rowan et al. 2012; Cooper et al. 2014; Nosrati et al. 2014; Miller et al. 2015; Palazón et al. 2015). The analyses have led to a general agreement that current attempts to apportion sediment and sediment-associated metals that use inverse (unmixing) models should include a sensitivity analysis for the input parameters and a detailed assessment of model uncertainty.

Other Source-Associated Tracers

In addition to the methods described above, a number of other characteristics have been used effectively to attribute sediment and sediment-associated metals in river sediments. They include magnetic properties (Yu and Oldfield 1993; Maher et al. 2009; Armstrong et al. 2010; Guzmán et al. 2010), particle color (Croft and Pye 2004; Martinez-Carreras et al. 2010), chemical speciation (Macklin and Dowsett 1989; Shikazono et al. 2012), and isotopic analyses, such as analyses of isotopes of strontium and neodymium (Weldeab et al. 2002; Padoan et al. 2011; Rosenbauer et al. 2013), copper (El Azzi et al. 2013), mercury (Blum and Bergquist 2007; Foucher et al. 2009; Sonke et al. 2010; Mil-Homens et al. 2013; Blum et al. 2014) and zinc (Sivry et al. 2008; Chen et al. 2009). Although the latter isotopes have not been applied extensively to the problem of lead-source attribution, their application holds considerable promise. Elements that have unique isotopic characteristics as a result of smelting, such as cadmium and zinc, might be particularly useful.

Modeling of Upland Erosion, Sediment Yields, and Transport

A wide array of surface-water modeling routines of varied degrees of complexity have been developed and applied to rivers to understand and predict sediment and sediment-associated contaminant-dispersal processes from both point and nonpoint sources. In general, the models are not designed specifically to determine the source of lead in river basins, and their successful application often depends on the availability and quality of topographic, hydrologic, geologic, and other forms of data. Given those constraints, the wide array of models available, and the ability to combine different models for specific purposes, the committee chose to exclude them from its investigative strategy. Nonetheless, such models might provide important insights into the source of sediment-associated lead. For example, in addition to known point sources of lead in and around a Superfund site, diffuse sources of natural lead exist in a river basin. The occurrence of lead in mineralized soils, which are eroded and delivered to a river during runoff events, might be particularly important in Superfund sites associated with mining districts. It might therefore be important to assess the contributions of lead derived from diffuse upland sources by erosion and mobilization processes. That objective might be addressed partly through the application of spatially distributed models that determine the location and magnitude of upland erosion and the amount of sediment that leaves the basin mouth. The distributed models typically partition the drainage basin into small parcels, each characterized by its own conditions, such as soil type, slope, and vegetation. Those data can then be used to assess soil mobilization and delivery to the river from specific parcel types, such as a specific type of soil or bedrock unit.

GROUNDWATER AND SURFACE WATERS

As noted in Chapter 3, concentrations of dissolved lead are typically low in surface waters or groundwater with a pH of 6-8. Thus, concentrations of dissolved lead tend to be relatively low in areas characterized by carbonate rocks (limestone and dolomite), such as in Southeast Missouri, that buffer pH near neutral and limit acid generation associated with the weathering of sulfide minerals, such as pyrite and galena, found in lead-bearing ores. The concentrations can be high in acidic water in other mining areas where limestone and other rock types that can neutralize acid water are generally not present. Here, the committee presents its investigative strategy for groundwater and surface waters (see Figure 4-8) and provides a brief discussion of the methods. The analysis of lead associated with water particles has been discussed in previous sections on soils and sediments.

Site Characterization and Hydrologic Conceptual Model

A first step in determining lead sources in water is to identify and characterize possible sources in and adjacent to the site. For example, if the focus is on river water, potential sources upstream of the site should be identified with potential on-site sources. Once possible sources are located, a conceptual model of the potential dispersal pathways via surface waters and groundwater can be developed by using existing data and standard hydrologic and hydrogeologic approaches. The conceptual model should address questions whose answers might depend on whether lead was found in groundwater from a well,

Copyright National Academy of Sciences. All rights reserved.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

in surface water from a river, stream, lake, or pond, or in both. Possible questions to consider include, What surface-water bodies are downgradient of the potential lead sources and thus might receive dissolved lead from the source? Do the adjacent streams receive groundwater that originates from the vicinity of the lead source? Is river water derived primarily from surface-water runoff, tributaries, or groundwater, and do these contain lead sources? What geologic materials come into contact with the groundwater and its flow path, and how do they influence flow (for example, limestone vs sandstone)? What are the depth to groundwater and the slope of the groundwater surface, and what are the sources of groundwater recharge? What are the vertical and lateral directions and rates of groundwater flow? Are there important anthropogenic sources of lead, such as lead-containing paint or plumbing, at the site that might dissolve and contribute to lead in water?

Once the conceptual model has been developed, it should be possible to define which sources can contribute lead to groundwater and surface waters. In some cases, such a hydrogeologic assessment might lead to a confident conclusion about the source of the dissolved lead that obviates further study. For example, a suspected lead source might be downgradient of a water-sampling location and be eliminated as a possible source, whereas an obvious upgradient source might be implicated if other lead sources are eliminated.

Groundwater and Surface-Water Sampling

If the conceptual hydrogeologic analysis does not elucidate the source with sufficient confidence, additional investigations are necessary. The sampling of groundwater should reflect the directions, depths, and rates of flow relative to the suspected lead sources and use accepted sampling protocols (see, for example, USGS 2006). Wells selected for sampling should accurately reflect the water chemistry of the hydrogeologic system under investigation and yield samples suitable for water analysis. At a given site, a sufficient number of appropriate wells for sampling or sufficient historical sampling data might not be available. Various factors can influence the integrity of a groundwater sample, and such characteristics as well

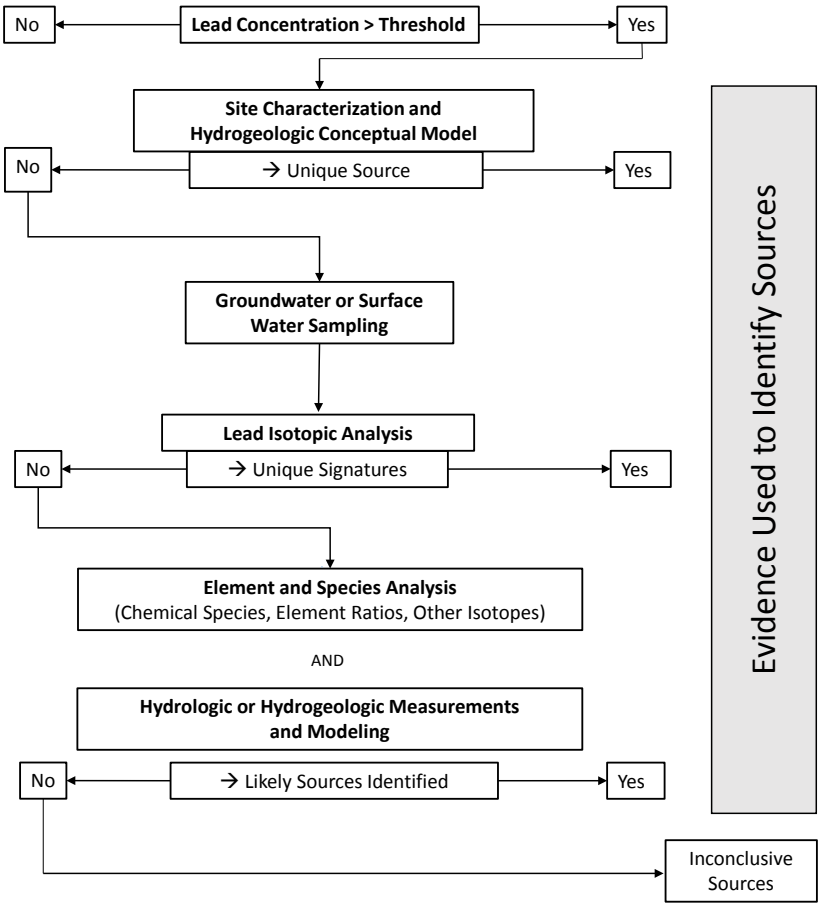

FIGURE 4-8 Example of an investigative strategy for attributing sources of lead in water at a Superfund site. The optimal sequence will depend on site-specific conditions, availability of analytic techniques, and cost and time considerations.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

type, depth to groundwater, water-sampling depth based on the location of the well screen, pumping rate, water yield, temperature, pressure, and amount of suspended particulate matter (PM) should be considered in the sampling strategy. Wells that are not frequently pumped, such as monitoring wells, should be purged of standing water by pumping before sampling. If dissolved concentrations are of interest, water samples are filtered through a 0.45-μm pore-size membrane and analyzed for lead and other constituents. If total concentrations are desired, unfiltered and acid-digested samples are analyzed. Given the generally low lead concentrations in surface waters and groundwater, all sampling and filtration equipment should be lead-free. All water-sample handling, preservation methods, and storage before analysis should follow standard protocols for trace metals to avoid changes after sampling that might affect measured concentrations (EPA 1996a; Lurry and Kolbe 2000).

In rivers, two approaches to sampling are often used to characterize concentrations and sources of dissolved lead. First, samples are collected at multiple times at fixed locations to characterize temporal variations in lead inputs into the river, particularly during changes in flow or flood events. A monitoring station established along a river has the potential to collect multiple samples as water levels rise and fall during a flood event. Second, one or more synoptic sampling campaigns might be conducted along river segments of interest; synoptic sampling is sampling of a river at many locations at the same time. The samples are obtained from the main channel and all known inflow points—such as tributaries, culverts, irrigation ditches, and urban sewer systems—along the river during a relatively short period of stable flow. River flow (discharge) is also measured so that the amount of lead (mass/time) that passes any point along the river can be calculated from the product of lead concentration (mass/m^3) in the river and flow (m^3/time). Thus, the analysis provides a snapshot of the variations in elemental concentrations and load along the river that can then be interpreted by using mass balances and inferred or observed lead inputs.

Methods for sampling standing bodies of water, such as lakes and ponds, are generally similar to those used for rivers although strategies for the timing and location of sample collection might differ. The number of samples to collect, the distribution of sampling locations, and the interval between sampling events should be determined on the basis of the size, depth, inflow and outflow points, water residence time, seasonal variations, and study objectives for the particular water body. For example, samples collected at the inflows and outflows of the lake or pond might be compared with representative samples collected from the interior. Sampling as a function of depth in different locations might provide information about water mixing or settling of PM that might affect concentrations. Depth sampling is usually done with a sampling device that is dropped on a weight to a desired depth and opened or closed with an activator. If it is important to assess changes in water chemistry as a function of time, time between samplings of lakes or ponds might be much longer than times between samplings of rivers and will depend on the residence time of the water and possibly on seasonal variations.

Lead Isotopic Analysis

As discussed above, lead isotopic abundances have been used extensively to determine the potential sources of lead in a wide array of media, including water. Specifically, a quantitative comparison is conducted between the isotopic signature of lead in water and possible sources, such as ores, tailings, nonmineralized rocks, and other lead-containing materials in the area. Some lead isotopic data might be available in the published literature. As noted, the method requires that the isotopic signatures of the possible lead sources be sufficiently different to warrant measurement of lead isotopes in water samples. That is, if all the possible sources of lead have the same isotopic signature, an expensive time-intensive isotopic analysis might not be appropriate (Aberg 2001; Komárek et al. 2008; Norrström and Knutsson 2012). If the known isotopic signatures of sources show that isotopic analysis might be useful, an unfiltered water sample could be digested for analysis of lead concentration and isotope ratios to determine the sources of lead in the water. The investigation might include application of a mixing model or other computational analysis. There might not be a unique isotopic signature, but the analytic results could add to the body of evidence and help to eliminate some sources. A total lead measurement includes dissolved lead and lead associated with suspended particles (Graham et al. 2006). A more in-depth analysis of lead isotopes in a filtered water sample (0.45 μm or smaller filter pore size) vs the particles retained on the filter might provide additional source information if the two fractions differ in their lead isotopic signatures.

Element and Species Analysis

If the isotopic signatures of the total, dissolved, or particulate lead do not yield a unique match to one or more of the lead sources or if more data are desired to build confidence in the lead-source attribution, further analysis of constituents in water will need to be undertaken. A first-order assumption is that high lead concentrations will occur at or immediately adjacent to a source and decrease with distance from the source as a result of dilution and a variety of attenuation processes. As noted in the soil and sediment sections, spatial variations in element concentrations and concentration ratios can provide qualitative insights into lead sources by identifying characteristic

Copyright National Academy of Sciences. All rights reserved.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

associations or ratios. Single-element and multielement analyses and measurement of dissolved chemical species and water-quality characteristics can be undertaken on surface waters and groundwater. For example, total, dissolved, and particulate samples could be analyzed for major, minor, and trace elements; for species, such as sulfate or phosphate; and for total dissolved carbon and organic carbon content. Standard measurements of water include temperature, conductivity, pH, dissolved oxygen, oxidation–reduction potential, and alkalinity (acid-neutralizing capacity) or acidity (base-neutralizing capacity). Stable isotopes of water (^{18}O, ^{16}O, ^{1}H, and ^{2}H), dissolved noble gases (^{4}He, ^{20}Ne, and ^{40}Ar), tritium (^{3}H), sulfur hexafluoride (SF_6), and radiocarbon (^{14}C) are among the tracers used to determine groundwater sources, flow paths, and water age (Clark and Fritz 1997; Cook and Bohlke 2000). Measurements of elements, species, isotopes, and water characteristics help to bound geochemical and hydrologic models that can predict water sources, flow paths, mixing, and reactions.

The chemical composition of particulate samples can be determined directly as discussed above or calculated on the basis of the difference between the measured total concentration and the dissolved concentration. Element ratios and element associations can then be compared with possible sources. Lead that is associated with particulate organic matter, for example, might point to an organic-rich water-body source. If filtered particles can be recovered, the particle size, structure, mineralogy, and composition could be investigated with SEM, XRD, or other techniques discussed above to provide insight into suspended-particle sources.

Hydrologic and Hydrogeologic Measurements and Modeling

Modeling of River Samples

Analysis of synoptic samples and temporal variations in lead concentrations can help to identify sources along rivers (Kimball 1997; Boughton 2001; Nimick and Cleasby 2001; Wirt et al. 2001; Walton-Day et al. 2005; Kimball et al. 2002, 2005, 2006, 2007, 2010; Church et al. 2007; Kimball and Runkel 2009). In most cases, the samples are obtained from the river channel and all known inflow points—such as tributaries, culverts, irrigation ditches, and urban sewer systems—during relatively short intervals of stable flows, which are also measured. The analysis provides a snapshot of the variations in elemental concentrations and loads along the river that reflect points of substantive elemental (lead) inputs. Instantaneous load is calculated as the product of constituent (lead) concentrations and river discharge at the sample point at the time of collection. Downstream variations in the loads in the river channel are used to determine the importance of each inflow point as a lead source and to determine the attenuation of lead along the river. Sources are identified by using a mass-balance approach that compares the cumulative load within the river channel with the cumulative load that enters the channel from upstream inflows (see, for example, Kimball et al. 2002). In many cases, the approach is combined with the use of elemental tracers, such as lead isotopes, to quantify more fully the contributions of a pollutant from a specific source.

An advantage of the synoptic approach is that the location and importance of unsampled, diffuse sources of lead from groundwater, which are often poorly documented, can be determined. A disadvantage of synoptic sampling is that it is difficult to apply during some periods of high river flow, but methods are being developed to overcome such issues (see, for example, Kimball et al. 2010). In some cases, the data collected during synoptic sampling can be used for in-stream modeling of solute transport, such as that of dissolved lead (Gooseff et al. 2008). An understanding of temporal variations in lead concentration at a site during a flood event can provide insights into the primary sources of contaminants (McDiffett et al. 1989; Evans and Davies 1998; House and Warwick 1998; Lloyd et al. 2016).

Geochemical, Hydrologic, and Hydrogeologic Models

Developing an overall assessment of sources of lead in water at a given site requires integration of multiple lines of evidence from isotopic and chemical measurements with hydrologic or hydrogeologic data. The data are typically analyzed and evaluated by using various statistical, numerical, and modeling approaches of varied complexity. Multivariate statistical methods, such as principal-components analysis or factor analysis, might be used to identify correlations or characteristic patterns among elements or species. Mixing models use differences in chemical or isotopic composition among the potential sources to determine whether the composition of a specific water can be represented by a mixture of the potential water-source compositions. Inverse mass-balance models compare differences in mass composition to deduce whether a specific water was derived from another along a flow path in contact with minerals and gases (Zhu and Anderson 2002). That model approach assumes a chemical steady state (no net change in chemical species) and is based strictly on mass differences and mass transfer between water and the minerals and gases that are assumed to be in contact with it. Mass-balance models also typically ignore hydrodynamic dispersion or diffusion processes that might affect solute concentrations (Zhu and Anderson 2002). Although potentially informative, mass-balance models consider net chemical mass differences and do not produce a unique solution; that is, multiple combinations of water types, minerals, and gases

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

might fit the water composition in question and depend on the water, mineral, and gas phases assumed in the model.

Models that rely solely on mass differences are distinguished from chemical-speciation models that rely on mass balances and thermodynamics to establish the dominant chemical reactions and chemical species that are present. On the basis of thermodynamic equilibrium constants and kinetic parameter estimates, chemical-speciation models are able to calculate the dominant aqueous species and complexes, the amount of dissolution and precipitation of minerals, the solubility of gases in water, and the extent of surface sorption reactions. Several programs are available and include free packages, such as PHREEQC (Parkhurst and Appelo 1999) and MINTEQA2 (EPA 1999a). Chemical equilibrium calculations, particularly ones that include sorption reactions, can help to elucidate possible chemical reactions that lead to mobilization of lead from sources or how lead might be attenuated along a flow path. For example, streams contaminated by lead, zinc, and cadmium from mine waste runoff and mine-drainage discharge in the Tri-State district in Oklahoma, Missouri, and Kansas were studied with a combination of runoff and discharge measurements by using a conservative tracer, statistical analyses, mass-balance calculations, and equilibrium chemical modeling to evaluate lead sources, metal fluxes, and chemical reactions that mobilize or attenuate lead downstream of waste piles and mine-drainage input (Carroll et al. 1998; Schaider et al. 2014).

A variety of water-quality modeling routines might be applied to rivers, such as the Water Quality Assessment Simulation (Ambrose et al. 1988), which includes methods to model advection, dispersion, and point and diffuse mass loading processes and can be linked to hydrodynamic and sediment transport models to assess flow and particulate transport. For groundwater, hydrologic gradients, pump tests to calculate aquifer storage and characteristics, tracer studies to map flow paths and determine residence time, and geologic and hydraulic information are used to support aquifer and groundwater basin models. A widely used package is MODFLOW, the US Geological Survey three-dimensional finite-difference groundwater model (Harbaugh 2005). Originally developed solely as a groundwater-flow simulation code, MODFLOW has been greatly expanded to include simulation of coupled groundwater and "surface-water systems, solute transport, variable-density flow (including saltwater), aquifer-system compaction and land subsidence, parameter estimation, and groundwater management" (Brovelli and Moreno 2014). Surface-water or groundwater models are increasingly used in conjunction with analysis and modeling of chemical and isotopic data to provide a comprehensive evaluation of contaminant sources, transport, and transformation at a study site (Appelo and Postma 2005; Bedekar et al. 2016).

AIR

Like the investigative approaches presented for soils, sediments, and water, attribution of sources of airborne lead typically requires field assessment, laboratory analysis, and modeling. The laboratory analysis of lead-containing PM that might be collected by air monitors is similar to the laboratory analysis of soils described above. Therefore, the committee focuses here on field assessment and modeling approaches that are used to distinguish sources of airborne lead. The committee's investigative strategy is a tiered approach illustrated in Figure 4-9; each tier increases in complexity to achieve source attribution. Tier I begins by conducting chemical speciation on archived filter remnants after lead analysis has been conducted, Tier II includes field sampling to develop site-specific source signatures for input into receptor modeling, and Tier III includes more complete ambient and source sampling to provide additional evidence via a combination of source-dispersion and receptor modeling. Although the focus here is on traditional particle analysis, other approaches are possible. As noted above, Prapaipong et al. (2008) used oak trees to determine dispersion of lead emissions from a smelter, and other researchers have used lichen, rainfall, and snowpack sampling to understand spatial gradients of emissions from smelters and other sources (see, for example, Carignan and Gariepy 1995; Simonetti et al. 2000; Spiro et al. 2004; Telmer et al. 2004; Aznar et al. 2008; Graney et al. 2012; Graney and Landis 2013; Sherman et al. 2015).

Two types of models are used in the committee's investigative strategy. First, receptor models start with pollutant concentrations measured at receptors and attempt to identify and quantify contributions of different sources on the basis of source characteristics (Watson et al. 2016). Specifically, receptor models analyze patterns of chemical composition, particle size, temporal variability, and spatial gradients that are related to specific sources and take into consideration measurement uncertainty and source variability to determine contributions from specific sources that reach the receptors (Watson et al. 2002; Watson and Chow 2005, 2013, 2015; Watson et al. 2016). Second, source-dispersion models start with emission estimates related to potential sources—such as surface soils, road dust, and mine tailings—and calculate meteorologic transport of pollutants to receptors. The receptors are usually neighborhood, urban, or regional air-quality monitoring sites that are established to determine compliance with ambient air-quality standards. The US Environmental Protection Agency (EPA) maintains the Web site Support Center for Regulatory Atmospheric Modeling (SCRAM), which describes EPA-accepted air-quality models in great detail and provides free downloads for the accepted model software.[4]

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

Tier I: Analyze Composition of Archived Filters

The first tier in the committee's investigative strategy involves further analysis of samples that have already been collected from air-monitoring stations. As noted in Chapter 3, high airborne lead concentrations in total suspended particles (TSP) at monitoring sites of the Missouri Department of Natural Resources (see Figure 3-6) indicate the presence of lead-contaminated resuspended dust in the Southeast Missouri Lead Mining District (MO DNR 2016). Archived filter-sample remnants for which 24-hour TSP lead concentrations exceeded 0.15 $\mu g/m^3$ could be submitted for PM composition analyses, which could include multielement analysis (Watson et al. 1999) with XRF, inductively coupled plasma–atomic emission spectroscopy, and inductively coupled plasma–mass spectrometry; analysis of anions (such as chloride, nitrate, and sulfate) and cations (such as water-soluble sodium, magnesium, potassium, calcium, and ammonium) with ion chromatography; and thermal-optical carbon analysis of organic and elemental-carbon and thermal-carbon fractions. Lead concentrations should be compared with those reported by the Missouri Department of Natural Resources for quality assurance. Material balances of measured species should be performed to ensure that all major PM components are measured, that is, that the sum of the measured chemical species adequately explains the gravimetric mass (Chow et al. 2015).

High ambient PM lead concentrations might have various sources. Watson et al. (2016) recommend that additional indicators be obtained from archived filter-sample remnants to reduce source apportionment uncertainties. Such indicators include commonly found mineral-related elements (aluminum, silicon, potassium, calcium, and iron), elements related to mining activities (such as lead, zinc, copper, arsenic, and silver), stable lead isotopes (^{204}Pb, ^{206}Pb, ^{207}Pb, and ^{208}Pb) that can be analyzed after hot-block acid digestion procedures (with a combination of nitric, hydrochloride, and hydrofluoric acids) established by EPA for lead analysis with inductively coupled plasma-mass spectrometry (EPA 1996b, 1999b). Contaminated fugitive dust might be the main contributor to atmospheric lead concentrations, and additional measurements—such as the carbonate carbon and rare earth elements (such as cerium, dysprosium, erbium, europium, gadolinium, holmium, lanthanum, lutetium, neodymium, praseodymium, samarium, terbium, thulium, and ytterbium) and particle structure—can also be considered.

Descriptive data analysis can be conducted to understand PM composition and to examine temporal and spatial variations. Comparison of similarities and differences between lead-isotope ratios and abundances of rare earth elements among sites serves as the starting point for examining site-to-site and month-to-month variations (Felix et al. 2015). Because chemical composition varies with geologic source as illustrated in Figure 4-10, that information can be used in source attribution to define source categories. Receptor modeling of about 200–300 samples with the Effective Variance Positive Matrix Factorization and UNMIX solutions to the chemical-mass balance equations can be conducted to identify and quantify major source contributions of PM and lead (EPA 2016).

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

Preliminary source contributions can serve as a guide in determining the type of source signatures that need to be acquired in Tier II and the extent of field sampling needed for Tier III.

Tier II: Establish Source Signatures for Receptor Model Input

Figure 4-11 illustrates the strategy for establishing source signatures. Source signatures of major source types—such as vehicle exhaust, aircraft fuel combustion, lead smelting, and glass manufacturing—from the EPA source-profile library (SPECIATE; EPA 2017a) can be compiled with the available local source signatures to evaluate the adequacy of signatures for receptor modeling. Geological materials are often a major source of PM mass, so site-specific source signatures probably need to be defined. Surface-soil and paved-road dust surrounding sampling sites that are not in compliance with air-quality standards for lead should be collected, processed, and resuspended in a laboratory resuspension chamber into TSP, PM_{10}, $PM_{2.5}$, and PM_1 size fractions by using multiple filter substrates that will accommodate the same chemical speciation as that of archived filter-sample remnants for Tier I identification. For residential areas that have high lead concentrations, soil samples and house lead-based paint chips should also be collected, processed, and resuspended. Additional bulk-material sampling and analysis of storage piles, tailings piles, and mine haul roads that are near sites that have high lead concentration should also be considered. The source signatures identified here in Tier II serve as model input and verification for receptor modeling and as the basis of development of a speciated PM emission inventory for source-dispersion modeling (EPA 2016).

Tier III: Conduct Additional Field Sampling and Analysis for Source-Dispersion and Receptor Modeling

EPA's National Emissions Inventory (EPA 2017b) shows that lead from mining constitutes only 10% of Missouri emissions, but processes or activities that result in resuspended dust emissions are not well represented in current emission factors (EPA 1998). Because source-dispersion models use emission factors to translate emissions into ambient concentrations, the modeling results can be variable. To improve the accuracy of receptor and source-

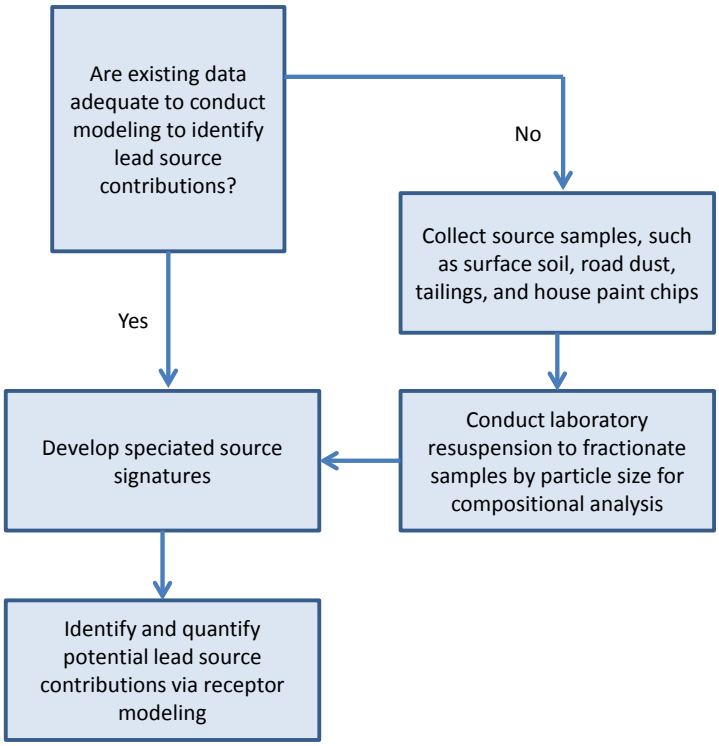

FIGURE 4-11 Expansion of the committee's Tier II strategy for establishing source signatures to inform receptor modeling that can help to identify and quantify potential lead sources.

dispersion models, field sampling is necessary to provide site-specific inputs. Thus, the committee's strategy for Tier III that is illustrated in Figure 4-12 includes varied field sampling to improve model inputs. For source-dispersion models, sensors that are mounted on-board a moving vehicle can be used to determine mechanical suspension and surface loadings (Kuhns et al. 2001), and portable wind tunnels can be used to measure wind erosion potential in various PM size fractions (Etyemezian et al. 2007; Sweeney et al. 2008; Wang et al. 2015). Source-dispersion and receptor models can both benefit from use of site-specific meteorologic variables, such as wind speed and direction, temperature, and relative humidity. Particle-size distributions illustrated in Figure 4-13 vary by geologic source categories and can be obtained by using an optical particle counter that provides particle-number concentrations in several size ranges, such as 0.01–10 μm. Finally, particle mass and chemical composition of lead and other geologically abundant elements (such as aluminum, silicon, potassium, calcium, iron, zinc, and titanium) can be determined by using a cascade impactor.

As indicated in Figure 4-12, model reconciliation can be used to identify uncertainties and limitations in receptor and source-dispersion modeling results and to improve model input datasets (EPA 2007). The goal here is to establish how well the receptor concentrations predicted by a source-dispersion model agree with the measurements collected at receptors and to assess whether receptor-model output compares favorably with the available information on source locations and signatures. Another approach is to use source-dispersion models in a parametric mode to predict chemical patterns at a receptor and then to use receptor models to identify the patterns that best reproduce the ambient measurements (Watson and Chow 2014).

Implications for Southeast Missouri and Research Needs

In this report, the committee has described potential sources of lead contamination, transport mechanisms for environmental dispersal of lead, and investigative strategies for determining the sources of lead in environmental media. Here, the committee addresses specifically the implications of that information for the Southeast Missouri Lead Mining District, provides some research recommendations for optimizing approaches, and considers other opportunities for using some of the analytic techniques or methods for identifying potential sources of environmental lead contamination.

IMPLICATIONS FOR SOUTHEAST MISSOURI

Given the extensive mining history of Southeast Missouri, determining the sources of lead at sites in this region is complex. The presence of lead-ore deposits at or near the surface means that there are natural sources of lead at sites. Mining activities have produced waste materials, and the materials have been dispersed over wide areas, have been deposited many miles from their sources, and have come into contact with residential areas. A further complication is that lead can come from consumer products, including lead paint, gasoline, agricultural chemicals, batteries, and plumbing materials. In Chapter 4, the committee described various analytic methods and approaches for identifying sources of lead at a site and presented investigative strategies for implementing the various methods and approaches for soil, sediments, water, and air. As noted, the steps undertaken can depend on site characteristics and available resources. In the pages that follow, the committee first presents its overall conclusions regarding implementation of its strategies for Southeast Missouri and then provides two case studies that use data from the area to support its conclusions.

Overall Conclusions

Isotopic analytic techniques hold great potential to distinguish commercially processed lead or non-native ores from natural or locally mined materials in Southeast Missouri.[1] For example, compilation of published $^{206}Pb/^{207}Pb$ ratios in North American ore deposits, gasoline, and paints is described in the next section. On the basis of those results, it is likely that lead-isotope ratios will be able to be used to apportion the sources of lead in soils, sediments, or house dust between those commercial sources and natural or mined materials in the case of Southeast Missouri. One strength of using isotopic analysis is that it can pinpoint a source with high accuracy if there is a unique signature, as is the case, for example, in the lead-paint data described in the next section.

The use of the analytic methods in the investigative approaches to distinguish natural sources of lead from mined material is much more challenging and might not be possible, particularly for soil, in the absence of a unique isotopic signature. The natural and mined material often contains lead that exhibits similar isotopic values, and this inhibits the use of lead isotopes to determine source. It might therefore be necessary to use other methods alone or in combination as shown in the committee's investigative strategies to make a judgment about potential sources. Accordingly, determining the grain size, structure, and composition of soil particles might link them to a source. For example, analyzing structure and chemical composition could link soil particles to a smelting operation inasmuch as smelter-derived soil particles often contain spherical grains composed of sulfides, oxides, or glassy particles (Ettler 2016). The spatial distribution of the particles is also likely to vary as a function of wind direction and distance from the smelter; sulfides are relatively dense, and their concentration in soil is therefore likely to be higher closer to the smelter. Furthermore, differences in particles from tailings and chat piles might be determined partly on the basis of grain size; the former consists of relatively small grains (less than 74 μm), and the latter

[1]The committee uses the term *natural materials* to refer to the geologic background that includes the mineral deposits that have not been mined.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

much larger grains (often 4–8 mm). In addition, concentrations of barium and barite might distinguish lead from the Southeast Missouri Barite District and the St. Francois County Mining Area. With time, however, weathering of soil minerals derived from primary ore or smelter sources might alter or dissolve them and potentially disperse lead as a sorbed species or substituted in minor amounts in new precipitated phases. The point is that the selection of specific characteristics for attribution must be based on physical, compositional, mineralogic, or geochemical differences in the various source materials, and it might be necessary to use multiple methods to differentiate between all sources present. Even when multiple analyses are used, however, source identification might not be definitive.

It might be possible to estimate the relative contributions of lead from sources by using data analysis. *Data analysis* is a catchall term for mathematical manipulations designed to extract useful patterns and narratives from empirically derived collections of numbers, or data sets. The assessment activities undertaken early in the Superfund process described in Chapter 1 typically generate substantial collections of such data. The field collection and laboratory analysis of samples follow quality-assurance protocols; consequently, the consistent quality of the resulting data makes them well suited to systematic analyses.

A concrete example of data analysis to help to establish the extent to which lead-based paint contributes to environmental lead contamination in the Southeast Missouri Lead Mining District is described as the second case study. The mass-balance analysis revealed that much less total lead is likely to reside in exterior paint on older houses than in the top 1 inch of soil in many Southeast Missouri residential yards. Consequently, the contribution of exterior paint is expected to be a small fraction of the average lead content measured in typical Southeast Missouri residential yards. Such data analysis can be used to determine the dominant contributors to the mass balance of lead at a given site. However, the committee emphasizes that lead paint could still be the most important source for human exposure. The committee did not examine exposure pathways to determine the most important source for human exposure.

Lead-Isotope Techniques: A Southeast Missouri Case Study

To use lead-isotope ratios effectively for source attribution, one must first determine the lead isotopic composition of the various potential sources. The technique works well if there is an isotopic contrast between the sources that one wishes to distinguish but can yield equivocal results if there are overlapping isotopic compositions in the various potential sources. In most cases, some potential sources can be eliminated, and the investigation can focus on fewer possible sources. Thus, the lead-isotope method should work for source attribution of lead in soil near residences in mining or smelting areas if the isotopic composition of the ores and tailings is distinct from that of other possible sources.

For this case study, the committee selected lead paint and gasoline as possible sources because widespread environmental contamination has resulted from their use. The committee assessed whether they could be distinguished from natural ores or tailings from Southeast Missouri. It is well known that the lead isotopic composition differs between various ore deposits (Stanton and Russel 1959) and between lead ingots and slags and contaminated soils associated with different mines (Rabinowitz 2002). Different gasoline producers and paint manufacturers used lead mined from different ore bodies and in some cases changed their sources through time (Rabinowitz and Hall 2002). Therefore, it is expected that in some specific cases the lead isotopic composition of gasoline and paint might differ from that of local ore bodies but in other cases might be the same and therefore not useful for source attribution. The lead ores from Southeast Missouri have an extremely unusual lead isotopic composition (Rabinowitz and Wetherill 1972; Goldhaber et al. 1995). Thus, the isotopic composition of lead mined from Southeast Missouri (and adjacent areas in the tristate region) appears to be distinct from lead mined in nearly all other major mines (and products made with that lead) in North America (Doe 1970). However, the local geologic background lead in Southeast Missouri also contains unusual lead, so it might not be possible to differentiate between background and mine-derived lead in Southeast Missouri on the basis of isotopes alone.

The committee compiled $^{206}Pb/^{207}Pb$ ratios for North American lead ores, gasoline, and paints from around the world. The compilation is shown in Figure 5-1. All the data are from peer-reviewed published articles except those from the Herculaneum smelter and nearby houses, which come from an exposure-investigation report prepared by the Agency for Toxic Substances and Disease Registry (Orloff 2002). In that report, two houses that were within 1 mile of the smelter were studied. The upper panel in the figure shows that Southeast Missouri ores, especially those from the Old Lead Belt, have considerably higher $^{206}Pb/^{207}Pb$ ratios than nearly all other North American ores that are plotted; only ores from the Upper Mississippi Valley District have overlapping lead-isotope ratios. In addition, 11 of the 12 samples of paint from the two houses sampled near the Herculaneum smelter in Southeast Missouri had $^{206}Pb/^{207}Pb$ ratios lower than dust, ore, and slag sampled at the nearby smelter, and one had a higher ratio. Thirty-one samples of paint pigment produced by six major US lead-paint manufacturers had ratios lower than dust, ore, and slag sampled at the

Copyright National Academy of Sciences. All rights reserved.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

smelter. The single high-ratio paint sample was from the exterior of the back door of a house within 1 mile of the Herculaneum smelter. Either that paint contained lead that was produced from Southeast Missouri ores or the back door was contaminated by lead emitted from the smelter. Lead concentrations of the paint were not given in Orloff (2002), so the possibility that the back-door paint had low lead concentration and that the isotopic composition reflects the addition of lead from the nearby smelter cannot be eliminated.

The lead-isotope ratio measurements of materials from near the Southeast Missouri smelter suggest that the source of lead in most or possibly all lead paint was not Southeast Missouri lead. The middle panel in Figure 5-1 shows the $^{206}Pb/^{207}Pb$ ratios for six studies of lead in paint sampled from houses in other US locations, including Massachusetts, California, and New Jersey. All the samples have $^{206}Pb/^{207}Pb$ ratios lower than those of Southeast Missouri ores; this supports the suggestion that most lead paint manufactured in the United States used lead from ore deposits that did not include Southeast Missouri ores. Finally, the lower panel of Figure 5-1 shows the $^{206}Pb/^{207}Pb$ ratios of house paint from France and Brazil, road paint from New York City, bridge paint from Australia, and gasoline; these samples have $^{206}Pb/^{207}Pb$ ratios below those of Southeast Missouri ores.

Figure 5-1 shows that the Southeast Missouri ores, especially Old Lead Belt ores, have higher $^{206}Pb/^{207}Pb$ ratios than other ore deposits, gasoline, or paints compiled for North America. As noted, the only exceptions are the ores from the Upper Mississippi Valley District, which were probably not produced in large quantities in the 20th century compared with those from Southeast Missouri, and the single paint sample from the house near the Herculaneum smelter. Thus, in the case of the Southeast Missouri Lead Mining District, lead-isotope ratios will likely be able to attribute the sources of lead in soils between mined materials and paints and gasoline in most cases. As discussed below, additional analyses of lead concentrations and isotopic compositions of exterior paints in older houses in Southeast Missouri will be needed to verify the range of lead isotopic composition of paints in the area and the origin of the single back-door paint that had a high $^{206}Pb/^{207}Pb$ ratio.

The committee emphasizes that Figure 5-1 contains $^{206}Pb/^{207}Pb$ ratios from a variety of sources that were measured with a variety of mass spectrometry methods. Thus, the accuracy of the measurements varies considerably between about 0.01% and 0.5%. However, the highest estimated error is still smaller than the symbol sizes on the diagram; thus, it is clear that even without high-precision measurements, lead in most paints should be easily distinguishable from Southeast Missouri ores. High-precision lead-isotope analyses have uncertainties that are about one-fiftieth of the value reflected by the size of the symbols in Figure 5-1; thus, it is likely that at specific sites near other ore bodies, there will be measurable differences in lead-isotope ratios between paint and ore materials. In Figure 5-1, the committee showed only $^{206}Pb/^{207}Pb$ ratios because only they were available in some data sets. However, it is well known that if plots of $^{206}Pb/^{204}Pb$, $^{207}Pb/^{204}Pb$ and $^{208}Pb/^{204}Pb$ are included, there can be greater resolving power for determining isotopic source contributions.

The committee notes that lead-isotope ratio measurements can be classified into three categories according to their precision: low-precision analyses of digests without chromatographic separation using quadrupole inductively coupled plasma mass spectrometry (ICP–MS), medium-precision analyses of digests without chromatographic separation using magnetic-sector ICP–MS, and high-precision analyses of digests after chromatographic separation using either multicollector magnetic-sector ICP–MS or thermal ionization mass spectrometry. Analysis costs vary widely among laboratories but increase from low to medium to high precision. The estimated cost per analysis is $50–500 and depends on the sample type and the analytic method. In the case of the Old Lead Belt in Southeast Missouri, low- and medium-precision analyses are likely to be adequate because of the large difference in $^{206}Pb/^{207}Pb$ between paint and ore. However, high-precision analyses might in some cases allow differentiation between ores from the various different mineral deposits in the mining district. Furthermore, measurement of ^{204}Pb with high precision might be helpful for source apportionment in some cases. In general, the committee suggests that preliminary studies with medium precision should be conducted first to determine where there would be a benefit from high-precision analyses.

The committee notes that the utility of the lead isotopic methods in other mining and smelting regions in the United States has not been evaluated adequately and will depend on the lead isotopic composition of individual ore deposits and the isotopic contrast between the ores and other exposure sources, including paint. Ores from the Coeur d'Alene Idaho mining district have an unusually low $^{206}Pb/^{207}Pb$ ratio of about 1.06, which is lower than any of the paint or gasoline $^{206}Pb/^{207}Pb$ ratios that the committee compiled from the literature (Figure 5-1). Thus, in addition to the Southeast Missouri ores, Coeur d'Alene ores have $^{206}Pb/^{207}Pb$ ratios that contrast with those of paint and gasoline and should allow source-attribution studies. Furthermore, Vázquez Bahéna et al. (2017) found that in the Taxco mining district of southern Mexico the lead isotopic composition could be used to differentiate between local ores, glazed pottery, and paints. They concluded that women of childbearing age who had high blood lead and lived in the area had acquired lead predominantly from a mixture of local ores and pottery glaze.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

Data Analysis to Estimate Lead-Based Paint Contribution to Environmental Lead Contamination: A Southeast Missouri Case Study

As noted in Chapter 2, lead-based paints were heavily used in the early decades of the previous century (Mielke 1999), particularly to protect the exterior surfaces of houses and other structures from the effects of weathering. Detritus from lead-based paints is well recognized as a potential contaminant of soils in older neighborhoods, and protocols for the collection of residential soil samples distinguish drip zones where such debris is likely to collect adjacent to painted surfaces (see Figure 5-2). In addition to paint flakes and residues, drip zones can be enriched in airborne lead-containing particles deposited initially on roofs and walls and then washed off by precipitation. As Figure 5-2 indicates, samples collected in quadrants of the larger yard are intended to represent average concentrations in soils free from those influences.

Lead is considered to be relatively immobile as a constituent of soil in Southeast Missouri. Consequently, the spatial distribution of soil lead concentrations offers some indication of where exogenous lead might have been introduced and provides a strategy for attributing soil lead to point sources where releases are concentrated at fixed locations. The contributions of removal of lead-based paint in preparation for repainting and of weathering and wear of lead-based exterior paint are expected to manifest themselves as differentials in soil lead concentrations between the drip zone and the outer yard.

Figure 5-3 directly compares drip-zone with yard-average soil lead concentrations measured at 145 Southeast Missouri lots in the Focused Residential Sampling program described by Integral Consulting Inc. (2014). Drip-zone concentrations were found to be higher than yard concentrations at about 75% of homes (48 of 65) built before 1940, when lead content in house paint started to decline (Mielke 1999). The observation of higher drip-zone concentrations at older houses provides evidence that lead-based paint contributes to environmental contamination. Many other homes of all ages showed yard-average lead concentrations well above those in their drip zones, and these data indicate the presence of sources other than house paint. The mixture of positive and negative spatial concentration gradients near homes suggests that exterior paint does not generally overwhelm other sources of soil lead in the sampled neighborhoods.

A different kind of gradient that is evident in Figure 5-3 is the tendency of older houses to have higher soil lead concentrations outside their drip zones. Of the 60 residences built after 1979, 35 (58%) have yard lead concentrations below 400 mg/kg, whereas only six of 65 built

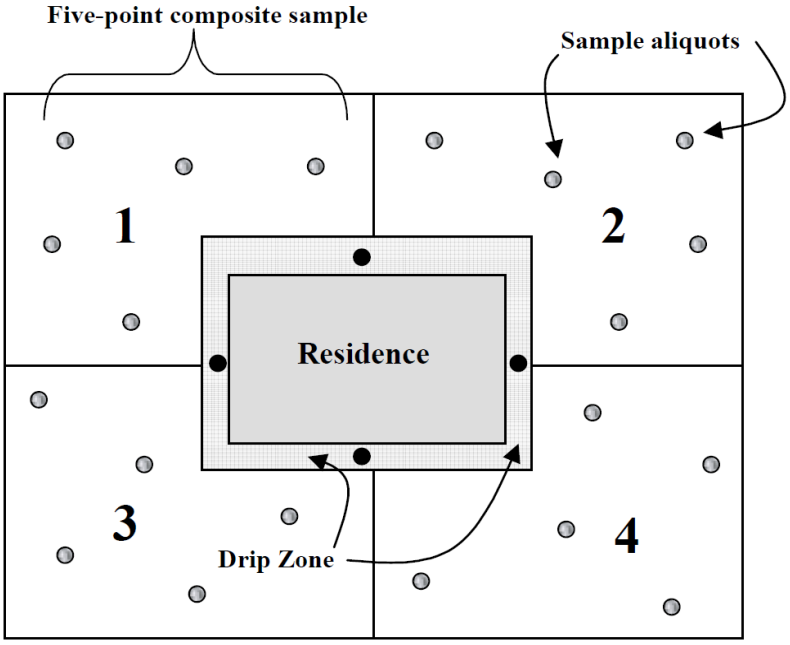

FIGURE 5-2 Recommended minimum soil sampling in yards greater than one-eighth acre. A five-point composite sample is collected 0–1 inch below the soil surface in each quadrant, outside the drip zone considered as extending 30 inches from the exterior walls of the house. Source: EPA (2003).

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

before 1940 (9%) are below this threshold. The differential could represent nothing more than the circumstance that construction at different times took place in different neighborhoods with different levels of prior contamination. Alternatively, it can be interpreted as evidence that lead-based paint debris is not confined to the drip zones of exterior walls. The higher lead concentrations recorded in older yards might be attributable in some part to the lead-based exterior paint used on the older houses, as suggested by Integral Consulting Inc. (2014, pp. 3-2, 4-1).

A mass balance can place bounds on source contributions of lead. Figure 5-3 compared *concentrations* in the outer yard with *concentrations* in the drip zone. The average lead concentration in the outer yard represents a much greater *total quantity* of lead, however, than would a similar concentration in the narrow drip zone. To assess the possibility raised above that lead-based paint is a major contributor to lead in the outer yard and not just to lead in the drip zone, the committee first considered the total lead contained in a yard's surface soil.

The total lead content of a yard's surface soil can be estimated from the average mass concentration and an estimate of soil volume and density. An arithmetic mean lead concentration of 677 mg/kg of soil was reported outside the drip zone for all Southeast Missouri yards sampled in 2013 (Integral Consulting Inc. 2014, Figure 3-8). The committee used the bulk soil density for the relevant density (Timm et al. 2005), which accounts for the volume contributed by interstitial air spaces. Surface soils vary in their composition and compaction; reported residential bulk soil densities typically are 1.2–1.6 g/cm^3. The committee took 1.5 g/cm^3 as a representative value, and this converts the mean lead concentration of 677 mg/kg reported for sampled Southeast Missouri yards to about 1 mg/cm^3 of soil. The committee assumed conservative values (lower bounds) of one quarter-acre for Southeast Missouri residential lot sizes, and 40% as an estimate of the portion covered with soil. A quarter-acre is about 107 cm^2, and the 40% soil-cover factor is offset by the sampling depth of 1 in (2.54 cm) rather than 1 cm. Those order-of-magnitude calculations yield average amounts of lead in the top inch of yard soil in a quarter-acre of at least 10 kg ([107 cm^3][1 mg/cm^3]). The 10-kg total lead burden estimated to reside in the top inch of an average Southeast Missouri yard serves as a meaningful benchmark with which the contents of other potential lead reservoirs can be compared. In the case of lead-based exterior paint, three methods described below can be used to estimate a house's total lead burden.

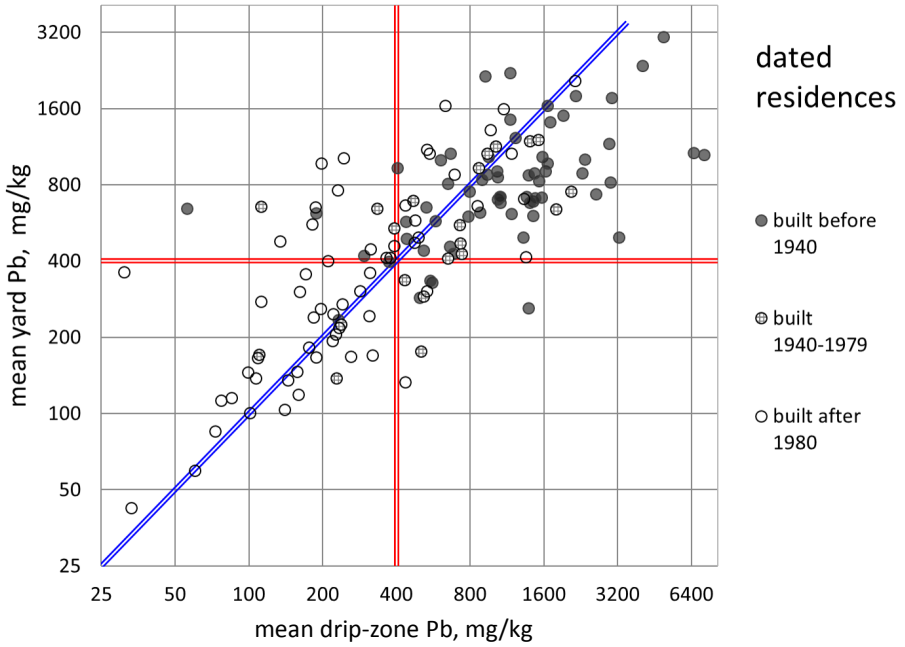

FIGURE 5-3 Results from 2013 soil sampling in Southeast Missouri. Each point represents one residential lot; its coordinates indicate drip-zone concentration (horizontal axis) and the arithmetic mean concentration of the four yard quadrants (vertical axis). The red lines indicate a typical action level for soil clean-up. Scales are logarithmic and marked at regular geometric intervals. The double blue line represents the yard concentrations equal to the drip-zone concentration. Soil lead concentrations are from Integral Consulting Inc. (2014). Only sampled residences (145 of 165) of which construction dates could be found on line from the real-estate data aggregator Zillow were plotted. Source: Generated from Zillow (2017).

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

• The lead content of house paints has varied, but a representative formulation might be the following (HUD 2012, Appendix A): 12% Pb × 50% solids × 12 lb/gal = lead at 0.7 lb/gal. A square house 40 ft on a side with walls that extend 9 ft above the foundation would have at most 1,440 ft^2 of paintable exterior surface. At coverages of 350–400 ft^2/gal, this house would take about 4 gal of paint, containing 2.8 lb = 1.3 kg. The 10-kg estimated in the surface yard soil would correspond to seven or eight full-coverage coats of lead-based paint.

• Mielke et al. (2001) studied a two-story wood frame house that was built in the 1920s and had deteriorating lead-based paint. The investigators oversaw an exterior restoration in which care was taken to collect and quantify all removed paint and reported 41 kg of paint scrapings that contained 3.7 kg of lead. They estimated that a similar amount remained bound intact to the wood, for a total of 7.4 kg of lead accumulated in paint layers over many decades.

• A third set of estimates comes from systematic national surveys undertaken for the Department of Housing and Urban Development and the US Environmental Protection Agency (EPA) by field inspectors using portable x-ray fluorescence analyzers (EPA 1995a). Table 5-1 summarizes the survey for exterior surfaces of occupied and privately owned housing units grouped into three construction periods. The historical decline of lead-based paint use is clear in the survey results. For the maximally leaded "pre-war" houses, the committee estimated total lead contents of

$$1{,}441 ft^2 \left(\frac{12\ in}{ft}\right)^2 \left(\frac{2.54\ cm}{in}\right)^2 4.6 \frac{mg}{cm^2} = 6.2\ kg,$$

which is close to the value that Mielke et al. (2001) obtained by collecting paint scrapings.

The three estimates indicate that less total lead is likely to reside in exterior paint, even on an older house, than the 10-kg average lead burden that sampling indicates now sits in the top inch of sampled Southeast Missouri yards. Table 5-1 shows that the high-lead-content paints applied before 1940 were largely still in place when inspectors visited them more than 50 years later; that finding suggests that most of the paint ever applied to the exterior remains there. Some portion of the applied paint is lost to weathering, maintenance, and wear, but most of this debris is expected to accumulate in the drip zone, as discussed earlier.

The committee's mass-balance findings imply that the great majority of the surface lead in a randomly selected sample of surface yard soil outside the drip zone cannot reasonably be attributed to contamination by paint debris in typical Southeast Missouri yards. However, they do not preclude that paint debris might be primarily responsible for the soil lead content in some areas of some yards or that the paint debris is the primary source of human exposure. Again, the committee emphasizes that one must examine exposure pathways to identify the sources important for human exposure.

RESEARCH NEEDS

Additional research provides an opportunity to enhance the performance of the analytic methods incorporated into the investigative strategies proposed by the committee and to reduce uncertainty during implementation. The committee concluded that high research priority should be given to further characterizing potential sources but notes that the research described below is not essential for implementation of its investigative strategies. The research needs are not listed in order of priority.

Characterizing Lead Isotopic Composition of Historical Paints

The committee has discussed the use of lead-isotope ratios for attributing sources of lead in contaminated soils to mining and smelting activities. The committee pointed to examples of previous studies that showed an isotopic contrast between lead from paint and lead from mining and smelting activities in Southeast Missouri and suggested that the two sources of lead in soils could be identified by using lead isotopes. However, to evaluate the utility

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

of the approach fully, additional study of lead isotopes should be conducted. In particular, knowledge of the lead isotopic composition of house paint in Southeast Missouri is limited to 11 analyses related to a single house and one analysis related to a second house, and lead concentrations in these samples were not reported. The committee recommends systematic sampling and lead isotopic analysis of paint in houses built before 1980 throughout the Southeast Missouri Lead Mining District. A broad sampling and analysis of paint in houses of various ages and locations should be conducted with at least five interior and five exterior paint samples collected from each house. That approach would give a much clearer indication of the range in lead isotopic composition of paint used in Southeast Missouri and would clarify the degree to which lead isotopes can be used in attributing lead in soil to paint vs mining and smelting sources. If there are other lead-containing consumer products at the site—such as plumbing materials, batteries, and pesticides—studies of their lead isotopic composition could establish or refute their role as a source of lead contamination at a site.

Characterizing Lead-Bearing Geologic Materials and Mining Wastes

The distribution, concentration, and geologic context of potentially key elements need to be better characterized to provide a baseline for interpretation of natural contributions to surface lead. There is a need to move away from just making bulk lead measurements and to provide greater detail on the materials and characteristics of the lead in the geologic and mining sources. Characterization would include chemical data, such as concentrations and isotopic ratios, mineralogy, grain size and texture, and host rock types. Spatial characterization would include vertical distribution, particularly in weathering (soil) profiles, and the lateral (areal) distribution over appropriate areas. Such information will improve confidence in investigative strategies for source attribution introduced in Chapter 4.

Recent advances in analytic chemistry, such as multicollector ICP–MS, have opened the possibility that a wide array of nontraditional stable isotopes can be used to determine the source of trace metals in the environment. Many metals—such as cadmium, copper, iron, mercury, and zinc—occur as sulfides and are associated with lead in geologic materials. Thus, they can potentially be used to attribute lead from geologic and mining sources in the Southeast Missouri Lead Mining District.

Variations in lead isotopic abundance in geologic materials are due mainly to radioactive decay over geologic timescales in that lead undergoes little change in isotopic ratios during other types of physical, chemical, and biologic processes. In contrast, shifts in the isotopic abundances of nontraditional stable isotopes[2] are small but are due entirely to physical, chemical, or biologic processes, including ones that occur during industrial processing or during metal dispersal at the Earth's surface (Wombacher et al. 2004; Cloquet et al. 2006; Shiel et al. 2010; Rehkämper et al. 2011; Blum et al 2014). It is that shift in the isotopic ratio that allows those isotopes to be of use in studies of source attribution. However, their effective use requires a detailed understanding of the processes that cause changes in the isotopic ratios in the environment of interest. They are more likely to change because of chemical reactions in the environment and are therefore more complicated to use for source attribution than lead isotopes. However, several such isotopes—including cadmium, mercury, and zinc—have proved useful as tracers of particles in soils and river sediments. Their application to the Southeast Missouri situation will require additional investigation but might prove to be highly useful, particularly for distinguishing between particles derived from ore deposits and smelter emissions.

Developing Capabilities to Model Metal Concentrations in Soils as a Function of Depth

As described in Chapter 4, the science of modeling sediment distributions in river floodplains is relatively advanced. Advantages of multielement, geochemical fingerprinting for attribution of sources of sediment and sediment-associated metals in rivers include (1) the ability to incorporate a wide array of elements into the analysis, thereby increasing the probability that the sources of sediment (and particulate lead) can be uniquely distinguished; (2) the establishment of widely accepted sampling and statistical analysis protocols; and (3) the increasing ability to quantify uncertainty in the attribution results (see, for example, Collins et al. 2012; Miller et al. 2015). The approach might prove applicable for determining particulate lead in sediments of the Big River with little modification of existing methods. Modeling of metal movement through soils is less developed. The application of multielemental, geochemical fingerprinting to determine sources of particulate lead in soils is more challenging because of potential alteration and dissolution of particulate lead. Theoretically, the approach is applicable to soils and might yield highly useful results, but the method will require additional testing when applied to soils. Studies could be completed on soils near known metal-emitting sources to map and model how the metals, especially lead, have moved through soils as a function of time.

[2]Nontraditional stable isotopes include elements other than carbon, hydrogen, oxygen, nitrogen, and sulfur. Examples are zinc, copper, molybdenum, mercury, iron, lithium, and cadmium.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

Characterizing Size Distribution of Suspended Particles in Air Samples

Tailings impoundments, chat piles, and smelting emissions are important sources of airborne lead in a mining district; however, little is known about the size of suspended particles and their mobility. Knowledge of the size distribution of lead-containing airborne particulate matter is important for controlling particle transport and deposition. The largest particles have high terminal velocities and can settle within a few minutes to a few hours whereas particles whose diameters are a few micrometers can remain suspended for several days and can therefore be transported long distances. Size-selective sampling of air samples in the mining district should be conducted to determine the particle-size distribution and establish the $PM_{2.5}$ and PM_{10} levels. Size-selective sampling can be conducted upwind or downwind of a source, such as smelter or tailings pile, to evaluate contributions from the source. In addition to particle-size measurements, particle analysis by elemental, mineralogic, isotopic, and microscopic methods can be used to help to relate airborne and deposited particles to their sources.

Characterizing Rates of Emission of Airborne Particles from Mining Wastes

Little is known about rates of emission of airborne lead from stockpiles of mining wastes. Portable wind tunnels can be used to estimate the airborne particle emission rates and dust production from stockpiles of mining wastes, such as chat piles and tailings impoundments. Portable wind tunnels can also be useful in measuring the threshold wind velocity at a specific site that results in particle suspension and later transport downwind. This information can help to establish whether airborne lead from mining wastes is an important source of lead contamination downwind.

Identifying Sources with Investigative Tools in Industrial Archeology and Affiliated Disciplines

Industrial archeology is the systematic study of material evidence associated with historical industrial activities, such as resource extraction and raw-material processing; refining and manufacturing; storage, transport, and distribution; uses throughout product and byproduct life cycles; and waste disposal. Although historical industrial processes were generally on a smaller scale than modern industry, they operated less efficiently, were more likely to use processes and materials that produced hazardous byproducts, and lacked pollution controls. Thus, the relative pollution effect of historical industrial activities can be highly disproportionate relative to the scale of production. Understanding historical practices sheds light on their relative importance as a source of legacy pollution that persists long after the industries have disappeared.

Industrial archeology provides scientific methods for investigating the industrial life cycle of lead and drawing objective conclusions about how past practices throughout the industrial life cycle contributed to the present abundance, distribution, and forms of lead in the built and natural environments. Those investigative tools could help to identify sources of lead contamination, especially at large Superfund sites, including the Southeast Missouri Lead Mining District, and involving industrial archeologists and historians at the earliest stages of a remedial investigation could provide valuable insight on sources, transport, and fate of contaminants. The committee notes that the investigative tools of industrial archeology evolve as do the tools of any other discipline. A good resource is *IA*, the Journal of the Society for Industrial Archeology, which publishes on industrial archeology of industrial waste.

OTHER APPLICATIONS OF RECOMMENDED ANALYTIC TECHNIQUES: A CASE STUDY OF BLOOD LEAD AND ISOTOPIC ANALYSIS

The analytic techniques and methods incorporated into the committee's investigative strategies can be used for applications other than simply soil, sediments, water, and air. For example, isotopic analysis can be used for assessing sources of lead in biologic samples, such as blood and urine. When humans are exposed to lead, the lead isotopic composition in their blood and urine reflects the sources of lead exposure. Lead isotope investigations to determine the sources of lead in residents near the Herculaneum Lead Smelter in Southeast Missouri were reported by the Agency for Toxic Substances and Disease Registry and published as two exposure investigations (Orloff 2001, 2002). The committee summarized and interpreted the data in those reports as a case study to demonstrate both the power and the complexity of the use of lead isotopes for source attribution.

Two houses within 1 mile of the Herculaneum Lead Smelter in Southeast Missouri and their occupants were sampled, and the samples were analyzed for lead isotopic composition (Orloff 2001, 2002). The various environmental media and human specimens that were sampled and their lead isotopic compositions are shown in Figure 5-4. The committee focused on the data from house 1 because the sampling included 11 paint samples, compared with only one at house 2. The patterns in lead isotopic composition and the general conclusions are similar for the two houses.

As discussed above, lead ores and mining waste from the Southeast Missouri Lead Mining District have unusually high $^{206}Pb/^{207}Pb$ ratios compared with most other mining districts and therefore most commercial

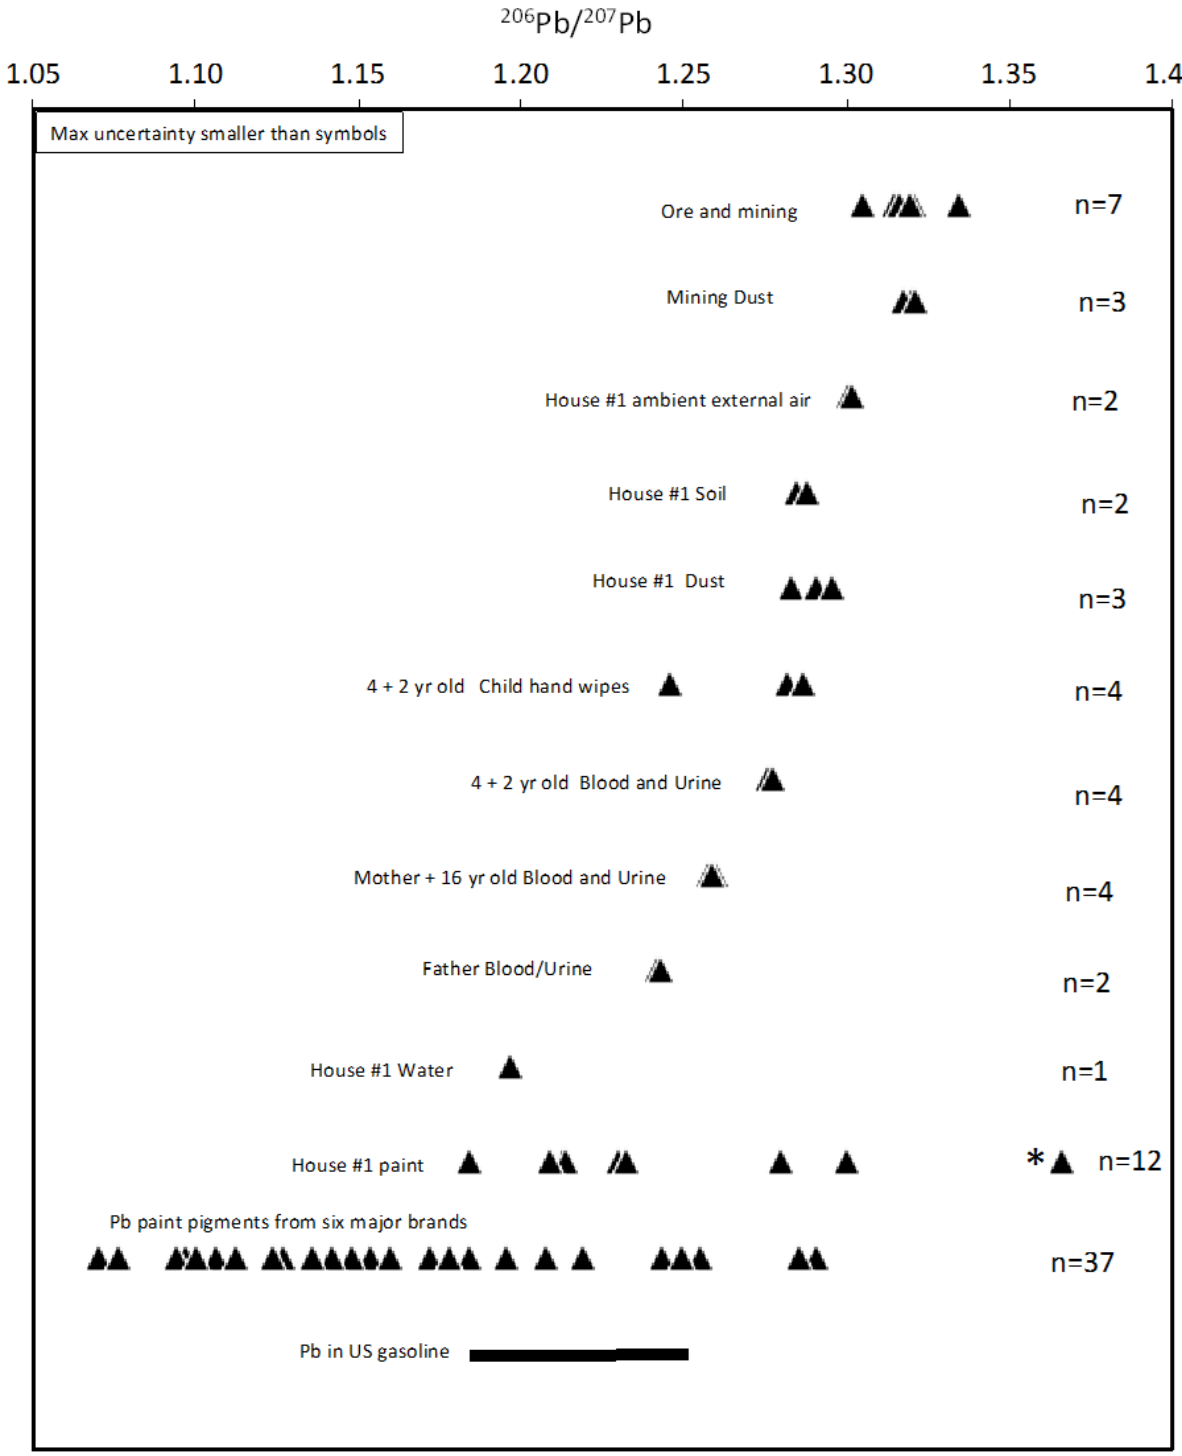

FIGURE 5-4 Compilation of $^{206}Pb/^{207}Pb$ ratios for one house within 1 mile of the Herculaneum Lead Smelter. House and its occupants were sampled, and the results were analyzed for lead isotopic composition (Orloff 2001, 2002). Also shown are $^{206}Pb/^{207}Pb$ ratios for ore and mined materials, mining dust, lead in paints and pigments of six major brands, and lead in gasoline.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

products that contain lead. Ore, mining waste, and dust generated from ore-processing at the Herculaneum lead smelter have the highest $^{206}Pb/^{207}Pb$ ratios measured (Orloff 2001, 2002), 1.31–1.34. Ambient exterior-air particles larger than 0.8 μm sampled 4–5 ft above the ground in the house 1 yard have similar but slightly lower $^{206}Pb/^{207}Pb$ ratios, 1.30, and this suggests that the lead in atmospheric dust is generated mainly from the smelter but with the addition of some lower $^{206}Pb/^{207}Pb$ lead. Lead from leaded gasoline is a ubiquitous component of soils throughout North America. Although lead was phased out of automobile gasoline by the middle 1990s, it remains in soils, especially near roadways. As discussed in Chapter 2, leaded gasoline is still used in aviation fuel, which is currently the largest source of lead emitted to the atmosphere in the United States (Wolfe et al. 2016). The $^{206}Pb/^{207}Pb$ ratio of lead in gasoline in the United States has been estimated at 1.19–1.25 (Sherrell et al. 1992; Teutsch et al. 2001). The lead-isotope ratio of a mixture of sources whose lead-isotope ratios are known scales linearly with the proportion of lead from each source. As an example of how mixing calculations can be done, the committee used data from Figure 5-1 and applied a mixing calculation to explore the origin of the atmospheric dust samples analyzed by Orloff (2001). Using average $^{206}Pb/^{207}Pb$ ratios for each sample type, the committee found that the $^{206}Pb/^{207}Pb$ ratio can be explained by a mixture of about three-fourths smelter emissions and one-fourth lead from gasoline. However, the proportion of lead derived from gasoline could be much lower if the $^{206}Pb/^{207}Pb$ ratio of smelter emissions during the period of atmospheric sampling was at the lower end of the range of ratios of Southeast Missouri ores.

Soil from the yard and dust from the interior of house 1 have lower $^{206}Pb/^{207}Pb$ ratios than atmospheric dust, 1.28–1.30. The lower values could be produced by mixing smelter lead with lead from house paint. Eleven samples of interior and exterior house paint from house 1 were analyzed. Ten had values that overlap the previously reported range of ratios of commercial paint pigments (Rabinowitz and Hall 2002), 1.19–1.30. One paint sample has a $^{206}Pb/^{207}Pb$ ratio above the range of major lead ores; it is an exterior sample, and its lead concentration was not reported, so its lead isotopic composition is difficult to interpret.

As expected from other studies, blood and urine samples from each family member yielded nearly identical $^{206}Pb/^{207}Pb$ ratios. The 2- and 4-year-old children have $^{206}Pb/^{207}Pb$ ratios of 1.28—at the lower range of soil, dust, and hand-wipe values—except for the one hand-wipe outlier that might be related to paint exposure, perhaps from a windowsill. That result suggests that the 2-year-old and 4-year-old are exposed to lead mainly via ingestion of soil and dust; this result has been found to be the case in many other studies (see, for example, Gulson et al. 1994; Gwiazda and Smith 2000; Manton et al. 2000; Laidlaw et al. 2016). The 16-year-old and the mother have lower $^{206}Pb/^{207}Pb$ ratios, 1.26, and the father has a still lower ratio, 1.24. Those results are not unexpected in that even in an adolescent blood lead can reflect a mixture of past and present lead exposure. That is, lead is stored in bone material, and blood lead can be derived partly from lead mobilization from bone over year-long timescales (Manton 1985; Manton et al. 2000).

This case study demonstrates the power of lead isotopes in differentiating between lead sources in several types of environmental and biologic media. The identification of the lead sources for a particular sample is sometimes equivocal, but some sources can be eliminated in most cases, thus narrowing the possible combination of sources that need to be considered. In the Southeast Missouri Lead Mining District examined here, the largest source of lead isotopic uncertainty is the multiple values in paint at different locations in house 1. Many paint samples analyzed in Orloff (2002) were from locations where a child would not typically be exposed to them, including above a ceiling, on a baseboard molding, and in a parent's bedroom closet. By limiting paint sampling to areas where children have access and to where paint dust is generated by friction on door jambs or window sashes, the $^{206}Pb/^{207}Pb$ ratio of paint in a given house can be estimated more narrowly. Peeling or flaking paint that can be ingested by a child presents a different problem: the amount ingested can lead to frank lead poisoning or, in a worst-case scenario, encephalopathy that results in permanent brain damage or death. Even with the uncertainties and imperfect sampling strategy, Orloff (2001, 2002) demonstrates systematic differences of lead sources from different environmental sources and allows the testing and narrowing of hypotheses for the sources of human lead exposure.

Other studies that have used lead-isotope ratios to determine potential sources of lead in children in the United States (Viczián et al. 1990; Rabinowitz 1995; Gwiazda and Smith 2000; Manton et al. 2000; Glorennec et al. 2010) have been conducted in urban areas, not near mining or smelter sites. Researchers measured lead isotopes in children's blood and then sought to distinguish between potential sources, including house paints, household dust, and soils. Most of the studies involved some individual houses where children's blood-lead isotopes match with paint or soil and some other houses where there is such a large range in paint lead-isotope ratios that no single source can be identified. One such study was carried out in Santa Cruz, CA, by Gwiazda and Smith (2000). They measured the lead isotopic composition of children's blood, household dust, exterior soil, and interior and exterior paints. In one house, paint could be eliminated as a major source of lead exposure, and exterior dust and soil were implicated. In two other houses, paint from some areas could be eliminated as possible sources, but vari-

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

ous mixtures of paints from other areas with dust and soil could explain the children's blood-lead isotope values, and no single source could be identified.

If EPA or others want to pursue blood-lead isotopic investigations for the Southeast Missouri Lead Mining District, the type of investigation described in this case study would need to be replicated in houses of different ages and at different locations in Southeast Missouri to determine where and under what conditions the lead isotope method can provide unambiguous attribution of lead sources for children who have high blood lead concentrations. The approach is promising in Southeast Missouri because the lead associated with mining and smelting has an unusually high $^{206}Pb/^{207}Pb$ ratio, about 1.34, which in most cases is distinct from lead used to make paint in the United States.

A

Challenges to Obtaining Information about Lead Sources at Superfund Sites Associated with Lead-Mining Districts

Source identification is not typically problematic for sites that have concentrated waste materials, but challenges arise when sites have large volumes of low-concentration wastes, such as large municipal landfills and mining sites. Such sites are sometimes referred to as *special sites*, and the US Environmental Protection Agency (EPA) remedial investigation and feasibility study (RI/FS) guidance "does not specifically state how… such sites should be addressed" (EPA 1988a, Section 1.5).

Lack of clear RI/FS guidance creates later challenges for assigning response costs at special sites among responsible parties and challenges to obtaining information about lead-source identification. Response costs at Superfund sites are divided among responsible parties by apportionment or allocation. Apportionment applies only when the liability of responsible parties can be separated; it would apply, for example, at a site where two parties are responsible for separate types of pollution that can be clearly distinguished qualitatively and quantitatively. Allocation applies at most Superfund sites because it is the default process and because separate liability is difficult to establish. At sites where allocation is used, equitable factors are used to assign liability for response costs. Although the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA, Superfund) does not prescribe the equitable factors to be used, Gore factors[1] are often applied and include the following:

- Ability of the parties to demonstrate that their contributions to a discharge, release, or disposal of a hazardous waste can be distinguished.
- Amount of hazardous waste involved.
- Degree of toxicity of hazardous waste involved.
- Degree of involvement by the parties in generation, transportation, treatment, storage, or disposal.
- Degree of care exercised by the parties with respect to the hazardous wastes concerned.
- Degree of cooperation with public officials to prevent harm to public health or to the environment.

Other equitable factors that have been used include contractual provisions, years of and economic benefit from ownership or operation, knowledge of and responsibility for waste handling and disposal practices, ability to pay, and strength of evidence that identifies responsible parties (Allen 2006).

EPA's orphan-share policies and guidance (EPA 1996a,b, 1997) and mixed-funding guidance (EPA 1987, 1988b) create additional challenges to identifying the sources of lead associated with Superfund sites. Orphan-share policies, such as the work policy (EPA 1996a) and the cost-recovery policy (EPA 1997), attempt to address the liability for a Superfund site that is attributed to insolvent or defunct parties that cannot pay their share of a site's cleanup cost. Here, EPA agrees to pay a portion of the orphan share allocated to insolvent or defunct parties; this can accelerate settlement with the viable responsible parties (EPA 2001). Mixed-funding is another mechanism whereby the federal government can accept settlement offers for less than the full response cost at a site. Mixed funding is appropriate under two circumstances: when pursuit of a fully funded settlement might cost the federal government more than accepting a mixed-fund settlement and when a substantial portion of the waste at a site cannot be attributed to known and financially viable parties. By creating opportunities to shift responsibility for response costs, the orphan-share policies and mixed-funding guidance create disincentives to objective disclosure of information about sources of lead at Superfund sites that are associated with lead-mining districts.

Liability for response costs at special sites, including Superfund sites associated with lead-mining districts, can range from hundreds of millions to billions of dollars. A party's ability or inability to demonstrate its contributions to a discharge, release, or disposal of a hazardous waste can substantially alter the outcome of the allocation process, orphan-share settlement, and mixed-fund settlement. The magnitude of the costs that are subject to allocation creates powerful incentives for potentially responsible parties and the federal government to think and

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

act strategically when it comes to gathering and sharing information about the sources of contamination at Superfund sites, particularly special sites. That situation creates impediments to open development and sharing of source-identification methods and results.

B

Biographic Information on the Committee on Sources of Lead Contamination at or near Superfund Sites

Edward J. Bouwer (*Chair*) is Abel Wolman Professor of Environmental Engineering in the newly formed Department of Environmental Health and Engineering at Johns Hopkins University. He is also director of the Center for Contaminant Transport, Fate and Remediation. Dr. Bouwer has extensive experience with drinking water and wastewater treatment processes, microbial process engineering, and contaminant transport and fate. His research interests encompass factors that influence biotransformation of contaminants; bioremediation for control of contaminated soils and groundwater; biofilm kinetics; biologic process design in wastewater, industrial, and drinking-water treatment; transport and fate of micro-organisms in porous media; behavior of metals in contaminated sediments; and defining and managing environmental risks. He serves as the editor-in-chief for *Biodegradation* and on the editorial boards for the *Journal of Contaminant Hydrology and Environmental Engineering Science*. Dr. Bouwer received his BS in civil engineering with a minor in nuclear engineering from Arizona State University, and an MS and a PhD in environmental engineering and science from Stanford University.

Mark D. Barton is a professor of geosciences at the University of Arizona. He serves as associate director of the Lowell Institute for Mineral Resources. He has been instrumental in driving innovative research applied to ore deposits in North America and South America for nearly 30 years. Collaborative research in which he has a leading role includes porphyry copper life cycles in the American Southwest and its broader crustal context, the regional geologic framework and origin of Carlin-type gold deposits, the characteristics and origin of iron oxide mineralization, granite petrogenesis and lithophile element mineralization in the Great Basin, and metallogenic synthesis in Mexico and adjoining regions. He is a winner of the Society of Economic Geology Lindgren Award and of the Mineralogical Society of America award and the author of numerous papers, including landmark reviews on ore deposits and metallogeny. He served on the National Research Council Committee on Basic Research Opportunities in the Earth Sciences. Dr. Barton earned his PhD in geology from the University of Chicago.

Eric A. Betterton is a University Distinguished Professor and head of the Department of Hydrology and Atmospheric Sciences at the University of Arizona. He also has appointments in the Department of Chemical and Environmental Engineering and the College of Public Health. His research focuses on air pollution, especially atmospheric aerosols and dust associated with mining operations; solar energy; rain, snow, and ice chemistry; remediation of polluted groundwater; and environmental fate of various compounds. He received a PhD in chemical kinetics from The University of Witwatersrand, South Africa.

Joel D. Blum holds the JD MacArthur Professorship and is the GJ Keeler Distinguished University Professor in the Department of Earth and Environmental Sciences of the University of Michigan. He obtained his BA from Case Western Reserve University, his MS from the University of Alaska, and his PhD from the California Institute of Technology. He was a professor of earth sciences at Dartmouth College for 9 years before moving to the University of Michigan in 1999. Dr. Blum's research focuses on the sources, fate and cycling of metals in the environment. Most recently, he has focused on understanding the biogeochemistry of mercury in aquatic, terrestrial, and atmospheric systems, in many cases using mercury stable isotopes. Dr. Blum has published over 200 research papers. He has served on numerous advisory panels for the National Science Foundation, the National Institutes of Health, the Environmental Law and Policy Center, and the Department of Energy. He is a past editor of *Chemical Geology* and current editor of *ACS Earth and Space Chemistry*. He is a fellow of the Geochemical Society, the

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

American Geophysical Union, the Geological Society of America, and the American Association for the Advancement of Science. In 2013, he won the Patterson Medal of the Geochemical Society for his work on metals in the environment.

Susan L. Brantley is Distinguished Professor of Geosciences and director of the Earth and Environmental Systems Institute at Pennsylvania State University. Dr. Brantley investigates chemical and physical processes associated with the circulation of aqueous fluids in shallow hydrogeologic settings. Her investigations incorporate field and laboratory work and theoretical modeling of observations. Particular interests are the measurement and prediction of the rates of natural processes, including chemical weathering and natural degassing. Her recent work has focused on measuring and modeling how rock turns into regolith and on water-quality issues in areas with hydraulic fracturing. Dr. Brantley has served on numerous National Research Council committees and is a member of the National Academy of Sciences. She is a recipient of the Wollaston Medal of the Geological Society, the Arthur L. Day Medal of the Geological Society of America, and the Presidential Award of the Soil Science Society of America. She received her PhD in geologic and geophysical sciences from Princeton University.

Judith C. Chow holds the Nazir and Mary Ansari Chair in Science and Entrepreneurialism and is a research professor in the Division of Atmospheric Sciences of the Desert Research Institute of the Nevada System of Higher Education in Reno, Nevada. For more than 39 years, she has conducted air-quality studies and performed data analysis to improve understanding of effects of air quality on human health, visibility, historical treasures, ecosystems, and climate. She has been principal investigator or a major collaborator in more than 50 large air-quality studies and many smaller ones in the United States and other countries. Dr. Chow is a charter member of EPA's Clean Air Scientific Advisory Committee (CASAC) and a member of CASAC's Particulate Matter Review Panel (2015–2018). She is the principal author or co-author of more than 400 peer-reviewed journal articles and book. She was chair of the Publications Committee for the *Journal of the Air & Waste Management Association* and serves on editorial boards or as thematic editor for several international journals, including the *Air Quality, Atmosphere, & Health, Aerosol* and *Air Quality Research, Atmospheric Pollution Research,* and *Particuology*. Dr. Chow has received the California Air Resources Board's 2011 Haagen-Smit Clean Air Award for her contributions to air-quality science and technology, the Air & Waste Management Association's 2016 Arthur C. Stern Distinguished Paper Award and 2002 Frank A. Chambers Excellence in Air Pollution Control Award, and the 2001 Nevada System of Higher Education's Nevada Regents' Researcher Award. Dr. Chow earned her ScD in environmental science and physiology from Harvard University.

Scott E. Fendorf is the Huffington Family Professor in Earth Sciences at Stanford University and a senior fellow at the Stanford Woods Institute for the Environment. Dr. Fendorf is interested in the chemical and biologic processes that govern the fate and transport of contaminants and nutrients in soils, sediments, and surface waters. His research group examines the chemical environments that develop as a result of biotic and abiotic processes and strives to account for the physical complexity in natural settings. Dr. Fendorf served on the National Research Council Committee on Bioavailability of Contaminants in Soils and Sediments. He received his PhD in soil and environmental chemistry from the University of Delaware.

Robert E. Hazen is a research scientist at the New Jersey Department of Environmental Protection in the Division of Science Research and Environmental Health. His research activities have focused on human health risk assessment and natural-resource management with the goal of assisting with department procedures and regulations. He has served on numerous national technical committees, including the US Environmental Protection Agency Science Advisory Board and the National Research Council Committee on Remedial Action Priorities for Hazardous Waste Sites. He received his PhD in biology and environmental health from New York University.

Chris E. Johnson is a professor in the Department of Civil and Environmental Engineering at Syracuse University. Dr. Johnson's research focuses on the chemistry of natural organic matter, which plays an important role in soil fertility, trace-metal transport, and the acid–base status of soils and natural waters. He is also involved in the interdisciplinary study of biogeochemical cycles at the Hubbard Brook Experimental Forest in the United States. He has research interests in the fate of trace metals (lead, zinc, copper, and nickel) in forest soils and landscapes; the effects of clear-cut logging on soils and drainage waters; and the changing acid–base chemistry of soils historically affected by acid rain. He served on the US Environmental Protection Agency's Clean Air Scientific Advisory Committee Lead Review Panel in 2011-2013, which established the National Ambient Air Quality Standard for lead. He has been an associate editor for the *Soil Science Society of America Journal* and the *Journal of Soils and Sediments*. Dr. Johnson has a BSE in civil and urban engineering, an MA in statistics, and a PhD in geology from the University of Pennsylvania.

Investigative Strategies for Lead-Source Attribution at Superfund Sites Associated with Mining Activities

William I. Manton is a professor of geology at the University of Texas at Dallas. His early work focused on the contribution of lead from gasoline to lead in blood. He continued working in the fields of toxicology and environmental medicine using stable-isotope dilution to measure concentrations of zinc in the brain and spinal cord and lead in blood serum and cerebrospinal fluid. He has used variations in lead-isotope ratios to determine how children acquire lead and exploited the long residence of lead in bone to study conditions, such as pregnancy, under which the skeleton might be resorbed. He has also been involved in studies in which animals have been dosed with stable lead isotopes, including investigations of lead poisoning from retained bullets and the mobilization of lead from the skeleton during pregnancy and after ovariectomy to stimulate menopause. He has also published on lead in the US diet and its unexpectedly high concentrations in cocoa and chocolate. He received his PhD in geochronology from the University of Witwatersrand, South Africa.

Jerry R. Miller is the Whitmire Professor of Environmental Science in the Department of Geosciences and Natural Resources at Western Carolina University. His research interests include assessment of the transport and fate of heavy metals in rivers and lakes, sediment geochemical fingerprinting with multivariate and isotopic methods, documentation of the effects of natural and anthropogenic disturbances on sediment yields and river processes, and restoration of riparian ecosystems. He received his PhD in geology from Southern Illinois University, Carbondale.

Peggy A. O'Day is professor of life and environmental sciences at the University of California, Merced. Dr. O'Day studies the chemistry, reaction, and transport of inorganic contaminants and species, primarily metal and metalloid elements, in surface and subsurface systems. She specializes in the use of spectroscopic and microscopic methods, especially synchrotron x-ray techniques, to determine element speciation and molecular-scale mechanisms of biogeochemical reactions in natural systems and laboratory analogues. She develops and applies thermodynamic, kinetic, and reactive transport models for synthesis and quantitative description of biogeochemical cycling, reactivity, transport, and bioavailability. She received a PhD in applied earth sciences from Stanford University.

John Toll is a partner at Windward Environmental LLC. He is recognized for his work in ecologic modeling, risk assessment, uncertainty analysis, and environmental decision analysis. He works primarily on complex contaminated sediment sites and leads teams that conduct remedial investigations and feasibility studies, ecologic risk assessments, and bioaccumulation modeling. He is the author or a co-author of numerous scientific papers on ecologic modeling and risk assessment and environmental decision analysis. Dr. Toll is a senior editor of the journal *Integrated Environmental Assessment and Management* and is a member of the board of directors of the Society of Environmental Toxicology and Chemistry (SETAC) North America. He earned his BS in chemical engineering from the University of Iowa and his PhD in engineering and public policy from Carnegie Mellon University.

Warren White is a researcher at the Crocker Nuclear Laboratory of the University of California, Davis. His research focuses on airborne particles and visibility impairment. He served on the review panel for the Air Quality Criteria for Particulate Matter Document and was a member of the US Environmental Protection Agency Clean Air Science Advisory Committee and its particulate-matter monitoring subcommittee. He has served on several National Research Council committees. He received his PhD in mathematics from the University of Wisconsin.

C

Open Session Meeting Agendas

COMMITTEE ON SOURCES OF LEAD CONTAMINATION AT OR NEAR SUPERFUND SITES

FIRST MEETING
Open Session: November 21, 2016
National Academies Keck Center, Room 100
500 Fifth Street, NW, Washington, DC 20001

PUBLIC AGENDA

1:00 **Purpose of Open Session and Introduction of Committee Members**
Edward Bouwer
Chair, Committee on Sources of Lead Contamination at or near Superfund Sites

1:15 **EPA Perspective on Study Objectives and Background**
Michele Burgess
Senior Biologist
Office of Land and Emergency Management
Office of Superfund Remediation and Technology Innovation
US Environmental Protection Agency

2:15 **Natural and Anthropogenic Sources of Lead in the Big River Watershed**
Teresa Bowers
President, Gradient
Michael Montgomery
Senior Attorney, The Doe Run Company

3:15 **Open Microphone – Opportunity for Public Comment**

4:00 ***End of Open Session***

SECOND MEETING
Open Sessions: January 18, 2017
Southeast Missouri Lead-Mining District

OPEN-SESSION AGENDA I: TOUR OF SOUTHEAST MISSOURI LEAD MINING DISTRICT

9:00 **Historical Perspective of Mining and Milling**
Art Hebrank, Site Administrator of Missouri Mines State Historic Site
Location: Missouri Mines State Historic Site, located southeast of the intersection of Highway 32 and Business 32/67 in Park Hills, MO

Copyright National Academy of Sciences. All rights reserved.

10:30 **Example of Residential Park Remediation**
Location: Haney Park, Located at the 500 Block of Crane Street (Near Intersection of Crane and Kelly Street), Park Hills, MO

11:00 **National Mine Tailings Site**
Location: Park Hills Industrial Park (near the intersection of Parkway Drive and S. Chamber Street), Park Hills, MO

11:45 ***Lunch Break***

1:00 **Mine Tailings Site Adjacent to Big River**
Location: Desloge Mine Tailings Site (Located between Landfill Road and W. Oak Street, Desloge, MO) and Bone Hole County Access Point (located off of Landfill Road, Desloge, MO)

2:00 **Example of State Park Remediation**
Bill Bonnell, Site Administrator
Location: St Joe State Park (located on Pimville Road about 2.4 miles southeast of the intersection of Highway 32 and Pimville Road from Park Hills, MO or about 4.25 miles northwest of the intersection of Bray Road and Pimville Road from Farmington, MO)

3:00 ***Tour Concludes***

OPEN-SESSION AGENDA II: PRESENTATIONS ON GEOLOGY AND MINING
Mineral Area College
North College Room, College Park
112 Dixie Kohn Drive, Park Hills, MO 63601

3:30 **Purpose of Open Session and Introduction of Committee Members**
Edward Bouwer
Chair, Committee on Sources of Lead Contamination at or near Superfund Sites

3:45 **Southeastern Missouri Geology and Mining in the Old and New Lead Belts**
Cheryl M. Seeger
Geologist
Missouri Geological Survey

4:30 **Mining, Milling, and Waste Handling Procedures at Active Lead-Mining Sites**
Mark Yingling
Vice President, Environmental, Health & Safety
Doe Run

5:15 ***Dinner Break***

OPEN-SESSION AGENDA III: PRESENTATIONS ON LEAD CONTAMINATION AND OPPORTUNITY FOR PUBLIC COMMENT
Mineral Area College
North College Room, College Park
112 Dixie Kohn Drive, Park Hills, MO 63601

6:45 **Purpose of Open Session and Introduction of Committee Members**
Edward Bouwer
Chair, Committee on Sources of Lead Contamination at or near Superfund Sites

7:00 **Environmental Transport and Deposition of Lead in Southeastern Missouri**
Emitt Witt
Hydrogeologist
US Geological Survey

Copyright National Academy of Sciences. All rights reserved.

7:45 **Lead Contamination Associated with Various Sources**
Valerie Wilder
Chief, Site Assessment Unit, Superfund Section, MO Department of Natural Resources Hazardous Waste Program
Jonathan D. Garoutte
Chief, Bureau of Environmental Epidemiology, Department of Health and Senior Services

8:30 **Open Microphone – Opportunity for Public Comment**
NOTE: Those who want to make a public comment must register by 8 p.m. Each speaker has a maximum time limit of 5 minutes. Speakers are invited to submit relevant written materials.

9:30 ***End of Open Session***

Heavy Metals Toxicity and the Environment

Paul B Tchounwou,* Clement G Yedjou, Anita K Patlolla, and Dwayne J Sutton

Abstract

Heavy metals are naturally occurring elements that have a high atomic weight and a density at least 5 times greater than that of water. Their multiple industrial, domestic, agricultural, medical and technological applications have led to their wide distribution in the environment; raising concerns over their potential effects on human health and the environment. Their toxicity depends on several factors including the dose, route of exposure, and chemical species, as well as the age, gender, genetics, and nutritional status of exposed individuals. Because of their high degree of toxicity, arsenic, cadmium, chromium, lead, and mercury rank among the priority metals that are of public health significance. These metallic elements are considered systemic toxicants that are known to induce multiple organ damage, even at lower levels of exposure. They are also classified as human carcinogens (known or probable) according to the U.S. Environmental Protection Agency, and the International Agency for Research on Cancer. This review provides an analysis of their environmental occurrence, production and use, potential for human exposure, and molecular mechanisms of toxicity, genotoxicity, and carcinogenicity.

Feedback

Keywords: Heavy metals, production and use, human exposure, toxicity, genotoxicity, carcinogenicity

Introduction

Heavy metals are defined as metallic elements that have a relatively high density compared to water [1]. With the assumption that heaviness and toxicity are inter-related, heavy metals also include metalloids, such as arsenic, that are able to induce toxicity at low level of exposure [2]. In recent years, there has been an increasing ecological and global public health concern associated with environmental contamination by these metals. Also, human exposure has risen dramatically as a result of an exponential increase of their use in several industrial, agricultural, domestic and technological applications [3]. Reported sources of heavy metals in the environment include geogenic, industrial, agricultural, pharmaceutical, domestic effluents, and atmospheric sources [4]. Environmental pollution is very prominent in point source areas such as mining, foundries and smelters, and other metal-based industrial operations [1, 3, 4].

Although heavy metals are naturally occurring elements that are found throughout the earth's crust, most environmental contamination and human exposure result from anthropogenic activities such as mining and smelting operations, industrial production and use, and domestic and agricultural use of metals and metal-containing compounds [4–7]. Environmental contamination can also occur through metal corrosion, atmospheric deposition, soil erosion of metal ions and leaching of heavy metals, sediment re-suspension and metal evaporation from water resources to soil and ground water [8]. Natural phenomena such as weathering and volcanic eruptions have also been reported to significantly contribute to heavy metal pollution [1, 3, 4, 7, 8]. Industrial sources include metal processing in refineries, coal burning in power plants, petroleum combustion, nuclear power stations and high tension lines, plastics, textiles, microelectronics, wood preservation and paper processing plants [9–11].

It has been reported that metals such as cobalt (Co), copper (Cu), chromium (Cr), iron (Fe), magnesium (Mg), manganese (Mn), molybdenum (Mo), nickel (Ni), selenium (Se) and zinc (Zn) are essential nutrients that are required for various biochemical and physiological functions [12]. Inadequate supply of these micro-nutrients results in a variety of deficiency diseases or syndromes [12].

Heavy metals are also considered as trace elements because of their presence in trace concentrations (ppb range to less than 10ppm) in various environmental matrices [13]. Their bioavailability is influenced by physical factors such as temperature, phase association, adsorption and sequestration. It is also affected by chemical factors that influence speciation at thermodynamic equilibrium, complexation kinetics, lipid solubility and octanol/water partition coefficients [14]. Biological factors such as species characteristics, trophic interactions, and biochemical/physiological adaptation, also play an important role [15].

The essential heavy metals exert biochemical and physiological functions in plants and animals. They are important constituents of several key enzymes and play important roles in various oxidation-reduction reactions [12]. Copper for example serves as an essential co-factor for several oxidative stress-related enzymes including catalase, superoxide dismutase, peroxidase, cytochrome c oxidases, ferroxidases, monoamine oxidase, and dopamine β-monooxygenase [16–18]. Hence, it is an essential nutrient that is incorporated into a number of metalloenzymes involved in hemoglobin formation, carbohydrate metabolism, catecholamine biosynthesis, and cross-linking of collagen, elastin, and hair keratin. The ability of copper to cycle between an oxidized state, Cu(II), and reduced state, Cu(I), is used by cuproenzymes involved in redox reactions [16–18]. However, it is this property of copper that also makes it potentially toxic because the transitions between Cu(II) and Cu(I) can result in the generation of superoxide and hydroxyl radicals [16–19]. Also, excessive exposure to copper has been linked to cellular damage leading to Wilson disease in humans [18, 19]. Similar to copper, several other essential elements are required for biologic functioning, however, an excess amount of such metals produces cellular and tissue damage leading to a variety of adverse effects and human diseases. For some including chromium and copper, there is a very narrow range of concentrations between beneficial and toxic effects [19, 20]. Other metals such as aluminium (Al), antinomy (Sb), arsenic (As), barium (Ba), beryllium (Be), bismuth (Bi), cadmium (Cd), gallium (Ga), germanium (Ge), gold (Au), indium (In), lead (Pb), lithium (Li), mercury (Hg), nickel (Ni), platinum (Pt), silver (Ag), strontium (Sr), tellurium (Te), thallium (Tl), tin (Sn), titanium (Ti), vanadium (V) and uranium (U) have no established biological functions and are considered as non-essential metals [20].

In biological systems, heavy metals have been reported to affect cellular organelles and components such as cell membrane, mitochondrial, lysosome, endoplasmic reticulum, nuclei, and some enzymes involved in metabolism, detoxification, and damage repair [21]. Metal ions have been found to interact with cell components such as DNA and nuclear proteins, causing DNA damage and conformational changes that may lead to cell cycle modulation, carcinogenesis or apoptosis [20–22]. Several studies from our laboratory have demonstrated that reactive oxygen species (ROS) production and oxidative stress play a key role in the toxicity and carcinogenicity of metals such as arsenic [23, 24, 25], cadmium [26], chromium [27, 28], lead [29, 30], and mercury [31, 32]. Because of their high degree of toxicity, these five elements rank among the priority metals that are of great public health significance. They are all systemic toxicants that are known to induce multiple organ damage, even at lower levels of exposure. According to the United States Environmental Protection Agency (U.S. EPA), and the International Agency for Research on Cancer (IARC), these metals are also classified as either “known” or “probable” human carcinogens based on epidemiological and experimental studies showing an association between exposure and cancer incidence in humans and animals.

Heavy metal-induced toxicity and carcinogenicity involves many mechanistic aspects, some of which are not clearly elucidated or understood. However, each metal is known to have unique features and physic-chemical properties that confer to its specific toxicological mechanisms of action. This review provides an analysis of the environmental occurrence, production and use, potential for human exposure, and molecular mechanisms of toxicity, genotoxicity, and carcinogenicity of arsenic, cadmium, chromium, lead, and mercury.

Arsenic

Environmental Occurrence, Industrial Production and Use

Arsenic is a ubiquitous element that is detected at low concentrations in virtually all environmental matrices [33]. The major inorganic forms of arsenic include the trivalent arsenite and the pentavalent arsenate. The organic forms are the methylated metabolites – monomethylarsonic acid (MMA), dimethylarsinic acid (DMA) and trimethylarsine oxide. Environmental pollution by arsenic occurs as a result of natural phenomena such as volcanic eruptions and soil erosion, and anthropogenic activities [33]. Several arsenic-containing compounds are produced industrially, and have been used to manufacture products with agricultural applications such as insecticides, herbicides, fungicides, algicides, sheep dips, wood preservatives, and dye-stuffs. They have also been used in veterinary medicine for the eradication of tapeworms in sheep and cattle [34]. Arsenic compounds have also been used in the medical field for at least a century in the treatment of syphilis, yaws, amoebic dysentery, and trypanosomaiasis [34,35]. Arsenic-based drugs are still used in treating certain tropical diseases such as African sleeping sickness and amoebic dysentery, and in veterinary medicine to treat parasitic diseases, including filariasis in dogs and black head in turkeys and chickens [35]. Recently, arsenic trioxide has been approved by the Food and Drug Administration as an anticancer agent in the treatment of acute promeylocytic leukemia [36]. Its therapeutic action has been attributed to the induction of programmed cell death (apoptosis) in leukemia cells [24].

Potential for Human Exposure

It is estimated that several million people are exposed to arsenic chronically throughout the world, especially in countries like Bangladesh, India, Chile, Uruguay, Mexico, Taiwan, where the ground water is contaminated with high concentrations of arsenic. Exposure to arsenic occurs via the oral route (ingestion), inhalation, dermal contact, and the parenteral route to some extent [33,34,37]. Arsenic concentrations in air range from 1 to 3 ng/m^3 in remote locations (away from human releases), and from 20 to 100 ng/m^3 in cities. Its water concentration is usually less than 10μg/L, although higher levels can occur near natural mineral deposits or mining sites. Its concentration in various foods ranges from 20 to 140 ng/kg [38]. Natural levels of arsenic in soil usually range from 1 to 40 mg/kg, but pesticide application or waste disposal can produce much higher values [25].

Diet, for most individuals, is the largest source of exposure, with an average intake of about 50 μg per day. Intake from air, water and soil are usually much smaller, but exposure from these media may become significant in areas of arsenic contamination. Workers who produce or use arsenic compounds in such occupations as vineyards, ceramics, glass-making, smelting, refining of metallic ores, pesticide manufacturing and application, wood preservation, semiconductor manufacturing can be exposed to substantially higher

levels of arsenic [39]. Arsenic has also been identified at 781 sites of the 1,300 hazardous waste sites that have been proposed by the U.S. EPA for inclusion on the national priority list [33,39]. Human exposure at these sites may occur by a variety of pathways, including inhalation of dusts in air, ingestion of contaminated water or soil, or through the food chain [40].

Contamination with high levels of arsenic is of concern because arsenic can cause a number of human health effects. Several epidemiological studies have reported a strong association between arsenic exposure and increased risks of both carcinogenic and systemic health effects [41]. Interest in the toxicity of arsenic has been heightened by recent reports of large populations in West Bengal, Bangladesh, Thailand, Inner Mongolia, Taiwan, China, Mexico, Argentina, Chile, Finland and Hungary that have been exposed to high concentrations of arsenic in their drinking water and are displaying various clinico-pathological conditions including cardiovascular and peripheral vascular disease, developmental anomalies, neurologic and neurobehavioural disorders, diabetes, hearing loss, portal fibrosis, hematologic disorders (anemia, leukopenia and eosinophilia) and carcinoma [25, 33, 35, 39]. Arsenic exposure affects virtually all organ systems including the cardiovascular, dermatologic, nervous, hepatobilliary, renal, gastro-intestinal, and respiratory systems [41]. Research has also pointed to significantly higher standardized mortality rates for cancers of the bladder, kidney, skin, and liver in many areas of arsenic pollution. The severity of adverse health effects is related to the chemical form of arsenic, and is also time- and dose-dependent [42,43]. Although the evidence of carcinogenicity of arsenic in humans seems strong, the mechanism by which it produces tumors in humans is not completely understood [44].

Mechanisms of Toxicity and Carcinogenicity

Analyzing the toxic effects of arsenic is complicated because the toxicity is highly influenced by its oxidation state and solubility, as well as many other intrinsic and extrinsic factors [45]. Several studies have indicated that the toxicity of arsenic depends on the exposure dose, frequency and duration, the biological species, age, and gender, as well as on individual susceptibilities, genetic and nutritional factors [46]. Most cases of human toxicity from arsenic have been associated with exposure to inorganic arsenic. Inorganic trivalent arsenite (As^{III}) is 2–10 times more toxic than pentavalent arsenate (As^{V}) [5]. By binding to thiol or sulfhydryl groups on proteins, As (III) can inactivate over 200 enzymes. This is the likely mechanism responsible for arsenic's widespread effects on different organ systems. As (V) can replace phosphate, which is involved in many biochemical pathways [5, 47].

One of the mechanisms by which arsenic exerts its toxic effect is through impairment of cellular respiration by the inhibition of various mitochondrial enzymes, and the uncoupling of oxidative phosphorylation. Most toxicity of arsenic results from its ability to interact with sulfhydryl groups of proteins and enzymes, and to substitute phosphorous in a variety of biochemical reactions [48]. Arsenic *in vitro* reacts with protein sulfhydryl groups to inactivate enzymes, such as dihydrolipoyl dehydrogenase and thiolase, thereby producing inhibited oxidation of pyruvate and betaoxidation of fatty acids [49]. The major metabolic pathway for inorganic arsenic in humans is methylation. Arsenic trioxide is methylated to two major metabolites via a non-enzymatic process to monomethylarsonic

acid (MMA), which is further methylated enzymatically to dimethyl arsenic acid (DMA) before excretion in the urine [40, 47]. It was previously thought that this methylation process is a pathway of arsenic detoxification, however, recent studies have pointed out that some methylated metabolites may be more toxic than arsenite if they contain trivalent forms of arsenic [41].

Tests for genotoxicity have indicated that arsenic compounds inhibit DNA repair, and induce chromosomal aberrations, sister-chromatid exchanges, and micronuclei formation in both human and rodent cells in culture [50–52] and in cells of exposed humans [53]. Reversion assays with *Salmonella typhimurium* fail to detect mutations that are induced by arsenic compounds. Although arsenic compounds are generally perceived as weak mutagens in bacterial and animal cells, they exhibit clastogenic properties in many cell types *in vivo* and *in vitro* [54]. In the absence of animal models, *in vitro* cell transformation studies become a useful means of obtaining information on the carcinogenic mechanisms of arsenic toxicity. Arsenic and arsenical compounds are cytotoxic and induce morphological transformations of Syrian hamster embryo (SHE) cells as well as mouse C3H10T1/2 cells and BALB/3T3 cells [55, 56].

Based on the comet assay, it has been reported that arsenic trioxide induces DNA damage in human lymphophytes [57] and also in mice leukocytes [58]. Arsenic compounds have also been shown to induce gene amplification, arrest cells in mitosis, inhibit DNA repair, and induce expression of the *c-fos* gene and the oxidative stress protein heme oxygenase in mammalian cells [58, 59]. They have been implicated as promoters and comutagens for a variety of toxic agents [60]. Recent studies in our laboratory have demonstrated that arsenic trioxide is cytotoxic and able to transcriptionally induce a significant number of stress genes and related proteins in human liver carcinoma cells [61].

Epidemiological investigations have indicated that long-term arsenic exposure results in promotion of carcinogenesis. Several hypotheses have been proposed to describe the mechanism of arsenic-induced carcinogenesis. Zhao et al. [62] reported that arsenic may act as a carcinogen by inducing DNA hypomethylation, which in turn facilitates aberrant gene expression. Additionally, it was found that arsenic is a potent stimulator of extracellular signal-regulated protein kinase Erk1 and AP-1 transactivational activity, and an efficient inducer of *c-fos* and *c-jun* gene expression [63]. Induction of *c-jun* and *c-fos* by arsenic is associated with activation of JNK [64]. However, the role of JNK activation by arsenite in cell transformation or tumor promotion is unclear.

In another study, Trouba et al. [65] concluded that long-term exposure to high levels of arsenic might make cells more susceptible to mitogenic stimulation and that alterations in mitogenic signaling proteins might contribute to the carcinogenic action of arsenic. Collectively, several recent studies have demonstrated that arsenic can interfere with cell signaling pathways (e.g., the p53 signaling pathway) that are frequently implicated in the promotion and progression of a variety of tumor types in experimental animal models, and of some human tumors [66, 68]. However, the specific alterations in signal transduction pathways or the actual targets that contribute to the development of arsenic-induced tumors in humans following chronic consumption of arsenic remains uncertain.

Recent clinical trials have found that arsenic trioxide has therapeutic value in the treatment of acute promyelocytic leukemia, and there is interest in exploring its effectiveness in the treatment of a variety of other cancers [69,70]. In acute promyelocytic leukemia, the specific molecular event critical to the formation of malignant cells is known. A study by Puccetti et al. [71] found that forced overexpression of BCR-ABL susceptibility in human lymphoblasts cells resulted in greatly enhanced sensitivity to arsenic-induced apoptosis. They also concluded that arsenic trioxide is a tumor specific agent capable of inducing apoptosis selectively in acute promyelocytic leukemia cells. Several recent studies have shown that arsenic can induce apoptosis through alterations in other cell signaling pathways [72,73]. In addition to acute peomyelocytic leukemia, arsenic is thought to have therapeutic potential for myeloma [74]. In summary, numerous cancer chemotherapy studies in cell cultures and in patients with acute promyelocytic leukemia demonstrate that arsenic trioxide administration can lead to cell-cycle arrest and apoptosis in malignant cells.

Previous studies have also examined p53 gene expression and mutation in tumors obtained from subjects with a history of arsenic ingestion. p53 participates in many cellular functions, cell-cycle control, DNA repair, differentiation, genomic plasticity and programmed cell death. Additional support for the hypothesis that arsenic can modulate gene expression has been provided by several different studies [75,76]. Collectively, these studies provide further evidence that various forms of arsenic can alter gene expression and that such changes could contribute substantially to the toxic and carcinogenic actions of arsenic treatment in human populations [77].

Several *in vitro* studies in our laboratory have demonstrated that arsenic modulates DNA synthesis, gene and protein expression, genotoxicity, mitosis and/or apoptotic mechanisms in various cell lines including keratinocytes, melanocytes, dendritic cells, dermal fibroblasts, microvascular endothelial cells, monocytes, and T-cells [78], colon cancer cells [79], lung cancer cells [80], human leukemia cells [81], Jurkat-T lymphocytes [82], and human liver carcinoma cells [83]. We have also shown that oxidative stress plays a key role in arsenic induced cytotoxicity, a process that is modulated by pro- and/or anti-oxidants such as ascorbic acid and n-acetyl cysteine [84–86]. We have further demonstrated that the toxicity of arsenic depends on its chemical form, the inorganic form being more toxic than the organic one [42].

Various hypotheses have been proposed to explain the carcinogenicity of inorganic arsenic. Nevertheless, the molecular mechanisms by which this arsenical induces cancer are still poorly understood. Results of previous studies have indicated that inorganic arsenic does not act through classic genotoxic and mutagenic mechanisms, but rather may be a tumor promoter that modifies signal transduction pathways involved in cell growth and proliferation [68]. Although much progress has been recently made in the area of arsenic's possible mode(s) of carcinogenic action, a scientific consensus has not yet reached. A recent review discusses nine different possible modes of action of arsenic carcinogenesis: induced chromosomal abnormalities, oxidative stress, altered DNA repair, altered DNA methylation patterns, altered growth factors, enhanced cell proliferation, promotion/progression, suppression of p53, and gene amplification [87]. Presently, three modes (chromosomal abnormality, oxidative stress, and altered growth factors) of arsenic carcinogenesis have shown a degree of positive evidence, both in experimental systems (animal and human cells) and in human tissues.

The remaining possible modes of carcinogenic action (progression of carcinogenesis, altered DNA repair, p53 suppression, altered DNA methylation patterns and gene amplification) do not have as much evidence, particularly from *in vivo* studies with laboratory animals, *in vitro* studies with cultured human cells, or human data from case or population studies. Thus, the mode-of-action studies suggest that arsenic might be acting as a cocarcinogen, a promoter, or a progressor of carcinogenesis.

Cadmium

Environmental Occurrence, Industrial Production and Use

Cadmium is a heavy metal of considerable environmental and occupational concern. It is widely distributed in the earth's crust at an average concentration of about 0.1 mg/kg. The highest level of cadmium compounds in the environment is accumulated in sedimentary rocks, and marine phosphates contain about 15 mg cadmium/kg [88].

Cadmium is frequently used in various industrial activities. The major industrial applications of cadmium include the production of alloys, pigments, and batteries [89]. Although the use of cadmium in batteries has shown considerable growth in recent years, its commercial use has declined in developed countries in response to environmental concerns. In the United States for example, the daily cadmium intake is about 0.4μg/kg/day, less than half of the U.S. EPA's oral reference dose [90]. This decline has been linked to the introduction of stringent effluent limits from plating works and, more recently, to the introduction of general restrictions on cadmium consumption in certain countries.

Potential for Human Exposure

The main routes of exposure to cadmium are via inhalation or cigarette smoke, and ingestion of food. Skin absorption is rare. Human exposure to cadmium is possible through a number of several sources including employment in primary metal industries, eating contaminated food, smoking cigarettes, and working in cadmium-contaminated work places, with smoking being a major contributor [91, 92]. Other sources of cadmium include emissions from industrial activities, including mining, smelting, and manufacturing of batteries, pigments, stabilizers, and alloys [93]. Cadmium is also present in trace amounts in certain foods such as leafy vegetables, potatoes, grains and seeds, liver and kidney, and crustaceans and mollusks [94]. In addition, foodstuffs that are rich in cadmium can greatly increase the cadmium concentration in human bodies. Examples are liver, mushrooms, shellfish, mussels, cocoa powder and dried seaweed. An important distribution route is the circulatory system whereas blood vessels are considered to be main stream organs of cadmium toxicity. Chronic inhalation exposure to cadmium particulates is generally associated with changes in pulmonary

function and chest radiographs that are consistent with emphysema [95]. Workplace exposure to airborne cadmium particulates has been associated with decreases in olfactory function [96]. Several epidemiologic studies have documented an association of chronic low-level cadmium exposure with decreases in bone mineral density and osteoporosis [97–99].

Exposure to cadmium is commonly determined by measuring cadmium levels in blood or urine. Blood cadmium reflects recent cadmium exposure (from smoking, for example). Cadmium in urine (usually adjusted for dilution by calculating the cadmium/creatinine ratio) indicates accumulation, or kidney burden of cadmium [100, 101]. It is estimated that about 2.3% of the U.S. population has elevated levels of urine cadmium (>2μg/g creatinine), a marker of chronic exposure and body burden [102]. Blood and urine cadmium levels are typically higher in cigarette smokers, intermediate in former smokers and lower in nonsmokers [102, 103]. Because of continuing use of cadmium in industrial applications, the environmental contamination and human exposure to cadmium have dramatically increased during the past century [104].

Molecular Mechanisms of Toxicity and Carcinogenicity

Cadmium is a severe pulmonary and gastrointestinal irritant, which can be fatal if inhaled or ingested. After acute ingestion, symptoms such as abdominal pain, burning sensation, nausea, vomiting, salivation, muscle cramps, vertigo, shock, loss of consciousness and convulsions usually appear within 15 to 30 min [105]. Acute cadmium ingestion can also cause gastrointestinal tract erosion, pulmonary, hepatic or renal injury and coma, depending on the route of poisoning [105, 106]. Chronic exposure to cadmium has a depressive effect on levels of norepinephrine, serotonin, and acetylcholine [107]. Rodent studies have shown that chronic inhalation of cadmium causes pulmonary adenocarcinomas [108, 109]. It can also cause prostatic proliferative lesions including adenocarcinomas, after systemic or direct exposure [110].

Although the mechanisms of cadmium toxicity are poorly understood, it has been speculated that cadmium causes damage to cells primarily through the generation of ROS [111], which causes single-strand DNA damage and disrupts the synthesis of nucleic acids and proteins [112]. Studies using two-dimensional gel electrophoresis have shown that several stress response systems are expressed in response to cadmium exposure, including those for heat shock, oxidative stress, stringent response, cold shock, and SOS [113– 115]. *In vitro* studies indicate that cadmium induces cytotoxic effects at the concentrations 0.1 to 10 mM and free radical-dependent DNA damage [116, 117]. *In vivo* studies have shown that cadmium modulates male reproduction in mice model at a concentration of 1 mg/kg body weight [118]. However, cadmium is a weak mutagen when compared with other carcinogenic metals [119]. Previous reports have indicated that cadmium affects signal transduction pathways; inducing inositol polyphosphate formation, increasing cytosolic free calcium levels in various cell types [120], and blocking calcium channels [121, 122]. At lower concentrations (1–100 μM), cadmium binds to proteins, decreases DNA repair [123], activates protein degradation, up-regulates cytokines and proto-oncogenes such as c-*fos*, c-*jun*, and c-*myc* [124], and induces expression of several genes including metallothioneins [125], heme oxygenases, glutathione transferases, heat-shock proteins, acute-phase reactants, and DNA polymerase β [126].

Cadmium compounds are classified as human carcinogens by several regulatory agencies. The International Agency for Research on Cancer [91] and the U.S. National Toxicology Program have concluded that there is adequate evidence that cadmium is a human carcinogen. This designation as a human carcinogen is based primarily on repeated findings of an association between occupational cadmium exposure and lung cancer, as well as on very strong rodent data showing the pulmonary system as a target site [91]. Thus, the lung is the most definitively established site of human carcinogenesis from cadmium exposure. Other target tissues of cadmium carcinogenesis in animals include injection sites, adrenals, testes, and the hemopoietic system [91, 108, 109]. In some studies, occupational or environmental cadmium exposure has also been associated with development of cancers of the prostate, kidney, liver, hematopoietic system and stomach [108, 109]. Carcinogenic metals including arsenic, cadmium, chromium, and nickel have all been associated with DNA damage through base pair mutation, deletion, or oxygen radical attack on DNA [126]. Animal studies have demonstrated reproductive and teratogenic effects. Small epidemiologic studies have noted an inverse relationship between cadmium in cord blood, maternal blood or maternal urine and birth weight and length at birth [127, 128].

Chromium

Environmental Occurrence, Industrial Production and Use

Chromium (Cr) is a naturally occurring element present in the earth's crust, with oxidation states (or valence states) ranging from chromium (II) to chromium (VI) [129]. Chromium compounds are stable in the trivalent [Cr(III)] form and occur in nature in this state in ores, such as ferrochromite. The hexavalent [Cr(VI)] form is the second-most stable state [28]. Elemental chromium [Cr(0)] does not occur naturally. Chromium enters into various environmental matrices (air, water, and soil) from a wide variety of natural and anthropogenic sources with the largest release coming from industrial establishments. Industries with the largest contribution to chromium release include metal processing, tannery facilities, chromate production, stainless steel welding, and ferrochrome and chrome pigment production. The increase in the environmental concentrations of chromium has been linked to air and wastewater release of chromium, mainly from metallurgical, refractory, and chemical industries. Chromium released into the environment from anthropogenic activity occurs mainly in the hexavalent form [Cr(VI)] [130]. Hexavalent chromium [Cr(VI)] is a toxic industrial pollutant that is classified as human carcinogen by several regulatory and non-regulatory agencies [130–132]. The health hazard associated with exposure to chromium depends on its oxidation state, ranging from the low toxicity of the metal form to the high toxicity of the hexavalent form. All Cr(VI)-containing compounds were once thought to be man-made, with only Cr(III) naturally ubiquitous in air, water, soil and biological materials. Recently, however, naturally occurring Cr(VI) has been found in ground and surface waters at values exceeding the World Health Organization limit for drinking water of 50 μg of Cr(VI) per liter [133]. Chromium is widely used in numerous industrial processes and as a result, is a contaminant of many environmental systems [134]. Commercially chromium compounds are used in industrial welding, chrome plating, dyes and pigments, leather tanning and wood preservation. Chromium is also used as anticorrosive in cooking systems and boilers [135, 136].

Potential for Human Exposure

It is estimated that more than 300,000 workers are exposed annually to chromium and chromium-containing compounds in the workplace. In humans and animals, [Cr(III)] is an essential nutrient that plays a role in glucose, fat and protein metabolism by potentiating the action of insulin [5]. However, occupational exposure has been a major concern because of the high risk of Cr-induced diseases in industrial workers occupationally exposed to Cr(VI) [137]. Also, the general human population and some wildlife may also be at risk. It is estimated that 33 tons of total Cr are released annually into the environment [130]. The U.S. Occupational Safety and Health Administration (OSHA) recently set a "safe" level of 5μg/m^3, for an 8-hr time-weighted average, even though this revised level may still pose a carcinogenic risk [138]. For the general human population, atmospheric levels range from 1 to 100 ng/cm^3 [139], but can exceed this range in areas that are close to Cr manufacturing.

Non-occupational exposure occurs via ingestion of chromium containing food and water whereas occupational exposure occurs via inhalation [140]. Chromium concentrations range between 1 and 3000 mg/kg in soil, 5 to 800 μg/L in sea water, and 26 μg/L to 5.2 mg/L in rivers and lakes [129]. Chromium content in foods varies greatly and depends on the processing and preparation. In general, most fresh foods typically contain chromium levels ranging from <10 to 1,300 μg/kg. Present day workers in chromium-related industries can be exposed to chromium concentrations two orders of magnitude higher than the general population [141]. Even though the principal route of human exposure to chromium is through inhalation, and the lung is the primary target organ, significant human exposure to chromium has also been reported to take place through the skin [142, 143]. For example, the widespread incidence of dermatitis noticed among construction workers is attributed to their exposure to chromium present in cement [143]. Occupational and environmental exposure to Cr(VI)-containing compounds is known to cause multiorgan toxicity such as renal damage, allergy and asthma, and cancer of the respiratory tract in humans [5, 144].

Breathing high levels of chromium (VI) can cause irritation to the lining of the nose, and nose ulcers. The main health problems seen in animals following ingestion of chromium (VI) compounds are irritation and ulcers in the stomach and small intestine, anemia, sperm damage and male reproductive system damage. Chromium (III) compounds are much less toxic and do not appear to cause these problems. Some individuals are extremely sensitive to chromium(VI) or chromium(III), allergic reactions consisting of severe redness and swelling of the skin have been noted. An increase in stomach tumors was observed in humans and animals exposed to chromium(VI) in drinking water. Accidental or intentional ingestion of extremely high doses of chromium (VI) compounds by humans has resulted in severe respiratory, cardiovascular, gastrointestinal, hematological, hepatic, renal, and neurological effects as part of the sequelae leading to death or in patients who survived because of medical treatment [141]. Although the evidence of carcinogenicity of chromium in humans and terrestrial mammals seems strong, the mechanism by which it causes cancer is not completely understood [145].

Mechanisms of Toxicity and Carcinogenicity

Major factors governing the toxicity of chromium compounds are oxidation state and solubility. Cr(VI) compounds, which are powerful oxidizing agents and thus tend to be irritating and corrosive, appear to be much more toxic systemically than Cr(III) compounds, given similar amount and solubility [146, 147]. Although the mechanisms of biological interaction are uncertain, the variation in toxicity may be related to the ease with which Cr(VI) can pass through cell membranes and its subsequent intracellular reduction to reactive intermediates. Since Cr(III) is poorly absorbed by any route, the toxicity of chromium is mainly attributable to the Cr(VI) form. It can be absorbed by the lung and gastrointestinal tract, and even to a certain extent by intact skin. The reduction of Cr(VI) is considered as being a detoxification process when it occurs at a distance from the target site for toxic or genotoxic effect while reduction of Cr(VI) may serve to activate chromium toxicity if it takes place in or near the cell nucleus of target organs [148]. If Cr(VI) is reduced to Cr(III) extracellularly, this form of the metal is not readily transported into cells and so toxicity is not observed. The balance that exists between extracellular Cr(VI) and intracellular Cr(III) is what ultimately dictates the amount and rate at which Cr(VI) can enter cells and impart its toxic effects [134].

Cr(VI) enters many types of cells and under physiological conditions can be reduced by hydrogen peroxide (H_2O_2), glutathione (GSH) reductase, ascorbic acid, and GSH to produce reactive intermediates, including Cr(V), Cr(IV), thiylradicals, hydroxyl radicals, and ultimately, Cr(III). Any of these species could attack DNA, proteins, and membrane lipids, thereby disrupting cellular integrity and functions [149, 150].

Studies with animal models have also reported many harmful effects of Cr (VI) on mammals. Subcutaneous administration of Cr (VI) to rats caused severe progressive proteinuria, urea nitrogen and creatinine, as well as elevation in serum alanine aminotransferase activity and hepatic lipid peroxide formation [151]. Similar studies reported by Gumbleton and Nicholls [152] found that Cr (VI) induced renal damage in rats when administered by single sub-cutaneous injections. Bagchi et al. demonstrated that rats received Cr (VI) orally in water induced hepatic mitochondrial and microsomal lipid peroxidation, as well as enhanced excretion of urinary lipid metabolites including malondialdehyde [153, 154].

Adverse health effects induced by Cr (VI) have also been reported in humans. Epidemiological investigations have reported respiratory cancers in workers occupationally exposed to Cr (VI)-containing compounds [142, 148]. DNA strand breaks in peripheral lymphocytes and lipid peroxidation products in urine observed in chromium-exposed workers also support the evidence of Cr (VI)-induced toxicity to humans [155, 156]. Oxidative damage is considered to be the underlying cause of these genotoxic effects including chromosomal abnormalities [157, 158], and DNA strand breaks [159]. Nevertheless, recent studies indicate a biological relevance of non-oxidative mechanisms in Cr(VI) carcinogenesis [160].

Carcinogenicity appears to be associated with the inhalation of the less soluble/insoluble Cr(VI) compounds. The toxicology of Cr(VI) does not reside with the elemental form. It varies greatly among a wide variety of very different Cr(VI) compounds [161]. Epidemiological evidence strongly points to Cr(VI) as the agent in carcinogenesis. Solubility and other characteristics of chromium, such as size, crystal modification, surface charge, and the ability to be phagocytized might be important in determining cancer risk [135].

Studies in our laboratory have indicated that chromium (VI) is cytotoxic and able to induce DNA damaging effects such as chromosomal abnormalities [162], DNA strand breaks, DNA fragmentation and oxidative stress in Sprague-Dawley rats and human liver carcinoma cells [27, 28]. Recently, our laboratory has also demonstrated that chromium (VI) induces biochemical, genotoxic and histopathologic effects in liver and kidney of goldfish, *carassius auratus* [163].

Various hypotheses have been proposed to explain the carcinogenicity of chromium and its salts, however some inherent difficulties exist when discussing metal carcinogenesis. A metal cannot be classified as carcinogenic per se since its different compounds may have different potencies. Because of the multiple chemical exposure in industrial establishments, it is difficult from an epidemiological standpoint to relate the carcinogenic effect to a single compound. Thus, the carcinogenic risk must often be related to a process or to a group of metal compounds rather than to a single substance. Differences in carcinogenic potential are related not only to different chemical forms of the same metal but also to the particle size of the inhaled aerosol and to physical characteristics of the particle such as surface charge and crystal modification [164].

Lead

Environmental Occurrence, Industrial Production and Use

Lead is a naturally occurring bluish-gray metal present in small amounts in the earth's crust. Although lead occurs naturally in the environment, anthropogenic activities such as fossil fuels burning, mining, and manufacturing contribute to the release of high concentrations. Lead has many different industrial, agricultural and domestic applications. It is currently used in the production of lead-acid batteries, ammunitions, metal products (solder and pipes), and devices to shield X-rays. An estimated 1.52 million metric tons of lead were used for various industrial applications in the United Stated in 2004. Of that amount, lead-acid batteries production accounted for 83 percent, and the remaining usage covered a range of products such as ammunitions (3.5 percent), oxides for paint, glass, pigments and chemicals (2.6 percent), and sheet lead (1.7 percent) [165, 166].

In recent years, the industrial use of lead has been significantly reduced from paints and ceramic products, caulking, and pipe solder [167]. Despite this progress, it has been reported that among 16.4 million United States homes with more than one child younger than 6 years per household, 25% of homes still had significant amounts of lead-contaminated deteriorated paint, dust, or adjacent bare soil [168]. Lead in dust and soil often re-contaminates cleaned houses [169] and contributes to elevating blood lead concentrations in children who play on bare, contaminated soil [170]. Today, the largest source of lead poisoning in children comes from dust and chips from deteriorating lead paint on interior surfaces [171]. Children who live in homes with deteriorating lead paint can achieve blood lead concentrations of 20μg/dL or greater [172].

Potential for Human Exposure

Exposure to lead occurs mainly via inhalation of lead-contaminated dust particles or aerosols, and ingestion of lead-contaminated food, water, and paints [173, 174]. Adults absorb 35 to 50% of lead through drinking water and the absorption rate for children may be greater than 50%. Lead absorption is influenced by factors such as age and physiological status. In the human body, the greatest percentage of lead is taken into the kidney, followed by the liver and the other soft tissues such as heart and brain, however, the lead in the skeleton represents the major body fraction [175]. The nervous system is the most vulnerable target of lead poisoning. Headache, poor attention spam, irritability, loss of memory and dullness are the early symptoms of the effects of lead exposure on the central nervous system [170, 173].

Since the late 1970's, lead exposure has decreased significantly as a result of multiple efforts including the elimination of lead in gasoline, and the reduction of lead levels in residential paints, food and drink cans, and plumbing systems [173, 174]. Several federal programs implemented by state and local health governments have not only focused on banning lead in gasoline, paint and soldered cans, but have also supported screening programs for lead poisoning in children and lead abatement in housing [167]. Despite the progress in these programs, human exposure to lead remains a serious health problem [176, 177]. Lead is the most systemic toxicant that affects several organs in the body including the kidneys, liver, central nervous system, hematopoetic system, endocrine system, and reproductive system [173].

Lead exposure usually results from lead in deteriorating household paints, lead in the work place, lead in crystals and ceramic containers that leaches into water and food, lead use in hobbies, and lead use in some traditional medicines and cosmetics [167, 174]. Several studies conducted by the National Health and Nutrition Examination surveys (NHANES) have measured blood lead levels in the U.S. populations and have assessed the magnitude of lead exposure by age, gender, race, income and degree of urbanization [176]. Although the results of these surveys have demonstrated a general decline in blood lead levels since the 1970s, they have also shown that large populations of children continue to have elevated blood lead levels (> 10μg/dL). Hence, lead poisoning remains one of the most common pediatric health problems in the United States today [167, 173, 174, 176–179]. Exposure to lead is of special

concern among women particularly during pregnancy. Lead absorbed by the pregnant mother is readily transferred to the developing fetus [180]. Human evidence corroborates animal findings [181], linking prenatal exposure to lead with reduced birth weight and preterm delivery [182], and with neuro-developmental abnormalities in offspring [183].

Molecular Mechanisms of Toxicity and Carcinogenicity

There are many published studies that have documented the adverse effects of lead in children and the adult population. In children, these studies have shown an association between blood level poisoning and diminished intelligence, lower intelligence quotient-IQ, delayed or impaired neurobehavioral development, decreased hearing acuity, speech and language handicaps, growth retardation, poor attention span, and anti social and diligent behaviors [178, 179, 184, 185]. In the adult population, reproductive effects, such as decreased sperm count in men and spontaneous abortions in women have been associated with high lead exposure [186, 187]. Acute exposure to lead induces brain damage, kidney damage, and gastrointestinal diseases, while chronic exposure may cause adverse effects on the blood, central nervous system, blood pressure, kidneys, and vitamin D metabolism [173, 174, 178, 179, 184–187].

One of the major mechanisms by which lead exerts its toxic effect is through biochemical processes that include lead's ability to inhibit or mimic the actions of calcium and to interact with proteins [173]. Within the skeleton, lead is incorporated into the mineral in place of calcium. Lead binds to biological molecules and thereby interfering with their function by a number of mechanisms. Lead binds to sulfhydryl and amide groups of enzymes, altering their configuration and diminishing their activities. Lead may also compete with essential metallic cations for binding sites, inhibiting enzyme activity, or altering the transport of essential cations such as calcium [188]. Many investigators have demonstrated that lead intoxication induces a cellular damage mediated by the formation of reactive oxygen species (ROS) [189]. In addition, Jiun and Hseien [190] demonstrated that the levels of malondialdehyde (MDA) in blood strongly correlate with lead concentration in the blood of exposed workers. Other studies showed that the activities of antioxidant enzymes, including superoxide dismutase (SOD), and glutathione peroxidase in erythrocytes of workers exposed to lead are remarkably higher than that in non-exposed workers [191]. A series of recent studies in our laboratory demonstrated that lead-induced toxicity and apoptosis in human cancer cells involved several cellular and molecular processes including induction of cell death and oxidative stress [29, 192], transcriptional activation of stress genes [30], DNA damage [29], externalization of phosphatidylserine and activation of caspase-3 [193].

A large body of research has indicated that lead acts by interfering with calcium-dependent processes related to neuronal signaling and intracellular signal transduction. Lead perturbs intracellular calcium cycling, altering releasability of organelle stores, such as endoplasmic reticulum and mitochondria [194, 195]. In some cases lead inhibits calcium-dependent events, including calcium-dependent release of several neurotransmitters and receptor-coupled ionophores in glutamatergic neurons [196]. In other cases lead appears to augment calcium-dependent events, such as protein kinase C and calmodulin [194, 197].

Experimental studies have indicated that lead is potentially carcinogenic, inducing renal tumors in rats and mice [198, 199], and is therefore considered by the IARC as a probable human carcinogen [200]. Lead exposure is also known to induce gene mutations and sister chromatid exchanges [201, 202], morphological transformations in cultured rodent cells [203], and to enhance anchorage independence in diploid human fibroblasts [204]. *In vitro* and *in vivo* studies indicated that lead compounds cause genetic damage through various indirect mechanisms that include inhibition of DNA synthesis and repair, oxidative damage, and interaction with DNA-binding proteins and tumor suppressor proteins. Studies by Roy and his group showed that lead acetate induced mutagenicity at a toxic dose at the *E. coli gpt* locus transfected to V79 cells [205]. They also reported that toxic doses of lead acetate and lead nitrate induced DNA breaks at the *E. coli gpt* locus transfected to V79 cells [205]. Another study by Wise and his collaborators found no evidence for direct genotoxic or DNA-damaging effects of lead except for lead chromate. They pointed out that the genotoxicity may be due to hexavalent chromate rather than lead [206].

Mercury

Environmental Occurrence, Industrial Production and Use

Mercury is a heavy metal belonging to the transition element series of the periodic table. It is unique in that it exists or is found in nature in three forms (elemental, inorganic, and organic), with each having its own profile of toxicity [207]. At room temperature elemental mercury exists as a liquid which has a high vapor pressure and is released into the environment as mercury vapor. Mercury also exists as a cation with oxidation states of +1 (mercurous) or +2 (mercuric) [208]. Methylmercury is the most frequently encountered compound of the organic form found in the environment, and is formed as a result of the methylation of inorganic (mercuric) forms of mercury by microorganisms found in soil and water [209].

Mercury is a widespread environmental toxicant and pollutant which induces severe alterations in the body tissues and causes a wide range of adverse health effects [210]. Both humans and animals are exposed to various chemical forms of mercury in the environment. These include elemental mercury vapor (Hg^0), inorganic mercurous (Hg^{+1}), mercuric (Hg^{+2}), and the organic mercury compounds [211]. Because mercury is ubiquitous in the environment, humans, plants and animals are all unable to avoid exposure to some form of mercury [212].

Mercury is utilized in the electrical industry (switches, thermostats, batteries), dentistry (dental amalgams), and numerous industrial processes including the production of caustic soda, in nuclear reactors, as antifungal agents for wood processing, as a solvent for reactive and precious metal, and as a preservative of pharmaceutical products [213]. The industrial demand for mercury peaked in 1964 and began to sharply decline between 1980 and 1994 as a result of federal bans on mercury additives in paints, pesticides, and the reduction of its use in batteries [214].

Potential for Human Exposure

Humans are exposed to all forms of mercury through accidents, environmental pollution, food contamination, dental care, preventive medical practices, industrial and agricultural operations, and occupational operations [215]. The major sources of chronic, low level mercury exposure are dental amalgams and fish consumption. Mercury enters water as a natural process of off-gassing from the earth's crust and also through industrial pollution [216]. Algae and bacteria methylate the mercury entering the waterways. Methyl mercury then makes its way through the food chain into fish, shellfish, and eventually into humans [217].

The two most highly absorbed species are elemental mercury (Hg^0) and methyl mercury (MeHg). Dental amalgams contain over 50% elemental mercury [218]. The elemental vapor is highly lipophilic and is effectively absorbed through the lungs and tissues lining the mouth. After Hg^0 enters the blood, it rapidly passes through cell membranes, which include both the blood-brain barrier and the placental barrier [219]. Once it gains entry into the cell, Hg^0 is oxidized and becomes highly reactive Hg^{2+}. Methyl mercury derived from eating fish is readily absorbed in the gastrointestinal tract and because of its lipid solubility, can easily cross both the placental and blood-brain barriers. Once mercury is absorbed it has a very low excretion rate. A major proportion of what is absorbed accumulates in the kidneys, neurological tissue and the liver. All forms of mercury are toxic and their effects include gastrointestinal toxicity, neurotoxicity, and nephrotoxicity [213].

Molecular Mechanisms of Mercury Toxicity and Carcingenicity

The molecular mechanisms of toxicity of mercury are based on its chemical activity and biological features which suggest that oxidative stress is involved in its toxicity [220]. Through oxidative stress mercury has shown mechanisms of sulfhydryl reactivity. Once in the cell both Hg^{2+} and MeHg form covalent bonds with cysteine residues of proteins and deplete cellular antioxidants. Antioxidant enzymes serve as a line of cellular defense against mercury compounds [221]. The interaction of mercury compounds suggests the production of oxidative damage through the accumulation of reactive oxygen species (ROS) which would normally be eliminated by cellular antioxidants.

In eukaryotic organisms the primary site for the production of reactive oxygen species (ROS) occurs in the mitochondria through normal metabolism [222]. Inorganic mercury has been reported to increase the production of these ROS by causing defects in oxidative phosphorylation and electron transport at the ubiquinone-cytochrome b5 step [223]. Through the acceleration of the rate of electron transfer in the electron transport chain in the mitochondria, mercury induces the premature shedding of electrons to molecular oxygen which causes an increase in the generation of reactive oxygen species [224].

Oxidative stress appears to also have an effect on calcium homeostasis. The role of calcium in the activation of proteases, endonucleases and phospholipases is well established. The activation of phospholipase A_2 has been shown to result in an increase in reactive oxygen species through the increase generation of arachidonic acid. Arachidonic acid has also been shown to be an important target of reactive oxygen species [225]. Both organic and inorganic mercury have been shown to alter calcium homeostasis but through different mechanisms. Organic mercury compounds (MeHg) are believed to increase intracellular calcium by accelerating the influx of calcium from the extracellular medium and mobilizing intracellular stores, while inorganic mercury (Hg^{2+}) compounds increase intracellular calcium stores only through the influx of calcium from the extracellular medium [226]. Mercury compounds have also been shown to induce increased levels of MDA in both the livers, kidneys, lungs and testes of rats treated with $HgCl_2$ [227]. This increase in concentration was shown to correlate with the severity of hepatotoxicity and nephrotoxicity [228]. $HgCl_2$-induced lipid peroxidation was shown to be significantly reduced by antioxidant pretreatment with selenium. Selenium has been shown to achieve this protective effect through direct binding to mercury or serving as a cofactor for glutathione peroxidase and facilitating its ability to scavenge ROS [229]. Vitamin E has also been reported to protect against $HgCl_2$-induced lipid peroxidation in the liver [230].

Metal-induced carcinogenicity has been a research subject of great public health interest. Generally, carcinogenesis is considered to have three stages including initiation, promotion, and progression and metastasis. Although mutations of DNA, which can activate oncogenesis or inhibit tumor suppression, were traditionally thought to be crucial factors for the initiation of carcinogenesis, recent studies have demonstrated that other molecular events such as transcription activation, signal transduction, oncogene amplification, and recombination, also constitute significant contributing factors [231, 232]. Studies have shown that mercury and other toxic metals effect cellular organelles and adversely affect their biologic functions [231, 233]. Accumulating evidence also suggests that ROS play a major role in the mediation of metal-induced cellular responses and carcinogenesis [234–236].

The connection between mercury exposure and carcinogenesis is very controversial. While some studies have confirmed its genotoxic potential, others have not shown an association between mercury exposure and genotoxic damage [237]. In studies implicating mercury as a genotoxic agent, oxidative stress has been described has the molecular mechanism of toxicity. Hence, mercury has been shown to induce the formation of ROS known to cause DNA damage in cells, a process which can lead to the initiation of carcinogenic processes [238, 239]. The direct action of these free radicals on nucleic acids may generate genetic mutations. Although mercury-containing compounds are not mutagenic in bacterial assays, inorganic mercury has been shown to induce mutational events in eukaryotic cell lines with doses as low as 0.5 μM [240]. These free radicals may also induce conformational changes in proteins that are responsible for DNA repair, mitotic spindle, and chromosomal segregation [241]. To combat these effects, cells have antioxidant mechanisms that work to correct and avoid the formation of ROS (free radicals) in excess. These antioxidant mechanisms involve low molecular weight compounds such as vitamins C and E, melatonin, glutathione, superoxide dismutase, catalase, glutathione peroxidase and glutathione reductase that protect the cells by chelating mercury and reducing its oxidative stress potential [242].

Glutathione levels in human populations exposed to methylmercury intoxication by eating contaminated fish have been shown to be higher than normal [243]. These studies were also able to confirm a direct and positive correlation between mercury and glutathione levels in blood. They also confirmed an increased mitotic index and polyploidal aberrations associated with mercury exposure [243]. Epidemiological studies have demonstrated that enzymatic activity was altered in populations exposed to mercury; producing genotoxic alterations, and suggesting that both chronic and relatively low level mercury exposures may inhibit enzyme activity and induce oxidative stress in the cells [244]. There is no doubt that the connection between mercury exposure and carcinogenesis is very controversial. However, *in-vitro* studies suggest that the susceptibility to DNA damage exists as a result of cellular exposure to mercury. These studies also indicate that mercury-induced toxicity and carcinogenicity may be cell-, organ- and/or species- specific.

Prospects

A comprehensive analysis of published data indicates that heavy metals such as arsenic cadmium, chromium, lead, and mercury, occur naturally. However, anthropogenic activities contribute significantly to environmental contamination. These metals are systemic toxicants known to induce adverse health effects in humans, including cardiovascular diseases, developmental abnormalities, neurologic and neurobehavioral disorders, diabetes, hearing loss, hematologic and immunologic disorders, and various types of cancer. The main pathways of exposure include ingestion, inhalation, and dermal contact. The severity of adverse health effects is related to the type of heavy metal and its chemical form, and is also time- and dose-dependent. Among many other factors, speciation plays a key role in metal toxicokinetics and toxicodynamics, and is highly influenced by factors such as valence state, particle size, solubility, biotransformation, and chemical form. Several studies have shown that toxic metals exposure causes long term health problems in human populations. Although the acute and chronic effects are known for some metals, little is known about the health impact of mixtures of toxic elements. Recent reports have pointed out that these toxic elements may interfere metabolically with nutritionally essential metals such as iron, calcium, copper, and zinc [245, 246]. However, the literature is scarce regarding the combined toxicity of heavy metals. Simultaneous exposure to multiple heavy metals may produce a toxic effect that is either additive, antagonistic or synergistic.

A recent review of a number of individual studies that addressed metals interactions reported that co-exposure to metal/metalloid mixtures of arsenic, lead and cadmium produced more severe effects at both relatively high dose and low dose levels in a biomarker-specific manner [247]. These effects were found to be mediated by dose, duration of exposure and genetic factors. Also, human co-exposure to cadmium and inorganic arsenic resulted in a more pronounced renal damage than exposure to each of the elements alone [248]. In many areas of metal pollution, chronic low dose exposure to multiple elements is a major public health concern. Elucidating the mechanistic basis of heavy metal interactions is essential for health risk assessment and management of chemical mixtures. Hence, research is needed to further elucidate the molecular mechanisms and public health impact associated with human exposure to mixtures of toxic metals.

St. Louis, Missouri 63105

Subject: Phase I Environmental Site Assessment
Fox Shores Apartments
400 Fox Shores Drive
Kaukauna, Wisconsin 54130
Partner Project No. 18-215232.1

Dear Mr. LaCroix:

Partner Engineering and Science, Inc. (Partner) is pleased to provide the results of the *Phase I Environmental Site Assessment* (Phase I ESA) report of the abovementioned address (the "subject property"). This assessment was performed in conformance with the scope and limitations as detailed in the ASTM Standard Practice E1527-13 Standard Practice for Environmental Site Assessments.

This assessment included a site reconnaissance on June 14, 2018 as well as research and interviews with representatives of the public, property ownership, site manager, and regulatory agencies. The regulatory assessment activities were initiated on June 12, 2018. An assessment was made, conclusions stated, and recommendations outlined.

We appreciate the opportunity to provide environmental services to Berkadia Commercial Mortgage LLC. If you have any questions concerning this report, or if we can assist you in other matter, please contact me at (214) 234-9561.

Sincerely,

DRAFT

Scott Chiu
National Client Manager

Subject: Phase I Environmental Site Assessment
Fox Shores Apartments
400 Fox Shores Drive
Kaukauna, Wisconsin 54130
Partner Project No. 18-215232.1

Dear Mr. LaCroix:

Partner Engineering and Science, Inc. (Partner) is pleased to provide the results of the *Phase I Environmental Site Assessment* (Phase I ESA) report of the abovementioned address (the "subject property"). This assessment was performed in conformance with the scope and limitations as detailed in the ASTM Standard Practice E1527-13 Standard Practice for Environmental Site Assessments.

This assessment included a site reconnaissance on June 14, 2018 as well as research and interviews with representatives of the public, property ownership, site manager, and regulatory agencies. The regulatory assessment activities were initiated on June 12, 2018. An assessment was made, conclusions stated, and recommendations outlined.

We appreciate the opportunity to provide environmental services to Berkadia Commercial Mortgage LLC. If you have any questions concerning this report, or if we can assist you in other matter, please contact me at (214) 234-9561.

Sincerely,

Scott Chiu
National Client Manager

EXECUTIVE SUMMARY

Partner Engineering and Science, Inc. (Partner) has performed a Phase I Environmental Site Assessment (ESA) in accordance with the scope of work and limitations of ASTM Standard Practice E1527-13, the Environmental Protection Agency Standards and Practices for All Appropriate Inquiries (AAI) (40 CFR Part 312) for the property located at 400 Fox Shores Drive in the City of Kaukauna, Outagamie County, Wisconsin (the "subject property"). The Phase I Environmental Site Assessment is designed to provide Berkadia Commercial Mortgage LLC with an assessment concerning environmental conditions (limited to those issues identified in the report) as they exist at the subject property.

Property Description

The subject property is located to the north and west of Fox Shores Drive within a mixed commercial and residential area of Kaukauna, Wisconsin. Please refer to the table below for further description of the subject property:

Subject Property Data	
Address(es):	400 Fox Shores Drive, Kaukauna, Wisconsin
Property Use:	Multi-Family
Land Acreage (Ac):	2.185 Ac
Number of Buildings:	6
Number of Floors:	2 (no basement)
Auxiliary Buildings	400 Fox Shores Garage Bays 1-6 (1,300 SF); 400 Fox Shores Garage Bays 7-12 and maintenance (1,600 SF); 410 Fox Shore Garage Bays 1-6 (1,300 SF); 410 Fox Shore Garage Bays 7-12 (1,300 SF); 400 and 410 Bicentennial Court Garage Bays 1-7 (1,500 SF); 380 and 390 Bicentennial Court Garage Bays 1-7 (1,500 SF)
Gross Building Area (SF):	67,060 SF
Date of Construction:	1983 (Bicentennial Court buildings); 1992 (Fox Shores buildings)
Assessor's Parcel Number (APN):	323-0408-00; 323-0408-01; 323-0408-02
Type of Construction:	Wood-Framed
Number of Units:	56
Current Tenants:	Fox Shores Apartments
Site Assessment Performed By:	John Hetner of Partner
Site Assessment Conducted On:	June 14, 2018
HUD Program:	MAP 223f*

HUD Part 50 Form, Partner Worksheets and supporting documentation are included under a separate cover and provided concurrent with the Phase I ESA outlined herein.

The subject property is currently occupied by the Fox Shores Apartments for residential use. Onsite operations consist of general residential operations and maintenance activities. In addition to the current structures, the subject property is also improved with paved-parking areas and limited landscaping.

According to available historical sources, the subject property was formerly developed as early as circa 1890. Development activities, as depicted on Sanborn fire insurance maps, indicate the subject property

and vicinity were developed as part of the Chicago and Northwest Rail Road Shops. Numerous structures were developed on the subject property between approximately 1890 until at least 1971 per historical aerial imagery. Aerial imagery depicts the site as undeveloped in 1982. Tax assessor documents indicate development of the subject property began in 1983 with the development of the existing multi-family residential structures along Bicentennial Court. A second phase of residential structures were developed in 1992 along Fox Shores Drive.

Sanborn fire insurance maps provide the best indication of historical tenancy during the period of time the subject property was occupied by a railroad service yard. The 1925 Sanborn map depicts a carpentry shop, machine shop, repair shop, engine room, coal room, blacksmith shop, supply warehouses, tin shop, and pipe shed. It is assumed that these occupants and structures existed at the subject property throughout the period (*c. 1890-1971*) the subject property was developed for railroad services. From 1983 to present, the subject property has been occupied by residential tenants.

The immediately surrounding properties consist of the Fox River to the north; an operations facility occupied by the City of Kaukauna Street and Park Department used to store vehicles and equipment to the south across Bicentennial Court; a fitness center to the east across Fox Shores Drive; and an apartment complex to the west.

According to a 2006 Phase II Subsurface Investigation conducted at the south adjacent property and correspondence with the Wisconsin Department of Natural Resources, the depth and direction of groundwater in the vicinity of the subject property is inferred to be approximately 5-feet below ground surface (bgs) and flow toward the southeast.

Findings – ASTM Items

6.3	Adjacent Properties				**X**		

**BER - Business Environmental Risk*

A *recognized environmental condition (REC)* refers to the presence or likely presence of any hazardous substances or petroleum products in, on, or at a property: due to release to the environment; under conditions indicative of a release to the environment; or under conditions that pose a material threat of a future release to the environment.

- The west adjacent property, identified as the USACE – Parcel J (Kaukauna Power Canal) is an open Environmental Repair Program (ERP) case on the online Wisconsin Bureau for Redevelopment and Remediation Tracking (WI BRRTS) database. The site's address is identified as the "end of 420 Bicentennial Court". The responsible party for this site is listed at the United States Army Corps of Engineers (USACE). According to Wisconsin Department of Natural Resources (WI DNR) records, the constituent of concern for this site is identified as lead and impacts are known to be present in the soil media. The case was opened and responsible party notified on March 1, 2003. To date, no remedial activities have occurred. Per correspondence with the WI DNR case manager assigned to site, the USACE has not made efforts to pursue remediation of the site. Parcel J, as depicted on a sampling map obtained from the WI DNR, encompasses the shoreline of the Fox River beginning to the west of the subject property and extends eastward toward the subject property, ultimately concluding at the northeast corner of the subject property. In total, this site represents the north and northwest adjacent property. Soil sampling results from 2004 and 2005 subsurface investigation indicate elevated levels of lead immediately north and northwest of the subject property boundary along the Fox River shoreline.

  Limited information is available for the USACE – Parcel J site given the USACE's denial of responsibility for the contamination to date. Correspondence with WI DNR also indicated the site's priority level with the WI DNR does not qualify it for State funded remediation. As of the August 9, 2016 semi-annual status report, no action has been taken at the site. The WI DNR will continue to issue semi-annual status updates per WI DNR policy, however, at this time, no action is anticipated.

  Based on the known soil contamination abutting the northern and northwestern boundary of the subject property, this site represents a *recognized environmental condition (REC)* at the subject property.

A *controlled recognized environmental condition (CREC)* refers to a REC resulting from a past release of hazardous substances or petroleum products that has been addressed to the satisfaction of the applicable regulatory authority, with hazardous substances or petroleum products allowed to remain in place subject to the implementation of required controls. The following was identified during the course of this assessment:

- The property, identified as Ghost Town Fitness Center at 180 Fox Shores Drive, is located adjacent to the east of the subject property. This site is registered as an WI ERP site which originates from its listing on the WI DNR Environmental Cleanup and Brownfields Redevelopment (BRRTS) database. According to the EDR regulatory database and WI DNR files, groundwater contamination was identified at this property. Substances identified exceeding regulatory

reporting thresholds are listed as arsenic and selenium. The substances were identified through subsurface testing that occurred in 2006. An excerpt of the discussion from the limited subsurface investigation is provided below:

- *The NR 140 Permissible Allowable Limit (PAL) for arsenic is 1 microgram (µ) per liter. Arsenic was detected at a concentration of 7.8 micrograms per liter (µg/L) in the groundwater sample collected during the July 26, 2006 push-probe assessment and was detected at a concentration of 3.0 µg/L in the groundwater sample collected from the monitoring well on September 12, 2006. The NR 140 PAL for selenium is 10 µg/L. Selenium was detected at a concentration of 32 µg/L in the groundwater sample collected during the July 26, 2006 push-probe assessment and was detected at a concentration of 14.7 µg/L in the groundwater sample collected from the monitoring well on September 12, 2006. Lead was detected at a concentration of 5.8 µg/L during the July 26, 2006 push-probe assessment but was not detected in the groundwater sample collected from the monitoring well on September 12, 2006.*

Findings of the limited subsurface investigation were submitted to the WI DNR, along with the required documentation to obtain a closure letter from the State. Upon review of the limited subsurface investigation, the WI DNR granted closure to the site pursuant to an exemption to a PAL for a substance of public health concern (*Wisconsin Administrative Code s. NR 140.28(2)(b)*) given the following criteria were met at the site:

1. The measured or anticipated increase in the concentration of the substance will be minimized to the extent technically feasible and economically feasible;
2. Compliance with the PAL is either not technically or economically feasible;
3. The enforcement standard for the substance will not be attained or exceeded at the point of standards application; and
4. Any existing or projected increase in the concentration of the substance above the background concentration does not present a threat to public health or welfare.

Per a WI DNR *No Further Action Letter*, dated October 9, 2006, this case was granted closure with no further investigation, remediation or other action required at this site. The WI DNR granted closure to the site as the constituent levels of arsenic and selenium at the site were remediated to WI DNR standards in accordance with *Wisconsin Administrative Code s. NR 726.05*.

Based on the case closure and direction of groundwater flow identified through subsurface investigation, this site represents a *controlled recognized environmental condition (CREC)*.

- The property, identified as the Kaukauna Waste Oil Collection Site at 201 West 2nd Street, 222 3rd Street, and 3rd Street 200 Block, and is located adjacent to the south of the subject property beyond Bicentennial Court. This site reported a release of petroleum based fuels *circa 1993*, which reportedly impacted soil and groundwater. The release occurred as a result of leaking UST and was reported to the WI DNR on December 28, 1993. The responsible party for the release,

contamination and remediation is identified as the City of Kaukauna – Public Works Department. Remedial efforts at the subject property include soil excavation and the removal of two, 10,000-gallon USTs and one, 550-gallon waste oil UST. Regulatory documents obtained from the WI DNR indicate soil excavations around tank pits at ranging between 4′ and 13′ below ground surface. Groundwater gradient maps indicate groundwater flow to the east-southeast, away from the subject property.

As a result of the known contamination, soil and groundwater deed restrictions were placed on the property as indicated on the *Deed Restriction* recording document dated May 20, 2003. The Deed Restriction document states that natural attenuation has been approved by the WI DNR to remediate groundwater contamination exceeding *ch. NR 140 of the Wisconsin Administrative Code* for groundwater standards within the boundary of the deed-restricted property. Given the implementation of the Deed Restriction, further groundwater and soil remediation activities are considered unnecessary.

The responsible party submitted all required documentation pursuant to receiving a Final Case Closure letter from the WI DNR. As stated by the WI DNR, the responsible party complied with the conditions for closure, including submittal of the Deed Restriction, and as such, the WI DNR concluded, "Based on the correspondence and data provided, it appears that your case meets the screening criteria of s. *NR 746.07*, and the requirements of *ch. NR 726* of the Wisconsin Administrative Code. The Department considers this case closed and no further investigation, remediation or other action is required at this time."

Based on the case closure and the groundwater Deed Restriction, this site represents a *controlled recognized environmental condition (CREC)*

A *historical recognized environmental condition (HREC)* refers to a past release of any hazardous substances or petroleum products that has occurred in connection with the property and has been addressed to the satisfaction of the applicable regulatory authority or meeting unrestricted use criteria established by a regulatory authority, without subjecting the property to any required controls. The following was identified during the course of this assessment:

- Partner did not identify historical recognized environmental conditions during the course of this assessment.

An *environmental issue* (also referred to as *Business Environmental Risk*) refers to environmental concerns identified by Partner, which do not qualify as RECs; however, warrant further discussion. The following was identified during the course of this assessment:

- Partner did not identify environmental issues during the course of this assessment.

Conclusions, Opinions and Recommendations

Partner has performed a Phase I Environmental Site Assessment in conformance with the scope and limitations of ASTM Standard Practice E1527-13 of 400 Fox Shores Drive in the City of Kaukauna,

Outagamie County, Wisconsin (the "subject property"). Any exceptions to or deletions from this practice are described in Section 1.5 of this report.

This assessment has revealed evidence of recognized environmental conditions and/or environmental issues in connection with the subject property. Based on the conclusions of this assessment, Partner recommends the following:

- Given the known contamination of the surrounding properties as described in Section 4.2.2, a limited subsurface investigation should be conducted in order to evaluate the presence or absence of soil and/or groundwater contamination due at the subject property to the historical use of the subject property. Compliance with HUD MAP Guidelines, specifically Section 9.3, *Contamination Analysis,* will be addressed during and upon completion of the limited subsurface investigation.

1.0 INTRODUCTION

Partner Engineering and Science, Inc. (Partner) has performed a Phase I Environmental Site Assessment (ESA) in conformance with the scope and limitations of ASTM Standard Practice E1527-13 and the Environmental Protection Agency Standards and Practices for All Appropriate Inquiries (AAI) (40 CFR Part 312) for the property located at 400 Fox Shores Drive in the City of Kaukauna, Outagamie County, Wisconsin (the "subject property"). Any exceptions to, or deletions from, this scope of work are described in the report.

1.1 Purpose

The purpose of this ESA is to identify existing or potential Recognized Environmental Conditions (as defined by ASTM Standard E-1527-13) affecting the subject property that: 1) constitute or result in a material violation or a potential material violation of any applicable environmental law; 2) impose any material constraints on the operation of the subject property or require a material change in the use thereof; 3) require clean-up, remedial action or other response with respect to Hazardous Substances or Petroleum Products on or affecting the subject property under any applicable environmental law; 4) may affect the value of the subject property; and 5) may require specific actions to be performed with regard to such conditions and circumstances. In addition, a purpose of the Phase I ESA is to document compliance with 24 CFR 50.3(i), which states HUD's policy that all properties proposed for use in HUD programs be free of hazardous materials, contamination, toxic chemicals and gases, and radioactive substances, where a hazard could affect the health and safety of occupants or conflict with the intended utilization of the property. The *HUD Part 50 Form*, *HUD Partner Worksheets* and supporting documentation are included under a separate cover and provided concurrent with the Phase I ESA outlined herein.

The information contained in the ESA Report will be used by Client to: 1) evaluate its legal and financial liabilities for transactions related to foreclosure, purchase, sale, loan origination, loan workout or seller financing; 2) evaluate the subject property's overall development potential, the associated market value and the impact of applicable laws that restrict financial and other types of assistance for the future development of the subject property; and/or 3) determine whether specific actions are required to be performed prior to the foreclosure, purchase, sale, loan origination, loan workout or seller financing of the subject property.

This ESA was performed to permit the User to satisfy one of the requirements to qualify for the innocent landowner, contiguous property owner, or bona fide prospective purchaser limitations on scope of Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) (42 U.S.C. §9601) liability (hereinafter, the "landowner liability protections," or "LLPs"). ASTM Standards E-1527-13 and E-1527-13 constitutes "all appropriate inquiry into the previous ownership and uses of the property consistent with good commercial or customary practice" as defined at 42 U.S.C. §9601(35)(B).

In addition, a purpose of the Phase I ESA is to document compliance with 24 Code of Federal Regulations (CFR) 50.3(i)(1). An additional purpose is to determine the presence or absence of hazardous materials, contamination, toxic chemicals and gases, and radioactive substances, where a hazard could affect the health and safety of occupants or conflict with the intended utilization of the property.

1.2 Scope of Work

The scope of work for this ESA is in accordance with the requirements of ASTM Standard Practice E1527-13 Standard Practice for Environmental Site Assessments: Phase I Environmental Site Assessment Process; the Environmental Protection Agency Standards and Practices for All Appropriate Inquiries (AAI) (40 CFR Part 312). This assessment included: 1) a property and adjacent site reconnaissance; 2) interviews with key personnel; 3) a review of historical sources; 4) a review of regulatory agency records; 5) a review of a regulatory database report provided by a third-party vendor and 6) Client provided documents, if available.

1.3 Limitations

Partner warrants the findings and conclusions contained herein were accomplished in accordance with the methodologies set forth in the Scope of Work. These methodologies are described as representing good commercial and customary practice for conducting an ESA of a property for the purpose of identifying recognized environmental conditions. There is a possibility that even with the proper application of these methodologies there may exist on the subject property conditions that could not be identified within the scope of the assessment or which were not reasonably identifiable from the available information. Partner believes the information obtained from the record review and the interviews concerning the subject property is reliable. However, Partner cannot and does not warrant or guarantee the information provided by these other sources is accurate or complete. The conclusions and findings set forth in this report are strictly limited in time and scope to the date of the evaluations. The conclusions presented in the report are based solely on the services described therein, and not on scientific tasks or procedures beyond the scope of agreed-upon services or the time and budgeting restraints imposed by the Client. No other warranties are implied or expressed.

Some of the information provided in this report is based upon personal interviews, and research of available documents, records, and maps held by the appropriate government and private agencies. This report is subject to the limitations of historical documentation, availability, and accuracy of pertinent records, and the personal recollections of those persons contacted.

This practice does not address requirements of any state or local laws or of any federal laws other than the All Appropriate Inquiry provisions of the LLPs. Further, this report does not intend to address all of the safety concerns, if any, associated with the subject property.

Environmental concerns, which are beyond the scope of a Phase I ESA as defined by ASTM include the following: ACMs, LBP, radon, and lead in drinking water. These issues may affect environmental risk at the subject property and may warrant discussion and/or assessment; however, are considered non-scope issues.

These non-ASTM scope issues are discussed in the *HUD Part 50 Form*, *HUD Partner Worksheets* and supporting documentation, which are provided under a separate cover concurrent with this Phase I ESA.

1.4 User Reliance

Berkadia Commercial Mortgage LLC, as well as the U.S. Department of Housing and Urban Development, their employees, agents, successors, and assigns may rely upon this report in evaluating a request for an extension of credit (the "Mortgage Loan") to be secured by the subject property. This information also may be used by any actual or prospective purchaser, transferee, assignee, or servicer of the Mortgage Loan, any actual or prospective investor (including agent or advisor) in any securities evidencing a beneficial interest in or backed by the Mortgage Loan, any rating agency actually or prospectively rating any such securities, any indenture trustee, and any institutional provider(s) from time to time of any liquidity facility or credit support for such financing, provided that any such reliance by any of the foregoing is subject to the terms and conditions in place between Partner and its Client, which terms and conditions include (by way of illustration and not by way of limitation) a standard of care, a limitation of liability plus distribution and reliance restrictions and which terms and conditions, along with these limitations and reliance provisions shall be disclosed by Client to any and all of the foregoing who receive Partner's report. In addition, the Client and all of the foregoing realize and acknowledge hereby that providing Partner's report to any of the foregoing by the Client may create an actual or potential conflict of interest for Partner, and, as an essential pre-condition to such disclosure and receipt of this, or any Partner report, both the Client and all of the foregoing who may be in receipt of any Partner report agree to also waive any conflict of interest as to Partner or its employees, officers, directors or shareholders in connection with receipt of the Partner report by any of the foregoing. Reliance by any of the foregoing subject to the said terms and conditions and waiver of conflict of interest shall in no event increase Partner's total maximum aggregate liability regardless of the number of claims or claimants. In addition, this report, or a reference to this report, may be included or quoted in any offering circular, private placement memorandum, registration statement, or prospectus, and Partner agrees to cooperate in answering questions by any of the above parties in connection with a securitization or transaction involving the Mortgage Loan and/or such securities, provided that any such inclusion expressly sets out these terms and conditions, use limitations and reliance restrictions and waiver of conflict of interest provisions.

This report has been completed under specific **Terms and Conditions** relating to scope, relying parties, limitations of liability, indemnification, dispute resolution, and other factors relevant to any reliance on this report. Any parties relying on this report do so having accepted the Terms and Conditions for which this report was completed. A copy of Partner's standard **Terms and Conditions** can be found at http://www.partneresi.com/terms-and-conditions.php.

1.5 Limiting Conditions

The findings and conclusions contain all of the limitations inherent in these methodologies that are referred to in ASTM E-1527-13.

Specific limitations and exceptions to this ESA are more specifically set forth below:

- Partner was not able to document the historical use of the subject property prior to 1890. The general vicinity of the subject property is depicted as developed, however, site specific information is not shown on the map. Other sources of historical information, such as aerial imagery, topographic maps, and city directories do not provide coverage for the subject property prior to 1938. This data failure is not considered critical and does not change the conclusions of this report.

- Partner was unable to determine the property use at 5-year intervals, which constitutes a data gap. Except for property tax files and recorded land title records, which were not considered to be sufficiently useful, Partner reviewed all standard historical sources and conducted appropriate interviews.

- Partner submitted Freedom of Information Act (FOIA) requests to the Kaukauna City Clerk (City Health Department, Building Department, Fire Department) for information pertaining to hazardous substances, underground storage tanks, releases, inspection records, etc. for the subject property. As of this writing, the City Clerk has not responded to Partner's request. Based on information obtained from other historical sources, this limitation is not expected to alter the overall findings of this assessment. If issues of an environmental concern are identified upon review of these documents, Partner will issue an addendum to this report.

- Partner inspected approximately 25% of all interior units and all common areas. Based on the size and nature of use of the uninspected units, this limited method of inspection is not expected to alter the overall findings of this assessment.

The Client has requested the report despite the above-listed limitations.

2.0 SITE DESCRIPTION

2.1 Site Location and Legal Description

The subject property is located to the north and west of Fox Shores Drive within a mixed commercial and residential area of Kaukauna, Wisconsin. According to the Outagamie County Assessor, the subject property is comprised of three unique parcels. Abbreviated legal descriptions for the three parcels are described as follows:

- *CSM 307 Lot 2 (PLATTED OUT OF PRT LOT 1 CSM 59) .83AC M/L #1256329*
- *COM SE COR LT 1 CSM 155 N10D E43.02FT TO POB N10D E203.23FT S79D E104.54FT S54D E110FT S35D W225.23FT TO ST N 55D W76.22FT N57D W40.80FT TO POB ALSO DESC AS LOT 1 CSM VOL 2 PG 307 .83AC*
- *CSM 6200 LOT 1 (PLATTED OUT OF PRT GOV LOT 8 SEC21-21-8) 1.56AC M/L*

Ownership for the three parcels that comprise the subject property is listed as Fox Investments LLC.

Please refer to Figure 1: Site Location Map, Figure 2: Site Plan, Figure 3: Topographic Map, and Appendix A: Site Photographs for the location and site characteristics of the subject property.

2.2 Current Property Use

The subject property is currently occupied by the Fox Shores Apartments for multi-family use. Onsite operations consist of typical residential operations and maintenance activities.

The subject property is designated for residential development by the City of Kaukauna.

The subject property was not identified in the regulatory database report outlined herein.

2.3 Description of Subject Property Structures and Improvements

Subject Property Data	
Property Use:	Multi-Family
Land Acreage (Ac):	2.185 Ac
Number of Buildings:	Six (6)
Number of Floors:	Two (2) (no basement)
Gross Building Area (SF):	67,060 SF
Auxiliary Buildings:	400 Fox Shores Garage Bays 1-6 (1,300 SF); 400 Fox Shores Garage Bays 7-12 and maintenance (1,600 SF); 410 Fox Shore Garage Bays 1-6 (1,300 SF); 410 Fox Shore Garage Bays 7-12 (1,300 SF); 400 and 410 Bicentennial Court Garage Bays 1-7 (1,500 SF); 380 and 390 Bicentennial Court Garage Bays 1-7 (1,500 SF)
Date of Construction:	1983 (Bicentennial Court buildings); 1992 (Fox Shores buildings)
Type of Construction:	Wood-Framed

In addition to the current structures, the subject property is also improved with paved-parking surfaces and limited landscaping.

2.4 Current Use of Adjoining Properties

The subject property is located within a mixed commercial and residential area of Kaukauna, Wisconsin. During the vicinity reconnaissance, Partner observed the following land use on properties in the immediate vicinity of the subject property:

Immediately Surrounding Properties	
North:	Fox River
South:	Bicentennial Court beyond which is City of Kaukauna Street and Parks Department operations facility (206 West Third Street and 201 Reaume Avenue)
East:	Fox Shores Drive beyond which is Ghost Town Fitness Center (180 Fox Shores Drive)
West:	River Park Place Apartments (420 Bicentennial Court)

The adjacent property to the east was identified as a Wisconsin Emergency Repair Program (WI ERP) site in the regulatory database report and the adjacent property to the south was identified as an leaking underground storage tank (LUST) and activity and use limitation (AUL) site in the regulatory database. Additionally, while not described as a known address per current tax assessor records, the south adjacent property (listed in the EDR database under 201 West 2nd Street) is also identified as an aboveground storage tank (AST), Resource Conservation Recovery Act (RCRA) – Conditionally Exempt Small Quantity Generator (CESQG), State Hazardous Waste and Incident Management Sites (SHWIMS), SPILLS, Bureau of Remediation & Redevelopment Tracking System (BRRTS), FINDS, ECHO, and MANIFEST site.

The west adjacent site is identified on the Wisconsin Department of Natural Resources' (WI DNR) database of open cases. The lack of an associated listing on the EDR regulatory database may be attributed to the lack of physical address on the WI DNR's database. Per the WI DNR database, the west adjacent site is known as the USACE (United States Army Corps of Engineers)– Parcel J (Kaukauna Power Canal) and located at the end of 420 Bicentennial Court.

These sites, as further described in the regulatory database section of this report, represent a *Recognized Environmental Condition* at the subject property.

Please refer to Figure 2: Site Plan.

2.5 Physical Setting Sources

2.5.1 Topography

Topography Information	
Site Elevation:	657-feet above mean sea level (MSL)
Slope Characteristic:	Gently
Surface Runoff/Topographic Gradient:	Southeast
Information Source:	USGS *Kaukauna Wisconsin* Quadrangle 7.5-minute series topographic map

The subject property is depicted on the 2013 map as developed.

Please refer to Figure 3: Topographic Map.

2.5.2 Geology & Hydrology

Hydrology Information	
Formation:	The subject property is situated within the Eastern Ridges and Lowlands physiographic province of the State of Wisconsin
Description:	The topography of the eastern ridges and lowlands is controlled by cuestas. The westernmost ridge is the rather low, narrow cuesta formed by the resistant Lower Magnesian limestone. It is alluded to hereafter as the Magnesian cuesta. The eastern upland is the higher and broader cuesta of Niagara limestone. The intermediate Green Bay- Lake Winnebago- Rock River lowland lies upon the belt of Black River and Galena limestone, with the gentle back slope of the Magnesian cuesta for one wall and the steep escarpment of the Niagara cuesta for the other.
Closest Surface Water:	Fox River (north adjacent property)
Estimated Depth to First Occurrence of Groundwater:	5' bgs
Hydrogeologic Gradient:	Southeast
Information Source:	Wisconsin DNR (Subsurface investigation at south adjacent property)

** The groundwater flow direction and the depth to shallow, unconfined groundwater, if present, would likely vary depending upon seasonal variations in rainfall and other hydrogeological features. Without the benefit of onsite groundwater monitoring wells surveyed to a datum, groundwater depth and flow direction beneath the subject property cannot be directly ascertained.*

According to available information, a public water system operated by the Kaukauna Utilities Department (KUD) serves the subject property vicinity. According to a representative of the KUD, shallow groundwater directly beneath the subject property is not utilized for domestic purposes. The sources of public water for the City of Kaukauna is groundwater from five groundwater wells that are located through the city. The depths of the wells range from 500- to 850-feet below ground surface.

According to a Phase II Subsurface Investigation conducted at the south adjacent property and correspondence with the Wisconsin Department of Natural Resources, the depth and direction of groundwater in the vicinity of the subject property is inferred to be approximately 5-feet below ground surface (bgs) and flow toward the southeast.

2.5.3 Surface Water Drainage

Surface Water Drainage		
Item or Feature	**Observed**	**REC**
Stormwater	Yes	No
Stormwater Management Pond(s)	No	
Surface water bodies	No	
Other	No	

Storm water is removed from the subject property primarily by sheet flow action across the paved surfaces towards storm water drains located in the public right of way. The subject property is connected to a municipal owned and maintained sewer system.

No pits, ponds or lagoons were observed on the subject property.

2.5.4 Soils

Soil Characteristics	
Soil Type:	Udorthents
Description:	This unit consists of well drained to excessively drained soils along mainly the southern edge of Block Island adjacent to Block Island Sound in the Mohegan Bluff area. Wind, waves, and rain have eroded these soils and undercut areas on bluffs. Areas are long and narrow and mostly range from 10 to 200 acres.
Source Information:	USDA Natural Resources Conservation Service Web Soil Survey online database

No soil stability, erosion and drainage concerns were observed on the subject property during the site reconnaissance.

2.5.5 Flood Zone Information

Flood Zone/Descriptions	
Unshaded, Zone X	An area located outside of the 100-year and 500-year flood plains.
Source Information:	Federal Emergency Management Agency (FEMA), Flood Insurance Rate Map (FIRM), Community Panel Number 55087C0342D, dated July 22, 2010

Additional information and HUD requirements for HUD flood zone compliance are outlined within the *HUD Part 50 Form and Partner Flood Management Worksheet,* which are provided under a separate cover concurrent with this Phase I ESA.

3.0 HISTORICAL INFORMATION

Partner obtained historical use information about the subject property from a variety of sources, which are outlined within the *Reference Section* of this report. A chronological listing of the historical data found is summarized in the table below:

Historical Use Information		
Period/Date	**Source**	**Description/Use**
c. 1890-1971	Aerial Photographs, Interviews, Topographic Maps, Sanborn Maps, Regulatory Records	Industrial
1982	Aerial Photographs, Building Records, City Directories, Interviews, Previous Report, Sanborn Maps	Undeveloped
1983-Present	Aerial Photographs, Building Records, City Directories, Interviews, Onsite Observations	Multifamily Residential

According to available historical sources, the subject property was formerly developed as early as circa 1890. Development activities as depicted on Sanborn fire insurance maps indicate the subject property and vicinity were developed as part of the Chicago and Northwest Rail Road Shops. Numerous structures were developed on the subject property during between approximately 1890 until at least 1971 per historical aerial imagery. Aerial imagery depicts the site as undeveloped in 1982. Tax assessor documents indicate development of the subject property began in 1983 with the development of the existing multi-family residential structures along Bicentennial Court. A second phase of residential structures were developed in 1992 along Fox Shores Drive.;

Sanborn fire insurance maps provide the best indication of historical tenancy during the period of time the subject property was occupied by a railroad service yard. The 1925 Sanborn map depicts a carpentry shop, machine shop, repair shop, engine room, coal room, blacksmith shop, supply warehouses, tin shop, and pipe shed. It is assumed that these occupants and structures existed at the subject property throughout the period (*c. 1890-1971*) the subject property was developed for railroad services. From 1983 to present, the subject property has been occupied by residential tenants.

Potential environmental concerns were identified in association with the current or historic use of the subject property, as further discussed in Section 4.22.

3.1 Aerial Photograph Review

Partner obtained available aerial photographs of the subject property and surrounding area from Environmental Data Resources (EDR). The following observations were noted to be visible on the subject property and adjacent properties during the aerial photograph review:

Date: 1938	***Scale: 1"=500'***
Subject Property:	The subject property appears to be developed as part of a railroad service yard. Several buildings and smaller objects, which may be rail cars, are visible throughout the property.
North:	Fox River

South:	The south adjacent appears to be developed with industrial structures associated with the railroad service yard as well as residential structures
East:	The east adjacent appears to be developed with industrial structures that extend from the subject property and are part of the railroad service yard that encompasses the general vicinity of the subject property
West:	The west adjacent appears to be developed with extensions of the rail lines that originate from the east (subject property) and are associated with the railroad service yard that encompasses the general vicinity of the subject property

Date: 1952, 1957, 1964, 1971	***Scale: 1"=500'***
Subject Property:	No significant changes visible
North:	No significant changes visible
South:	No significant changes visible
East:	No significant changes visible
West:	No significant changes visible

Date: 1982	***Scale: 1"=500'***
Subject Property:	The structures appear to have been razed and the subject property appears vacant with the exception of the former foundations and drive lanes
North:	No significant changes visible
South:	Bicentennial Court appears to have been developed. Beyond Bicentennial Court appears to be a structure that resembles the existing City operations facility.
East:	The east adjacent appears to be vacant. Former structures appear to have been razed with the exception of foundations and drive lanes.
West:	The west adjacent appears to be developed with multi structures that resemble the existing apartment complex.

Date: 1986	***Scale: 1"=500'***
Subject Property:	The subject property appears to have been developed with four structures on the south side of the property that resemble the existing multi-family buildings.
North:	No significant changes visible
South:	No significant changes visible
East:	The east adjacent appears to have been developed with a single structure that resembles the existing commercial facility.
West:	No significant changes visible

Date: 1992	***Scale: 1"=500'***
Subject Property:	Additional structures appear to have been developed on the north side of the property that resemble the existing multi-family buildings.
North:	No significant changes visible
South:	No significant changes visible
East:	No significant changes visible
West:	No significant changes visible

Date: 2006, 2010, 2015	***Scale: 1"=500'***
Subject Property:	No significant changes visible
North:	No significant changes visible

South:	No significant changes visible
East:	No significant changes visible
West:	No significant changes visible

Copies of select aerial photographs are included in Appendix B of this report.

3.2 Sanborn Fire Insurance Maps

Partner reviewed the collection of Sanborn Fire insurance maps from Environmental Data Resources (EDR). The following observations were noted to be depicted on the subject property and adjacent properties during the fire insurance map review:

Date: 1890	
Subject Property:	The subject property is not depicted on the Sanborn map. However, based on the surrounding developments depicted, it can be inferred the subject property was developed as part of the railroad service yard that encompasses the general vicinity.
North:	Not depicted (Fox River)
South:	The south adjacent property is not depicted on the Sanborn map. However, based on what is provided on the map, it can be inferred that at least portions of the south adjacent property were occupied by railroad lines and a lumber yard.
East:	The east adjacent property is not entirely depicted on the Sanborn map. However, based on what is provided on the map, it can be inferred that the east adjacent property is occupied by railroad lines and railcar turn table
West:	The west adjacent property is not depicted on the Sanborn map.

Date: 1894, 1900	
Subject Property:	No significant changes depicted
North:	No significant changes depicted
South:	No significant changes depicted
East:	No significant changes depicted
West:	No significant changes depicted

Date: 1900	
Subject Property:	No significant changes depicted
North:	No significant changes depicted
South:	No significant changes depicted
East:	No significant changes depicted

Date: 1906	
Subject Property:	The subject property is depicted with multiple buildings associated with a railway service that occupies the general vicinity of the subject property. Specific notations on the Sanborn map include three warehouses and an office.
North:	Not depicted (Fox River)
South:	The south adjacent property is not depicted on the Sanborn map. However, based on what is provided on the map, it can be inferred that at least portions of the south adjacent property were occupied by railroad lines and a lumber yard.

East:	The east adjacent property is depicted as developed with a railway service that occupies the general vicinity. Specific depictions include a round house turn table (utilized for repositioning railcars for reverse transit), an oil housing structure, a machine shop, blacksmith shop, water tower and sand housing structure.
West:	The west adjacent property is not depicted on the Sanborn map. However, based on what is provided on the map, it can be inferred that at least portions of the west adjacent property were occupied by railroad lines

Date: 1913	
Subject Property:	The subject property is depicted with multiple buildings associated with a railway service that occupies the general vicinity of the subject property. Specific notations on the Sanborn map include a repair shop, carpentry shop, supply warehouses, pipe shed, machine shoe, blacksmith shop, and railroad lines.
North:	No significant changes depicted
South:	The south adjacent developments are now depicted as the Standard Oil Co. Several structures are depicted beyond multiple railroad lines.
East:	No significant changes depicted
West:	No significant changes depicted

Date: 1925, 1945, 1956	
Subject Property:	No significant changes depicted
North:	No significant changes depicted
South:	No significant changes depicted
East:	No significant changes depicted
West:	No significant changes depicted

Copies of reviewed Sanborn Maps are included in Appendix B of this report.

3.3 City Directories

Partner reviewed historical city directories obtained from Environmental Data Resources (EDR) for past names and businesses that were listed for the subject property and adjacent properties. The findings are presented in the following table:

City Directory Search for 400 Fox Shores Drive (Subject Property)	
Year(s)	**Occupant Listed**
1990	No Listing (400 Fox Shores Drive)
1992	Residential Listings (400 Fox Shores Drive)
1995	Residential Listings (400 Fox Shores Drive)
2000	Residential Listings (400 Fox Shores Drive)
2005	Residential Listings (400 Fox Shores Drive)
2010	Residential Listings (400 Fox Shores Drive)
2014	Residential Listings (400 Fox Shores Drive)

Based on the city directory review, no environmentally sensitive listings were identified for the subject property address. However, it should be noted that City Directory coverage was not identified prior to 1990; the subject property is known to have been developed dating back to circa 1890.

City Directory Search for Adjacent Properties	
Year(s)	**Occupant Listed**
1990	Physically Fit (180 Fox Shores Drive), Residential Listings (420 Bicentennial Court)
1992	Physically Fit (180 Fox Shores Drive), Residential Listings (420 Bicentennial Court)
1995	Jeffrey Eitting (180 Fox Shores Drive), Residential Listings (420 Bicentennial Court)
2000	Jeffrey Eitting (180 Fox Shores Drive), Residential Listings (420 Bicentennial Court)
2005	Ghost Town Fitness Center (180 Fox Shores Drive), Residential Listings (420 Bicentennial Court)
2010	Ghost Town Fitness Center (180 Fox Shores Drive), Residential Listings (420 Bicentennial Court)
2014	Ghost Town Fitness Center (180 Fox Shores Drive), Residential Listings (420 Bicentennial Court)

Based on the city directory review, no environmentally sensitive listings were identified for the adjacent property addresses. However, it should be noted that City Directory coverage was not identified prior to 1990; the adjacent properties area known to have been developed dating back to circa 1890.

Copies of reviewed city directories are included in Appendix B of this report.

3.4 Historical Topographic Maps

Partner reviewed historical topographic maps obtained from Environmental Data Resources (EDR). The following observations were noted to be depicted on the subject property and adjacent properties during the topographic map review:

Date: 1954/1955	
Subject Property:	Developed with multiple structures that resemble structures depicted in historical Sanborn maps
North:	Fox River
South:	Railroad lines beyond which is a developed area as indicated by red shading
East:	Developed with multiple structures that resemble structures depicted in historical Sanborn maps
West:	Railroad line

Date: 1974	
Subject Property:	No developments depicted
North:	No significant changes depicted
South:	Developed with rail lines and a single, rectangular structure
East:	No developments depicted
West:	No developments depicted

Date: 1984	
Subject Property:	No significant changes depicted

North:	No significant changes depicted
South:	No significant changes depicted
East:	No significant changes depicted
West:	Developed with two structures that resemble the current multi-family buildings

Date: 1995	
Subject Property:	Depicted as situated within a developed area as indicated by grey shading
North:	Depicted as situated within a developed area as indicated by grey shading
South:	Depicted as situated within a developed area as indicated by grey shading
East:	Depicted as situated within a developed area as indicated by grey shading
West:	Depicted as situated within a developed area as indicated by grey shading

Copies of reviewed topographic maps are included in Appendix B of this report.

4.0 REGULATORY RECORDS REVIEW

4.1 Regulatory Agencies

4.1.1 State Department

Regulatory Agency Data	
Name of Agency:	Wisconsin Department of Natural Resources (WI DNR)
Point of Contact:	Ms. Jennifer Borski (WI DNR Hydrogeologist - Remediation & Redevelopment Program / Environmental Management)
Agency Address:	625 East County Road Y, Suite 700, Oshkosh, Wisconsin 54901
Agency Phone Number:	(920) 424-7887
Date of Contact:	June 15 and 26, 2018
Method of Communication:	Online / Telephone / Email

Summary of Communication: No records regarding hazardous substance use, storage or releases, or the presence of USTs and AULs on the subject property were on file with the WI DNR. However, WI DNR records were obtained for the south, east and west adjacent properties. These files are further discussed in Section 4.2.

4.1.2 Health Department

Regulatory Agency Data	
Name of Agency:	Kaukauna City Clerk
Point of Contact:	Ms. Sally Kenney
Agency Address:	144 West Second Street, Kaukauna, Wisconsin 54130
Agency Phone Number:	(920) 766-6300
Date of Contact:	June 15, 2018
Method of Communication:	Email

Summary of Communication: As of the date of this report, Partner has not received a response from the Kaukauna City Clerk for inclusion in this report.

4.1.3 Fire Department

Regulatory Agency Data	
Name of Agency:	Kaukauna Fire Department (KFD) c/o Kaukauna City Clerk
Point of Contact:	Ms. Sally Kenney
Agency Address:	144 West Second Street, Kaukauna, Wisconsin 54130
Agency Phone Number:	(920) 766-6300
Date of Contact:	June 15, 2018

Method of Communication:	Email

Summary of Communication: As of the date of this report, Partner has not received a response from the Kaukauna City Clerk for inclusion in this report.

4.1.4 Building Department

Regulatory Agency Data	
Name of Agency:	Kaukauna Building Inspection Department (KBID)
Point of Contact:	Mr. Jon Oldenburg
Agency Address:	144 West Second Street, Kaukauna, Wisconsin 54130
Agency Phone Number:	(920) 766-6300
Date of Contact:	June 15, 2018
Method of Communication:	Email

Summary of Communication: As of the date of this report, Partner has not received a response from the KBID for inclusion in this report.

4.1.5 Planning Department

Regulatory Agency Data	
Name of Agency:	Kaukauna Planning Department (KPD)
Point of Contact:	Mr. Jason Holmes
Agency Address:	144 West Second Street, Kaukauna, Wisconsin 54130
Agency Phone Number:	(920) 766-6300
Date of Contact:	June 15, 2018
Method of Communication:	Email

As of the date of this report, Partner has not received a response from the KPD for inclusion in this report. Per the City of Kaukauna's zoning map, the subject property is zoned *CCD: Commercial Core District*. A description of this zoning ordinance is provided within the appendices of this report.

4.1.6 Assessor's Office

Regulatory Agency Data	
Name of Agency:	Outagamie County Assessor (OCA)
Agency Address:	320 South Walnut Street, Appleton, Wisconsin 54911
Agency Phone Number:	(920) 832-5665
Date of Contact:	June 15, 2018
Method of Communication:	Online

Summary of Communication: According to records reviewed, the subject property is identified by Assessor Parcel Numbers (APNs) 323040802, 323040801, and 323040800 and is currently owned by Fox Investments LLC.

4.1.7 Super Priority Lien Statutes

According to the Environmental Lien and AUL State Statutes via the internet, **http://environmental.netronline.com/lienStatutes.aspx**, the State of Wisconsin does currently maintain an environmental super lien law.

4.2 Regulatory Database Summary

Information from standard federal, state, county, and city environmental record sources was provided by Environmental Data Resources, Inc. (EDR), dated June 12, 2018. Data from governmental agency lists are updated and integrated into one database, which is updated as these data are released. The information contained in this report was compiled from publicly available sources and the locations of the subject property are plotted utilizing a geographic information system, which geocodes the subject property addresses. The accuracy of the geocoded locations is approximately +/-300 feet.

Radius Report Data

Database	Search Radius (mile)	Site	Adjacent Properties	Sites of Concern
Federal NPL or Delisted NPL Site	1.00	N	N	N
Federal CERCLIS Site	0.50	N	N	N
Federal CERCLIS-NFRAP Site	0.50	N	N	N
Federal RCRA CORRACTS Facility	1.00	N	N	N
Federal RCRA TSDF Facility	0.50	N	N	N
Federal RCRA Generators Site (LQG, SQG, CESQG)	0.25	N	N	N
Federal IC/EC Registries	0.50	N	N	N

4.2.1 Subject Property Listings

The subject property is not identified in the regulatory database report.

4.2.2 Adjacent Property Listings

The adjacent property to the east was identified as a WI ERP site in the regulatory database report as discussed below:

- The property, identified as Ghost Town Fitness Center at 180 Fox Shores Drive, is located adjacent to the east of the subject property. This site is registered as an WI ERP site which originates from its listing on the WI DNR Environmental Cleanup and Brownfields Redevelopment (BRRTS) database. According to the EDR regulatory database and WI DNR files, groundwater contamination was identified at this property. Substances identified exceeding regulatory reporting thresholds are listed as arsenic and selenium. The substances were identified through subsurface testing that occurred in 2006. An excerpt of the discussion from the limited subsurface investigation is provided below:
    - *The NR 140 PAL for arsenic is 1 microgram (µ) per liter. Arsenic was detected at a concentration of 7.8 µg/L in the groundwater sample collected during the July 26, 2006 push-probe assessment and was detected at a concentration of 3.0 µg/L in the groundwater sample collected from the monitoring well on September 12, 2006. The NR 140 PAL for selenium is 10 µg/L. Selenium was detected at a concentration of 32 µg/L in the groundwater sample collected during the July 26, 2006 push-probe assessment and was detected at a concentration of 14.7 µg/L in the groundwater sample collected from the monitoring well on September 12, 2006. Lead was detected at a concentration of 5.8 µg/L during the July 26, 2006 push-probe assessment but was not detected in the groundwater sample collected from the monitoring well on September 12, 2006.*

  Findings of the limited subsurface investigation were submitted to the WI DNR, along with the required documentation to obtain a closure letter from the State. Upon review of the limited subsurface investigation, the WI DNR granted closure to the site pursuant to an exemption to a PAL for a substance of public health concern (*Wisconsin Administrative Code s. NR 140.28(2)(b)*) given the following criteria were met at the site:

  1. The measured or anticipated increase in the concentration of the substance will be minimized to the extent technically feasible and economically feasible;
  2. Compliance with the PAL is either not technically or economically feasible;
  3. The enforcement standard for the substance will not be attained or exceeded at the point of standards application; and
  4. Any existing or projected increase in the concentration of the substance above the background concentration does not present a threat to public health or welfare.

Per a WI DNR *No Further Action Letter*, dated October 9, 2006, this case was granted closure with no further investigation, remediation or other action required at this site. The WI DNR granted closure to the site as the constituent levels of arsenic and selenium at the site were remediated to WI DNR standards in accordance with *Wisconsin Administrative Code s. NR 726.05*.

Based on the case closure and direction of groundwater flow identified through subsurface investigation, this site represents a *controlled recognized environmental condition (CREC)*.

The adjacent property to the south beyond Bicentennial Court was identified as an LUST, AST, RRCA-CESQG, SHWIMS, SPILLS, BRRTS, FINDS, ECHO, MANIFEST and AUL site in the regulatory database as discussed below:

- The property, identified as the Kaukauna Waste Oil Collection Site at 201 West 2nd Street, 222 3rd Street, and 3rd Street 200 Block, and is located adjacent to the south of the subject property beyond Bicentennial Court. This site reported a release of petroleum based fuels *circa 1993*, which reportedly impacted soil and groundwater. The release occurred as a result of leaking UST and was reported to the WI DNR on December 28, 1993. The responsible party for the release, contamination and remediation is identified as the City of Kaukauna – Public Works Department. Remedial efforts at the subject property include soil excavation and the removal of two, 10,000-gallon USTs and one, 550-gallon waste oil UST. Regulatory documents obtained from the WI DNR indicate soil excavations around tank pits at ranging between 4' and 13' below ground surface. Groundwater gradient maps indicate groundwater flow to the east-southeast, away from the subject property.

  As a result of the known contamination, soil and groundwater deed restrictions were placed on the property as indicated on the *Deed Restriction* recording document dated May 20, 2003. The Deed Restriction document states that natural attenuation has been approved by the WI DNR to remediate groundwater contamination exceeding *ch. NR 140 of the Wisconsin Administrative Code* for groundwater standards within the boundary of the deed-restricted property. Given the implementation of the Deed Restriction, further groundwater and soil remediation activities are considered unnecessary.

  The responsible party submitted all required documentation pursuant to receiving a Final Case Closure letter from the WI DNR. As stated by the WI DNR, the responsible party complied with the conditions for closure, including submittal of the Deed Restriction, and as such, the WI DNR concluded, "Based on the correspondence and data provided, it appears that your case meets the screening criteria of s. *NR 746.07*, and the requirements of *ch. NR 726* of the Wisconsin Administrative Code. The Department considers this case closed and no further investigation, remediation or other action is required at this time."

  Based on the case closure and the groundwater Deed Restriction, this site represents a *controlled recognized environmental condition (CREC)*.

Additionally, while not listed in the EDR Regulatory Database, the west adjacent site, identified as the United States Army Corps of Engineers (USACE) – Parcel J (Kaukauna Power Canal) in the WI DNR BRRTS database is an open case as described below:

- The west adjacent property, identified as the USACE – Parcel J (Kaukauna Power Canal) is an open Environmental Repair Program (ERP) case on the online Wisconsin Bureau for Redevelopment and Remediation Tracking (WI BRRTS) database. The site's address is identified as the "end of 420 Bicentennial Court". The responsible party for this site is listed at the United States Army Corps of Engineers (USACE). According to Wisconsin Department of Natural Resources (WI DNR) records, the constituent of concern for this site is identified as lead and impacts are known to be present in the soil media. The case was opened and responsible party notified on March 1, 2003. To date, no remedial activities have occurred. Per correspondence with the WI DNR case manager assigned to site, the USACE has not made efforts to pursue remediation of the site. Parcel J, as depicted on a sampling map obtained from the WI DNR, encompasses the shoreline of the Fox River beginning to the west of the subject property and extends eastward toward the subject property, ultimately concluding at the northeast corner of the subject property. In total, this site represents the north and northwest adjacent property. Soil sampling results from 2004 and 2005 subsurface investigation indicate elevated levels of lead immediately north and northwest of the subject property boundary along the Fox River shoreline.

  Limited information is available for the USACE – Parcel J site given the USACE's denial of responsibility for the contamination to date. Correspondence with WI DNR also indicated the site's priority level with the WI DNR does not qualify it for State funded remediation. As of the August 9, 2016 semi-annual status report, no action has been taken at the site. The WI DNR will continue to issue semi-annual status updates per WI DNR policy, however, at this time, no action is anticipated.

  Based on the known soil contamination abutting the northern and northwestern boundary of the subject property, this site represents a *recognized environmental condition (REC)* at the subject property.

Given the known contamination of the surrounding properties described above, Partner recommends a limited subsurface investigation should be conducted in order to evaluate the presence or absence of soil and/or groundwater contamination due at the subject property to the historical use of the subject property. Compliance with HUD MAP Guidelines, specifically Section 9.3, Contamination Analysis, will be addressed during and upon completion of the limited subsurface investigation.

4.2.3 Sites of Concern Listings

No other sites of concern are identified in the regulatory database report.

4.2.4 Orphan Listings

The property to the south is identified as the Kaukauna Waste Oil Collection Site at 3rd Street 200 Block in the regulatory database report, as previously discussed in Section 4.2.2.

4.2.5 Vapor Intrusion

Partner has performed a Vapor Intrusion Assessment (Tier 1 Screen) in accordance with the scope of work and limitations of ASTM Standard Practice E 2600-10 for the subject property. The purpose of this Vapor Intrusion Assessment (Tier 1 Screen) was to identify existing or potential Vapor Intrusion Conditions (*pVIC*) (as defined by ASTM Standard E 2600-10) affecting the subject property. The initial Tier 1 Vapor Encroachment Screen (VES) has been completed in accordance with the above stated requirements. The data and research completed as part of this Phase I ESA Report was also utilized in the review of the potential for a Vapor Encroachment Condition (VEC) and included the following sources:

- USGS Topographic Map
- Historical Aerial Photographs
- EDR Regulatory Database
- Subject property and Vicinity Photographs
- Interviews

Vapor intrusion additional criteria

Question	Response	Comments
1. Is the property known to have current or past contamination?	No	None reported
2. Is contamination of the property suspected?	**Yes**	See Section 4.2.2
3. Is an adjacent property known to have current or past contamination which may have impacted the subject property?	**Yes**	See Section 4.2.2
4. Is a nearby property known to have current or past contamination which may have impacted the subject property?	**Yes**	See Section 4.2.2
5. Is regional groundwater contamination known to exist beneath the property?	No	None reported
6. Are you aware of other conditions which may result in vapor intrusion at the property?	No	None reported

A Vapor Encroachment worksheet and Vapor Encroachment Screen (VES) was completed by Partner and provided by EDR. The VES was performed using Tier 1 non-invasive screening pursuant to ASTM E 2600-10 "Standard Guide for Vapor Encroachment Screening on Property Involved in Real Estate Transactions, Section 8". Based on the findings of the Tier I screen and VES, vapor intrusion cannot be ruled out. As such, additional assessment is recommended.

A copy of the EDR regulatory database report and completed VES are included with the HUD Partner Worksheets, which are provided under a separate cover concurrent with this Phase I ESA.

5.0 USER PROVIDED INFORMATION AND INTERVIEWS

In order to qualify for one of the *Landowner Liability Protections (LLPs)* offered by the Small Business Liability Relief and Brownfields Revitalization Act of 2001 (the *Brownfields Amendments*), the *User* must provide the following information (if available) to the *environmental professional*. Failure to provide this information could result in a determination that *all appropriate inquiry* is not complete. The user is asked to provide information or knowledge of the following:

- Environmental cleanup liens that are filed or recorded against the site.
- Activity and land use limitations that are in place on the site or that have been filed or recorded in a registry.
- Specialized knowledge or experience of the person seeking to qualify for the LLPs.
- Relationship of the purchase price to the fair market value of the *property* if it were not contaminated.
- Commonly known or *reasonably ascertainable* information about the *property*.
- The degree of obviousness of the presence or likely presence of contamination at the *property*, and the ability to detect the contamination by appropriate investigation.
- The reason for preparation of this Phase I ESA.

Fulfillment of these user responsibilities is key to qualification for the identified defenses to CERCLA liability. Partner requested our Client to provide information to satisfy User Responsibilities as identified in Section 6 of the ASTM guidance.

Pursuant to ASTM E 1527-13, Partner requested the following site information from Berkadia Commercial Mortgage LLC (User of this report). Copies of pertinent documents are included in Appendix B of this report.

User Responsibilities				
Item	**Provided By User**	**Not Provided By User**	**Discussed Below**	**Does Not Apply**

Actual Knowledge	**X**		**X**	
Valuation Reduction for Environmental Issues	**X**		**X**	
Identification of Key Site Manager	**Section 5.1.3**			
Reason for Performing Phase I ESA	**Section 1.1**			
Prior Environmental Reports	**Section 5.2.6**		**X**	
Other				**X**

5.1 Interviews

5.1.1 Interview with Owner

According to Mr. Thomas Vandeyacht, representative of the subject property owner, the subject property was developed in 1983 and 1991 for residential use. Prior to that, the subject property was occupied by a railway service yard. Mr. Vandeyacht further stated there are no USTs, ASTs, clarifiers, oil/water separators, groundwater monitoring wells, or hazardous substance use/storage/generation on the subject property to the best of his knowledge.

5.1.2 Interview with Report User

Please refer to Section 5.2 below for information requested from the Report User. The information requested was not received prior to the issuance of this report. Because the Report User (Client) is a lender, it is understood the Report User would not have knowledge of the property that would significantly impact our ability to satisfy the objectives of this assessment. The lack of this information is not considered to represent a significant data gap.

5.1.3 Interview with Key Site Manager

Mr. Vandeyacht, key site manager, indicated that he information pertaining to pending, threatened, or past litigation relevant to hazardous substances or petroleum products in, on, or from the subject property; pending, threatened, or past administrative proceedings relevant to hazardous substances or petroleum products in, on, or from the subject property; or notices from a governmental entity regarding possible violation of environmental laws or possible liability relating to hazardous substances or petroleum products.

Mr. Vandeyacht completed the environmental site questionnaires provided by Partner for the subject property. According to Mr. Vandeyacht and as noted in the completed questionnaires, no proposed and/or existing stationary tank(s) containing explosive or fire-prone materials of 100-gallons or larger are located and/or planned for the subject property. Furthermore, no environmental concerns/issues were noted in the completed questionnaires. Mr. Vandeyacht did note the presence of one irrigation well at the subject property. A copy of the completed questionnaires is included within the appendices.

5.1.4 Interviews with Past Owners, Operators and Occupants

Interviews with past owners, operators and occupants were not conducted since information regarding the potential for contamination at the subject property was obtained from other sources.

5.1.5 Interview with Others

As the subject property is not an abandoned property as defined in ASTM 1527-13, interview with others were not performed.

5.2 User Provided Information

5.2.1 Title Records, Environmental Liens, and AULs

Partner was not provided with title records or environmental lien and AUL information for review as part of this assessment.

5.2.2 Specialized Knowledge

No specialized knowledge of environmental conditions associated with the subject property was provided by the User at the time of the assessment.

5.2.3 Actual Knowledge of the User

No actual knowledge of environmental lien or AULs encumbering the subject property or in connection with the subject property was provided by the User at the time of the assessment.

5.2.4 Valuation Reduction for Environmental Issues

No knowledge of valuation reductions associated with the subject property was provided by the User at the time of the assessment.

5.2.5 Commonly Known or Reasonably Ascertainable Information

The User did not provide information that is commonly known or *reasonably ascertainable* within the local community about the subject property at the time of the assessment.

5.2.6 Previous Reports and Other Provided Documentation

The following information was provided to Partner for review during the course of this assessment:

Phase I Environmental Site Assessment, Global Realty Services Group (January 26, 2010)

Global Realty Services Group (GRS) prepared this report on behalf of Alliant Capital LLC. The assessment was performed in accordance with ASTM Standard E1527-05. The assessment consisted of a site reconnaissance, interviews with knowledgeable personnel, review of historical information, and a review of federal, state and local regulatory databases. Pertinent information contained in this report is summarized below:

- At the time of the 2010 assessment, the subject property was occupied by the current Fox Shores Apartments
- According to the GRS report, the subject property formerly occupied by a railyard and railroad roundhouse
- No current or former ASTs or USTs were identified on the subject property.

GRS identified the east adjacent property (Ghost Town Fitness Center) as an HREC. No RECs and recommended no further investigation.

Copies of pertinent pages reviewed are included in Appendix B of this report.

6.0 SITE RECONNAISSANCE

The weather at the time of the site visit was sunny and clear. Refer to Section 1.5 for limitations encountered during the field reconnaissance and Sections 2.1 and 2.2 for subject property operations. The table below provides the site assessment details:

Site Assessment Data	
Site Assessment Performed By:	John Hetner
Site Assessment Conducted On:	June 14, 2018

The table below provides the subject property personnel interviewed during the field reconnaissance:

Site Visit Personnel for 400 Fox Shores Drive (Subject Property)			
Name	**Title/Role**	**Contact Number**	**Site Walk* Yes/No**
Mr. Thomas Vandeyacht	Key Site Manager	(903) 213-7145	Yes

* Accompanied Partner during the field reconnaissance activities and provided information pertaining to the current operations and maintenance of the subject property

The subject property is currently occupied by the Fox Shores Apartments for residential use. Onsite operations consist of typical residential operations and maintenance activities.

No environmental concerns were identified attributed to the current use of the subject property.

Partner observed all common areas, down units, vacant units and 25% of the occupied, residential units listed below:

DWELLING UNITS OBSERVED		
Bldg./Unit Number	**Type**	**Comments/Issue**
400 Fox Shores – 1	2 Bedroom/2 Bath	Good condition with no issues observed.
400 Fox Shores – 12	2 Bedroom/2 Bath	Good condition with no issues observed.
400 Fox Shores – 10	2 Bedroom/2 Bath	Good condition with no issues observed.
410 Fox Shores – 9	2 Bedroom/2 Bath	Good condition with no issues observed.
410 Fox Shores – 8	2 Bedroom/2 Bath	Good condition with no issues observed.
410 Fox Shores - 7	2 Bedroom/2 Bath	Good condition with no issues observed.
410 Bicentennial Court – 3	2 Bedroom/1 Bath	Good condition with no issues observed.
410 Bicentennial Court – 6	2 Bedroom/1 Bath	Good condition with no issues observed.
400 Bicentennial Court – 3	2 Bedroom/1 Bath	Good condition with no issues observed.
400 Bicentennial Court – 7	2 Bedroom/1 Bath	Good condition with no issues observed.
390 Bicentennial Court – 4	2 Bedroom/1 Bath	Good condition with no issues observed.
390 Bicentennial Court – 8	2 Bedroom/1 Bath	Good condition with no issues observed.
380 Bicentennial Court – 1	2 Bedroom/1 Bath	Good condition with no issues observed.
380 Bicentennial Court – 7	2 Bedroom/1 Bath	Good condition with no issues observed.

6.1 General Site Characteristics

6.1.1 Solid Waste Disposal

Solid Waste Disposal		
Item or Feature	**Observed**	**REC**
Trash, debris, and/or other waste materials	Yes	No
Dumping or disposal areas	No	
Construction/demolition debris and/or dumped fill dirt	No	
Landfilling activities	No	
Other	No	

Solid waste generated at the subject property is disposed of in commercial dumpsters located on the subject property. An independent solid waste disposal contractor removes solid waste from the subject property. According to property personnel, only household trash is collected in the on-site solid waste dumpsters. No evidence of illegal dumping of solid waste was observed during the Partner site reconnaissance.

6.1.2 Source of Heating and Cooling

Confirm the sources for heating and cooling with the site contact and/or owner as early as possible PRIOR TO the site visit and again DURING the site inspection. Certain regions of the country require fuel oil for heating, which can be stored in an AST or UST. If current tank is AST, be sure to investigate and rule out potential for former UST.

Source of Heating and Cooling			
Item or Feature	**Service Provider**	**Observed**	**REC**
Heating and/or cooling systems	Kaukauna Power and Light	Yes	No
Other (Hot Water)	Kaukauna Power and Light	Yes	No

Heating and cooling of the dwelling units is provided by electric baseboard heating strips. Cooling is provided by through-wall air conditioning units. Hot water is provided by central natural gas boiler units/individual natural gas/electric hot water heaters. The subject property contains individual 40-gallon electric powered water heaters located in utility closets in each dwelling unit.

6.1.3 Wells and Cisterns

Wells and Cisterns		
Item or Feature	**Observed**	**REC**
Potable wells	No	
Monitoring wells	No	
Irrigation wells	No	
Other	No	

No aboveground evidence of wells or cisterns was observed during the site reconnaissance.

6.1.4 Surface Water Drainage

Surface Water Drainage		
Item or Feature	**Observed**	**REC**
Stormwater	Yes	No
Surface water bodies	No	
Wetlands	No	
Other	No	

Storm water is removed from the subject property primarily by sheet flow action across the paved surfaces towards storm water drains located in the public right of way. The subject property is connected to a municipal owned and maintained sewer system.

6.1.5 Sewage Discharge and Disposal

Sewage Discharge and Disposal		
Item or Feature	**Observed**	**REC**
Septic system and/or leachfield	No	
Cesspools	No	
Wastewater treatment system	No	
Exterior pipe discharges and/or other effluent discharges	No	
Other	Yes	No

Sanitary discharges on the subject property are directed into the municipal sanitary sewer system. The City of Kaukauna services the subject property vicinity. No wastewater treatment facilities or septic systems are observed or reported on the subject property.

6.1.6 Wastewater

Wastewater		
Item or Feature	**Observed**	**REC**
Wastewater treatment systems and/or water treatment systems	No	
Oil/water separators	No	
Other	No	

Domestic wastewater generated at the subject property is disposed by means of the sanitary sewer system. No industrial process is currently performed at the subject property.

6.1.7 Lead in Drinking Water

According to available information, a public water system operated by the Kaukauna Utilities Department (KUD) serves the subject property vicinity. According to a representative of the KUD, shallow groundwater beneath the subject property is not utilized for domestic purposes. The sources of public water for the City of Kaukauna is groundwater from five groundwater wells that are located through the city. The depths of the wells range from 500- to 850-feet below ground surface. According to the City of Kaukauna and the 2017 Annual Water Quality Report, water supplied to the subject property is in compliance with all State and Federal regulations pertaining to drinking water standards, including lead and copper. Water sampling was not conducted to verify water quality.

6.1.8 Additional Site Observations

No additional general site characteristics were observed.

6.2 Potential Environmental Hazards

6.2.1 Hazardous Materials and Petroleum Products Used or Stored at the Site

Hazardous Substances and/or Petroleum Products Noted Onsite		
Item or Feature	**Observed**	**REC**
Drums, Barrels, and/or Containers >5 gallons	No	
Parts Washer	No	
MSDS	No	
Other	No	

No hazardous substances or petroleum products were observed on the subject property during the site reconnaissance.

6.2.2 Aboveground & Underground Hazardous Substance or Petroleum Product Storage Tanks (ASTs/USTs)

AST and UST Hazardous Substance or Petroleum Product Storage Tanks		
Item or Feature	**Observed**	**REC**
ASTs	No	
USTs	No	
Other	No	

No evidence of current or former ASTs or USTs was observed during the site reconnaissance.

6.2.3 Evidence of Releases

Evidence of Releases		
Item or Feature	**Observed**	**REC**
Stained Soil	No	
Stained Pavement or Similar Surface	No	
Surface Water Discoloration, Odor, Sheen, and/or Free Floating Product	No	
Other	No	

No spills, stains or other indications that a surficial release has occurred at the subject property were observed.

6.2.4 Polychlorinated Biphenyls (PCBs)

PCBs		
Item or Feature	**Observed**	**REC**
Pole or Pad-Mounted Transformers and/or Capacitors	No	
Hydraulic Lifts	No	
Elevators	No	

PCBs		
Item or Feature	**Observed**	**REC**
Compactors/Balers	No	
Other	No	

No potential PCB-containing equipment (transformers (labeled as non-PCB containing), oil-filled switches, hoists, lifts, dock levelers, hydraulic elevators, etc) was observed on the subject property during Partner's reconnaissance.

6.2.5 Strong, Pungent or Noxious Odors

Strong, Pungent, or Noxious Odors		
Item or Feature	**Observed**	**REC**
Odors	No	
Other	No	

No strong, pungent or noxious odors were evident during the site reconnaissance.

6.2.6 Pools of Liquid

Pools of Liquid		
Item or Feature	**Observed**	**REC**
Pools of Liquids	No	
Other	No	

No pools of liquid were observed on the subject property during the site reconnaissance.

6.2.7 Drains, Sumps and Clarifiers

Drains, Sumps, and Clarifiers		
Item or Feature	**Observed**	**REC**
Interior Floor Drains	No	
Sumps, Cisterns, Catch Basins, and/or Dry Wells	No	
Grease Traps	No	
Oil/Water Separator	No	
Other	No	

No drains, sumps, or clarifiers, other than those associated with storm water removal, were observed on the subject property during the site reconnaissance.

6.2.8 Stressed Vegetation

Stressed Vegetation		
Item or Feature	**Observed**	**REC**
Stressed Vegetation	No	
Other	No	

No stressed vegetation was observed on the subject property.

6.2.9 Additional Potential Environmental Hazards

Additional Potential Environmental Hazards		
Item or Feature	**Observed**	**REC**
Dry Cleaning	No	
Photo Processing	No	
Laboratory Hoods and/or Incinerators	No	
Radiological Hazards (does not include radon)	No	
Other	No	

No additional environmental hazards, including landfill activities or radiological hazards, were observed.

6.2.10 Mold (Non-ASTM Item)

Molds are microscopic organisms found virtually everywhere, indoors and outdoors. Mold will grow and multiply under the right conditions, needing only sufficient moisture (e.g.in the form of very high humidity, condensation, or water from a leaking pipe, etc.) and organic material (e.g., ceiling tile, drywall, paper, or natural fiber carpet padding).

Partner observed accessible, interior areas for the subject property buildings for significant evidence of mold growth with the exceptions detailed in Section 1.5 of this report; however, this ESA should not be used as a mold survey or inspection. Additionally, this limited assessment was not designed to assess all areas of potential mold growth that may be affected by mold growth on the subject property. Rather, it is intended to give the client an indication as to whether or not conspicuous (based on observed areas) mold growth is present at the subject property. This evaluation did not include a review of pipe chases, mechanical systems, or areas behind enclosed walls and ceilings.

No obvious indications of water damage or mold growth were observed during Partner's visual assessment.

6.3 Adjacent Property Reconnaissance

The adjacent property reconnaissance consisted of observing the adjacent properties from the subject property premises. No items of environmental concern were identified on the adjacent properties during the site inspection, including hazardous materials, petroleum products, ASTs, USTs, evidence of releases, PCBs, strong or noxious odors, pools of liquids, sumps or clarifiers, pits or lagoons, stressed vegetation, or other potential environmental hazards.

7.0 HUD HEROS / COMPLIANCE ITEMS

HUD has established the HUD Environmental Review Online System (HEROS) – Form HUD 4128 to document the environmental review process, "Environmental Assessment and Compliance Finding for Related Laws", with NEPA and other environmental Federal laws, authorities, Executive Orders, and HUD standards, outlined within the Multifamily Accelerated Processing (MAP) Guide dated January 29, 2016 (Effective Date May 28, 2016).

This section is outlined within the *HUD Part 50 – Environmental Assessment Form* and *HUD Partner Worksheets* along with supporting documentation. This worksheet information noted below is provided under a separate cover that is included concurrent with this Phase I ESA.

- Air Quality
- Airport Hazards
- Coastal Barrier/Management Zone
- Endangered or Threatened Species or Habitats
- Environmental Assessment Factors and Analysis
- Environmental Justice
- Environmental Review Housing Requirements (Lead-Based Paint, Radon, Asbestos, Additional Nuisances and Hazards)
- Environmental Review Project Information
- Farmland Protection
- Flood Insurance
- Flood Management
- Hazardous Industrial Operations
- Noise Compliance
- Sole Source Aquifer
- State Historic Preservation Office (SHPO)
- Toxic Chemical and Radioactive Materials, Including VES
- Wetland
- Wild and Scenic Rivers

8.0 FINDINGS AND CONCLUSIONS

Findings – ASTM Items

A *recognized environmental condition (REC)* refers to the presence or likely presence of any hazardous substances or petroleum products in, on, or at a property: due to release to the environment; under conditions indicative of a release to the environment; or under conditions that pose a material threat of a future release to the environment.

- The west adjacent property, identified as the USACE – Parcel J (Kaukauna Power Canal) is an open Environmental Repair Program (ERP) case on the online Wisconsin Bureau for Redevelopment and Remediation Tracking (WI BRRTS) database. The site's address is identified as the "end of 420 Bicentennial Court". The responsible party for this site is listed at the United States Army Corps of Engineers (USACE). According to Wisconsin Department of Natural Resources (WI DNR) records, the constituent of concern for this site is identified as lead and impacts are known to be present in the soil media. The case was opened and responsible party notified on March 1, 2003. To date, no remedial activities have occurred. Per correspondence with the WI DNR case manager assigned to site, the USACE has not made efforts to pursue remediation of the site. Parcel J, as depicted on a sampling map obtained from the WI DNR, encompasses the shoreline of the Fox River beginning to the west of the subject property and extends eastward toward the subject property, ultimately concluding at the northeast corner of the subject property. In total, this site represents the north and northwest adjacent property. Soil sampling results from 2004 and 2005 subsurface investigation indicate elevated levels of lead immediately north and northwest of the subject property boundary along the Fox River shoreline.

  Limited information is available for the USACE – Parcel J site given the USACE's denial of responsibility for the contamination to date. Correspondence with WI DNR also indicated the site's priority level with the WI DNR does not qualify it for State funded remediation. As of the August 9, 2016 semi-annual status report, no action has been taken at the site. The WI DNR will continue to issue semi-annual status updates per WI DNR policy, however, at this time, no action is anticipated.

  Based on the known soil contamination abutting the northern and northwestern boundary of the subject property, this site represents a *recognized environmental condition (REC)* at the subject property.

A *controlled recognized environmental condition (CREC)* refers to a REC resulting from a past release of hazardous substances or petroleum products that has been addressed to the satisfaction of the applicable regulatory authority, with hazardous substances or petroleum products allowed to remain in place subject to the implementation of required controls. The following was identified during the course of this assessment:

- The property, identified as Ghost Town Fitness Center at 180 Fox Shores Drive, is located adjacent to the east of the subject property. This site is registered as an WI ERP site which originates from its listing on the WI DNR Environmental Cleanup and Brownfields Redevelopment (BRRTS)

database. According to the EDR regulatory database and WI DNR files, groundwater contamination was identified at this property. Substances identified exceeding regulatory reporting thresholds are listed as arsenic and selenium. The substances were identified through subsurface testing that occurred in 2006. An excerpt of the discussion from the limited subsurface investigation is provided below:

- *The NR 140 Permissible Allowable Limit (PAL) for arsenic is 1 microgram (µ) per liter. Arsenic was detected at a concentration of 7.8 micrograms per liter (µg/L) in the groundwater sample collected during the July 26, 2006 push-probe assessment and was detected at a concentration of 3.0 µg/L in the groundwater sample collected from the monitoring well on September 12, 2006. The NR 140 PAL for selenium is 10 µg/L. Selenium was detected at a concentration of 32 µg/L in the groundwater sample collected during the July 26, 2006 push-probe assessment and was detected at a concentration of 14.7 µg/L in the groundwater sample collected from the monitoring well on September 12, 2006. Lead was detected at a concentration of 5.8 µg/L during the July 26, 2006 push-probe assessment but was not detected in the groundwater sample collected from the monitoring well on September 12, 2006.*

Findings of the limited subsurface investigation were submitted to the WI DNR, along with the required documentation to obtain a closure letter from the State. Upon review of the limited subsurface investigation, the WI DNR granted closure to the site pursuant to an exemption to a PAL for a substance of public health concern (*Wisconsin Administrative Code s. NR 140.28(2)(b)*) given the following criteria were met at the site:

5. The measured or anticipated increase in the concentration of the substance will be minimized to the extent technically feasible and economically feasible;
6. Compliance with the PAL is either not technically or economically feasible;
7. The enforcement standard for the substance will not be attained or exceeded at the point of standards application; and
8. Any existing or projected increase in the concentration of the substance above the background concentration does not present a threat to public health or welfare.

Per a WI DNR *No Further Action Letter*, dated October 9, 2006, this case was granted closure with no further investigation, remediation or other action required at this site. The WI DNR granted closure to the site as the constituent levels of arsenic and selenium at the site were remediated to WI DNR standards in accordance with *Wisconsin Administrative Code s. NR 726.05*.

Based on the case closure and direction of groundwater flow identified through subsurface investigation, this site represents a *controlled recognized environmental condition (CREC)*.

- The property, identified as the Kaukauna Waste Oil Collection Site at 201 West 2nd Street, 222 3rd Street, and 3rd Street 200 Block, and is located adjacent to the south of the subject property beyond Bicentennial Court. This site reported a release of petroleum based fuels *circa 1993*,

which reportedly impacted soil and groundwater. The release occurred as a result of leaking UST and was reported to the WI DNR on December 28, 1993. The responsible party for the release, contamination and remediation is identified as the City of Kaukauna – Public Works Department. Remedial efforts at the subject property include soil excavation and the removal of two, 10,000-gallon USTs and one, 550-gallon waste oil UST. Regulatory documents obtained from the WI DNR indicate soil excavations around tank pits at ranging between 4' and 13' below ground surface. Groundwater gradient maps indicate groundwater flow to the east-southeast, away from the subject property.

As a result of the known contamination, soil and groundwater deed restrictions were placed on the property as indicated on the *Deed Restriction* recording document dated May 20, 2003. The Deed Restriction document states that natural attenuation has been approved by the WI DNR to remediate groundwater contamination exceeding *ch. NR 140 of the Wisconsin Administrative Code* for groundwater standards within the boundary of the deed-restricted property. Given the implementation of the Deed Restriction, further groundwater and soil remediation activities are considered unnecessary.

The responsible party submitted all required documentation pursuant to receiving a Final Case Closure letter from the WI DNR. As stated by the WI DNR, the responsible party complied with the conditions for closure, including submittal of the Deed Restriction, and as such, the WI DNR concluded, "Based on the correspondence and data provided, it appears that your case meets the screening criteria of s. *NR 746.07*, and the requirements of *ch. NR 726* of the Wisconsin Administrative Code. The Department considers this case closed and no further investigation, remediation or other action is required at this time."

Based on the case closure and the groundwater Deed Restriction, this site represents a *controlled recognized environmental condition (CREC)*

A *historical recognized environmental condition (HREC)* refers to a past release of any hazardous substances or petroleum products that has occurred in connection with the property and has been addressed to the satisfaction of the applicable regulatory authority or meeting unrestricted use criteria established by a regulatory authority, without subjecting the property to any required controls. The following was identified during the course of this assessment:

- Partner did not identify historical recognized environmental conditions during the course of this assessment.

An *environmental issue* (also referred to as *Business Environmental Risk*) refers to environmental concerns identified by Partner, which do not qualify as RECs; however, warrant further discussion. The following was identified during the course of this assessment:

- Partner did not identify environmental issues during the course of this assessment.

Conclusions, Opinions and Recommendations

Partner has performed a Phase I Environmental Site Assessment in conformance with the scope and limitations of ASTM Standard Practice E1527-13 of 400 Fox Shores Drive in the City of Kaukauna, Outagamie County, Wisconsin (the "subject property"). Any exceptions to or deletions from this practice are described in Section 1.5 of this report.

This assessment has revealed evidence of recognized environmental conditions and/or environmental issues in connection with the subject property. Based on the conclusions of this assessment, Partner recommends the following:

- Given the known contamination of the surrounding properties as described in Section 4.2.2, a limited subsurface investigation should be conducted in order to evaluate the presence or absence of soil and/or groundwater contamination due at the subject property to the historical use of the subject property. Compliance with HUD MAP Guidelines, specifically Section 9.3, *Contamination Analysis,* will be addressed during and upon completion of the limited subsurface investigation.

9.0 SIGNATURES OF ENVIRONMENTAL PROFESSIONALS

Partner has performed a Phase I Environmental Site Assessment of the property located at 400 Fox Shores Drive in the City of Kaukauna, Outagamie County, Wisconsin in conformance with the scope and limitations of the protocol and the limitations stated earlier in this report. Exceptions to or deletions from this protocol are discussed earlier in this report.

By signing below, Partner declares that, to the best of our professional knowledge and belief, the undersigned meet the definition of an *Environmental Professional* as defined in §312.10 of 40 CFR 312 and have the specific qualifications based on education, training, and experience to assess a *property* of the nature, history, and setting of the subject *property*. Partner has developed and performed the all appropriate inquiries in conformance with the standards and practices set forth in 40 CFR Part 312.

I understand that my Environmental Site Assessment (ESA) will be used by Berkadia Commercial Mortgage LLC to document to the U.S. Department of Housing and Urban Development that the MAP Lender's application for FHA multifamily mortgage insurance was prepared and reviewed in accordance with HUD requirements. I certify that my review was in accordance with the HUD requirements applicable on the date of my review and that I have no financial interest or family relationship with the officers, directors, stockholders, members or partners of the lender or affiliated entities, Borrower or affiliated entities, the general contractor, any subcontractors, the buyer or seller of the proposed property or engage in any business that might present a conflict of interest.

I hereby certify under penalty of perjury that all of the information I have provided on this form and in any accompanying documentation is true and accurate. I acknowledge that if I knowingly have made any false, fictitious, or fraudulent statement, representation, or certification on this form or on any accompanying documents, I may be subject to criminal, civil, and/or administrative sanctions, including fines, penalties, and/or imprisonment under applicable federal law, including but not limited to 12 U.S.C. § 1833a; 18 U.S.C. §§1001, 1006, 1010, 1012, and 1014; 12 U.S.C. §1708 and 1735f-14; and 31 U.S.C. §§3729 and 3802.

EXECUTIVE SUMMARY

DESCRIPTION

Environmental Data Resources, Inc.'s (EDR) City Directory Report is a screening tool designed to assist environmental professionals in evaluating potential liability on a target property resulting from past activities. EDR's City Directory Report includes a search of available city directory data at 5 year intervals.

RECORD SOURCES

EDR's Digital Archive combines historical directory listings from sources such as Cole Information and Dun & Bradstreet. These standard sources of property information complement and enhance each other to provide a more comprehensive report.

EDR is licensed to reproduce certain City Directory works by the copyright holders of those works. The purchaser of this EDR City Directory Report may include it in report(s) delivered to a customer. Reproduction of City Directories without permission of the publisher or licensed vendor may be a violation of copyright.

5 Sensational Reasons to call your

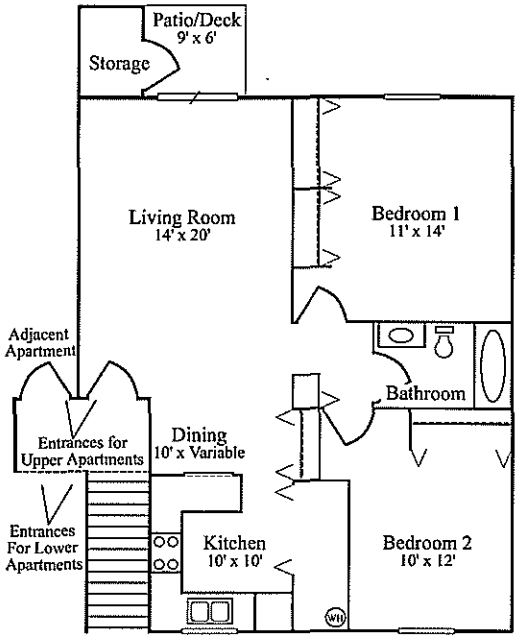
1.

Surrounded by Beauty

Enjoy calming waters and the beautiful shores of the Fox River every season of the year from our riverside benches. Bordered by the beautiful Fox River, Fox Shores Apartments is located seconds from downtown Kaukauna and within easy walking distance from the beauty and serenity of Riverside Park, LaFollette Park, Central Park and Thousand Islands Nature Preserve.

2.

Spacious, Modern Apartments



Fox Shores Apartments can provide you with all the features you require for easy, carefree living. Each apartment includes a spacious, well designed floor plan with two large bedrooms, a contemporary kitchen open to the dining area, open to a spacious living room, open to the patio with a beautiful view.

Because our units **are not** back to back, enjoy the benefits of having windows on both sides of your apartment and the security of a private entrance. Conveniences include storage closets, air conditioning, garbage disposals, window treatments, cable in both bedrooms and the living room, ceiling fans, laundry hookups (laundry included in some), and dishwashers in most.

3.

Professionally Managed

The Fox Shores Apartments management team knows that excellent customer service is both our mission and our goal. We're sure you'll find our courteous staff friendly and helpful. Professional maintenance is provided within 48 hours. Most times, maintenance is done within 24 hours! We are also available to handle any emergency 24 hours a day, 7 days a week.

4.

Amenities Galore

Garages are included with on-water apartments and optional for off-water apartments, but you won't have to use your car to find things to do. Fox Shores residents have easy access to the adjacent Ghost Town Fitness Center. And after a hardy workout, many places to dine are only a short walk away. After dining, relax in the many parks surrounding our community or just relax and fish at our very own parklike river's edge.

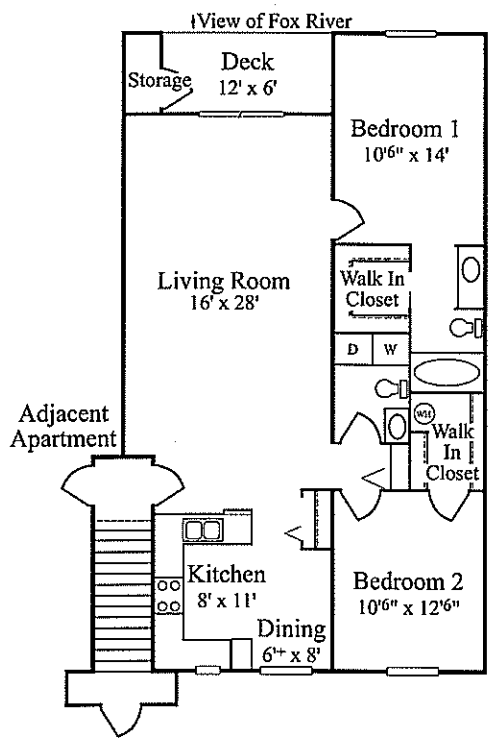
5.

The Rest of the Story

With all that Fox Shores has to offer, calling your new home Fox Shores Apartments is a wise choice. Each Fox Shores apartment, as well as the community itself, was designed with your convenience and comfort in mind. Here is the rest of the story...

new home Fox Shores Apartments

- Excellent location
- Spacious, well designed floor plan with two bedrooms
- Windows on both sides of your apartment
- Inexpensive Kaukauna Electric electricity
- Linen closet
- Patio or balcony with storage closet
- Contemporary kitchen
- Blinds throughout
- Dining room ceiling fan
- Smoke alarms—hard wired (batteryless)
- Phone jacks in bedrooms, kitchen and living room
- Air conditioning
- Cats allowed with some restrictions
- Assigned parking
- Adjacent Ghost Town Fitness Center
- Fish only a cast away
- Parklike area along our own shores
- Professional owner management with friendly, helpful staff
- Lawn care and snow removal
- Prompt, trained maintenance crew with 24 hour emergency service
- Fun, year round activities with residents



Off Water Apartments also include:

- Large bathroom
- Some with dishwashers
- Optional garage
- Private entries
- Laundry hookups

On Water Apartments also include:

- Dishwashers
- Garages
- Private and almost private entries
- Walk-in closets
- Laundry in most
- Second bath, half or full

Overview

Property Name	Fox Shores Apartments
Property Address	400 Fox Shores Drive, Kaukauna, WI 54915
Building Area	Approximately 80,000 Square Feet (SF)
Units	56
Property Area	Approximately 2.815 acres
Year Built	1983-1992
Current Use	Multi-Family Residential
Historical Use	Rail Yard
Known Release	None
Suspected Release	None
Regulatory Records	No Regulatory Records were identified for the subject Property.
AULs	No Activity and Use Limitations were identified.
Engineering Controls	No Engineering Controls were identified.
Environmental Liens	Research of Environmental Liens was beyond the scope of this Assessment.

Conclusions	**Summary**	**Action Recommended?**	**Cost**
REC	None	None	$0
HREC	Prior use of subject property and surrounding properties as a railyard and railroad roundhouse. Groundwater testing confirmed that any contamination present is below applicable action levels.	None	$0
Opinion	Identified conditions do not indicate environmental impact to the Property.	None	$0
Data Gaps	No data gaps were identified which would be likely to impact our conclusions.	None	$0

ADDITIONAL SERVICES			
Issue	**Summary**	**Action Recommended?**	**Cost**
Asbestos	No friable or damaged suspect ACM observed.	None	$0
Lead-Based Paint	Based on age, LBP is not a concern.	None	$0
Drinking Water	No concerns identified.	None	$0
Radon	No concerns identified.	None	$0
Mold	No concerns identified.	None	$0
Wetlands	No concerns identified.	None	$0
Indoor Air Quality	No concerns identified.	None	$0
Compliance	No concerns identified.	None	$0

Data Gaps

No significant data gaps were encountered during completion of this assessment. Data gaps occur when, despite good faith efforts, the consultant is unable to identify information required to satisfy objectives of the assessment. Data gaps may result from incompleteness in any of the activities required by the ESA Standard, or by limiting conditions encountered during completion of the work. The ESA Standard requires that data gaps be identified in the report when they significantly impact the ability of the consultant to identify Recognized Environmental Conditions at the Property. Limiting Conditions identified in this report are not considered to significantly impact our ability to satisfy the objectives of this assessment.

Limiting Conditions

GRS Group encountered the following limiting conditions in completion of the work:

- Observation of the living units was contractually limited to 10% of those present. Unidentified conditions may exist in units not observed.

- Our view of the ground surface was partially obstructed by snow cover and the presence of parked automobiles. This circumstance was limited in extent. Some conditions may have been concealed at the time of our assessment, however the extent of those conditions is likely to be minimal and no additional action is recommended at this time.

Findings and Opinions

No RECs were identified as a result of our assessment. The Property is currently used for multi-family residential purposes. No activities involving the use, storage, treatment, disposal or emission of hazardous materials are known to occur on-site.

Current subject property improvements consist of six two-story apartment building containing 56 living units totaling approximately 80,000 Gross Square Feet (GSF) . Additional improvements include four garage buildings, cast in place concrete sidewalks, asphalt paved driveways and parking areas, and landscaped areas.

Prior to the development of the current improvements between 1983 and 1992, the subject property was utilized as a railroad yard, and was historically improved with structures identified as the Chicago & Northwestern Railway Shops, including a Kimberly-Clark Paper Mill warehouse, a small warehouse, a blacksmith shop and a supply shed. No other features of environmental concern are located at the Property. No historical activities suspected of involving the use, storage, treatment, disposal or emission of hazardous materials, were identified during this assessment. The subject property was not identified on any of the environmental agency databases reviewed in association with its former usage.

The adjoining property to the east, currently Ghost-Town Fitness Center, is included on the WI ERP database. The inclusion is due to this site's prior use as a railroad roundhouse. According to a Limited Site Assessment of the site, groundwater was tested in an area that would be considered centrally located on the railyard. The sample collected was found to be below applicable action levels for Volatile Organic Compounds (VOCs), Diesel Range Organics (DRO), and RCRA metals. The database indicates that the Wisconsin Department of Natural Resources (WDNR) closed this WI ERP site on October 9, 2006. Therefore, the historical use of the adjoining property as a railyard and roundhouse is considered an off-site Historical REC (HREC) for which no further actions are required.

Additionally, eighteen (18) LUST sites and six (6) UST sites were identified within the study radii. Seventeen (17) of the identified LUST sites have been closed by the WDNR, indicating that no further actions are required. Therefore, these LUST sites are not considered RECs. The remaining open site, identified as City of Kaukauna Property, is located approximately 0.19 mile to the southeast, and potentially up-gradient of the subject property. This site is also known as the former Gunderson's Cleaners. According to the EDR report, all of the USTs at this have been abandoned in place or removed from the ground. Ongoing remedial activities have been performed at the site since 2002 and currently include groundwater monitoring. Numerous Site Assessment Grants (SAG) have been awarded to cover the costs accociated with the remedial activities at this site. Based on the remedial actions taken at this site, and the results of the recent groundwater sampling performed in the immediate vicinity of the subject property, this site is not considered an REC.

Conclusions

Recognized Environmental Conditions

A Recognized Environmental Condition (REC) is identified when the Assessment finds the presence or likely presence of any hazardous substances or petroleum products on a property under conditions that indicate an existing release, a past release, or a material threat of a release of any hazardous substances or petroleum products into structures on the property or into the ground, ground water, or surface water of the property.

We have performed a Phase I Environmental Site Assessment in conformance with the scope and limitations of ASTM Practice E 1527-05 of 400 Fox Shore Drive in Kaukauna, WI (the Property). Any exceptions to or deletions from this practice are described in Section 1.7 of this report. This assessment has revealed no evidence of RECs in connection with the Property.

On-Site Recognized Environmental Conditions

No Recognized Environmental Conditions were identified as a result of on-site activities or conditions.

Off-site Recognized Environmental Conditions

No Recognized Environmental Conditions were identified as a result of activities or conditions at nearby properties.

Historical Recognized Environmental Conditions

On-Site Historical Recognized Environmental Conditions

Historical Recognized Environmental Conditions were identified as a result of on-site activities or conditions as follows:

- The prior use history of the subject property as a railroad yard is considered an HREC.

Off-site Historical Recognized Environmental Conditions

Historical Recognized Environmental Conditions were identified as a result of activities or conditions at nearby properties as follows:

- The prior use history of the adjoining property to the east as a railroad yard and roundhouse is considered an HREC.

De Minimis Environmental Conditions

De minimis environmental conditions indicate a release which generally would not represent a threat to human health and would generally not be the subject of an enforcement action if brought to the attention of appropriate governmental agencies.

No de minimis environmental conditions were identified as a result of activities or conditions at the subject or nearby properties.

Additional Services

Additional services were provided to evaluate the presence of asbestos containing materials (ACMs), radon, lead-based paint, lead in drinking water, mold, indoor air quality, wetlands and compliance. No evidence of related conditions of concern was identified during completion of the Assessment.

Recommendations

No addition action or assessment is recommended as a result of this Assessment.

1.0 Introduction

This Phase I Environmental Site Assessment was performed by Global Realty Services Group (GRS Group) for Alliant Capital, LLC, and was prepared by Andy Bryan, one of GRS Group's Field Professionals and was reviewed by one of our senior reviewers, Anthony Mueller.

1.1 Purpose and Use

This assessment along with findings, conclusions and recommendations (collectively, the Assessment) is intended to support evaluation of the property by our Client prior to acceptance of the Property as collateral to support a real estate secured loan. Global has performed the agreed services in order to identify Recognized Environmental Conditions (RECs); the presence or likely presence of any hazardous substances or petroleum products on a property under conditions that indicate an existing release, a past release, or a material threat of a release of any hazardous substances or petroleum products into structures on the property or into the ground, ground water, or surface water of the property. The supporting work was not intended to be exhaustive or to guarantee of the identification of every possible issue of potential concern, and may not be construed as a warranty or guarantee of any kind.

Unless expressly identified herein, all opinions, conclusions, and recommendations provided presume that the property occupancy and use will remain as observed at the time of our site reconnaissance and that no significant renovation, subdivision, conversion to condominiums or similar change will occur. This report will be invalidated in the event of such activities.

This report is the intellectual property of Global Realty Services, Global, and may not be used without Global's express written authorization. Unauthorized use of this report is a violation of Global's legal rights. Any unauthorized user of this report shall be subject to civil and criminal penalties and shall be responsible to indemnify, defend and hold Global harmless from any and all losses, damages and claims arising, in any part, from such use.

1.2 Scope of Assessment

This assessment was conducted in accordance with an agreement governing the nature, scope intent and purpose of the work and in general accordance with ASTM E 1527-05, Standard Practice for Environmental Site Assessments: Phase I Environmental Site Assessment Process, the ESA Standard and any additional requirements identified in the agreement under which the work was performed.

Since GRS Group's responsibilities are limited by the agreed scope of work, an understanding of activities not included within that scope of work is important to proper use of the information contained in this Report. Some clarification of the work performed is provided below, but a more complete list of inherent limitations is provided at Appendix C.

- No environmental site assessment can wholly eliminate uncertainty regarding the potential for recognized environmental conditions in connection with a property. The ESA Standard identifies a balance between competing goals to reduce uncertainties within reasonable constraints of time and cost, and this assessment is intended to reduce, but not eliminate, uncertainty regarding the potential for recognized environmental conditions in connection with a property within reasonable limits of time and cost. The reader should be thoroughly familiar with the ESA Standard in order to assure an appropriate understanding of limitations inherent in the agreed scope of services.

- In some cases conditions encountered during completion of the Assessment, for example limited access portions of the Property, can influence our ability to fulfill the objectives of

the assessment. Where applicable, such limiting conditions are identified later in this section of the report. Also, certain work is specifically excluded by the ESA Standard. Unless the expressly identified in the agreed proposal for services, all tasks identified by the ESA Standard as "Non-Scope Considerations" are excluded from this Assessment.

- Reconnaissance conducted during this assessment was limited to accessible areas of the property and specific areas identified in this Report. Accordingly, conditions may exist which were not identified as a result of our assessment and which may impact our conclusions concerning the condition of the Property. Any conditions known or discovered which were not identified during the completion of this assessment should be reported to GRS Group upon discovery and may impact the conclusions and recommendations of this Report.

- When provided by the client, GRS Group has considered "User Provided Information" in completion of this Assessment; however GRS Group has no control over such information and cannot guarantee the User's satisfaction of requirements for All Appropriate inquiry.

- Limited information concerning regulatory compliance was utilized in preparation of this Assessment; however the work is not intended as a compliance audit and may not be relied upon or utilized as evidence regulatory compliance.

1.3 Additional Services

The presence of 'environmental' conditions such as the asbestos containing materials, lead-based paint, lead in drinking water, indoor air quality (including vapor intrusion), wetlands, mold, endangered species, elevated radon concentrations and compliance, among others, can result in liabilities for property owners and disrupt planned operations or cash flow and is generally beyond the scope of a Phase I assessment as defined by the ESA standard. The following additional services have been performed at the request of our Client. All work described is in the context of and subject to the principles underlying the ESA Standard. A more complete description of specific actions taken to address these concerns is included in the report along with a summary of our related findings.

Recommendations

The ESA Standard requires the consultant to provide recommendations when the consultant is unable to obtain information which they would expect to significantly impact their ability to identify recognized environmental conditions. Many clients also look to the consultant for recommendations to address business risks. This can be problematic since the reason for engaging the assessment and risk appetite can vary significantly from client to client. Some clients are primarily concerned with the identification of direct evidence of a release, while others are concerned to understand every possibility of a release. This distinction can significantly impact the consultant's recommendations. In simplified form, the ESA Standard defines a recognized environmental condition as the likely release of hazardous substances. A recognized environmental condition is neither restricted to known releases nor intended to include any possibility of a release. Unless otherwise requested by the client, our report will include recommendations as required by the ESA Standard along with our opinion of additional assessment necessary to assess the significant release or likely release of a hazardous substance or petroleum product at the property. The Client should carefully review and consider all recommendations to assure an understanding of the underlying concerns and verify that any recommendations are consistent with their unique appetite for risk.

Asbestos Containing Building Materials

During completion of the site reconnaissance, Global looked for building materials commonly believed to contain asbestos. This assessment provides a screening for the presence of

asbestos containing materials to assist in understanding of business risks associated with the property, but is not intended and may not be used for the satisfaction of regulatory requirements and is not a suitable replacement for pre-demolition or other more in-depth studies.

Radon

Global has reviewed Radon maps and other necessary and readily available information concerning average radon concentrations in the area of the property. Site-specific sampling was completed to verify radon concentrations at the Property.

Lead-Based Paint

During completion of the site reconnaissance, Global looked for finished surfaces to which lead-based paint (LBP) is commonly applied. This assessment provides a screening for the presence of lead-based paint to assist in understanding of business risks associated with the property, but is not intended and may not be used for satisfaction of regulatory requirements and is not a suitable replacement for pre-demolition or other more in-depth studies.

Mold

Material and readily apparent evidence of the presence of mold which is identified during completion of the Assessment is described in the report.

Drinking Water

Global contacted the drinking water supplier to obtain information concerning compliance with applicable Federal regulations.

Indoor Air Quality

This assessment includes an interview with the Key Site Manager to obtain information concerning existing indoor air quality complaints, and, when soil or groundwater contamination is known to have affected the Property, a Tier 1 evaluation of the potential for vapor intrusion, in accordance with the applicable ASTM standard.

Wetlands

The National Wetlands Inventory has been reviewed to assess the presence of wetlands at the Property.

Compliance

Material regulatory requirements governing environmentally sensitive operations and conditions at the Property will be identified and Global will interview the Key Site Manager to assess compliance. No full compliance audit, or review of supporting documentation or regulatory files has been conducted.

1.4 Reliance

RESTRICTED USE AND RELIANCE - THIS REPORT WAS PREPARED BY GLOBAL REALTY SERVICES FOR THE SOLE USE AND BENEFIT OF OUR CLIENT AND THE FEDERAL NATIONAL MORTGAGE ASSOCIATION (FANNIE MAE) IN ACCORDANCE WITH THE PROVISIONS OF OUR CONTRACT AND MAY NOT BE USED OR RELIED UPON BY ANY OTHER PARTY WITHOUT THE EXPRESS WRITTEN CONSENT OF GLOBAL REALTY SERVICES.

1.5 Methodology

Recognized Environmental Condition

Criteria for the identification of Recognized Environmental Conditions vary substantially across the industry. Some Environmental Professionals identify Recognized Environmental Conditions whenever there is a possibility of impact to a property, while others recognize Recognized Environmental Conditions only when presented with direct evidence that a release has occurred. The ESA Standard defines a REC in terms of the "presence or likely presence" of hazardous materials under conditions that indicate an existing, past, or threatened release. By this definition the mere possibility of a release fails to fulfill the definition of a REC. A requirement for the discovery of direct evidence before identification of a REC is equally unsupportable. GRS Group considers both the known and likely presence and release of hazardous materials in identifying Recognized Environmental Conditions.

Historical Recognized Environmental Condition

The ESA Standard allows for reclassification of RECs as Historical Recognized Environmental Conditions. By example, the ESA Standard cites a situation in which a release was identified, cleanup has occurred and regulatory approval of cleanup operations has been granted, though the ESA Standard is careful to leave the final determination of HREC status to the discretion of the environmental professional. It is also possible to reclassify a REC when additional assessment reveals no evidence of a release. Since the definition of a REC requires the presence or likely presence of a release, the demonstration that no release has occurred would expunge the initial classification.

1.6 Terminology

Hazardous Material - The ESA Standard defines the terms *hazardous substance* and petroleum products, however the terms are often used in conjunction, resulting in an awkward phrase where a simpler term would be desirable. The term hazardous material is used in this report to include both hazardous substances and petroleum products as those terms are defined by the ESA Standard.

Material Threat of a Release - There is sometimes confusion regarding the meaning of the phrase "material threat of release." A *material threat* is defined within the context of the ESA Standard as "a physically observable or obvious threat which is reasonably likely to lead to a release..." The material threat of a release is used in consideration of the likelihood of a future release and has no application in consideration of an historical release.

1.7 Deviations

The ESA Standard characterizes issues which are beyond the scope of assessment as Non-Scope Considerations. Any inclusion of these issues or considerations in this assessment is described earlier in this Section: Scope of Assessment. Inclusion of this work is limited to the scope identified in the agreement under which the work was performed, is subject to underlying principles and limitations of the ESA Standard, and shall not be construed as evidence of a responsibility to evaluate other such issues or considerations.

1.8 Special Terms and Conditions

This Assessment has been performed in accordance with an agreement governing the nature, scope, extent and purpose of the work. Any conflicting provisions of that agreement supersede the provisions of other requirements referenced herein.

2.0 Property Description

The subject property consists of a rectangular-shaped parcel of land totaling approximately 2.815 acres. It is improved with six (6) two-story apartment buildings totaling approximately 80,000 GSF and containing 56 living units. The buildings, which were constructed between 1983 and 1992, are of wood-frame construction with exterior walls consisting of brick veneer facades with wood trim or vinyl siding. All of the buildings are provided with pitched asphalt composition shingled roofs. Additional improvements include four garage buildings, concrete sidewalks, asphalt-paved driveways and parking areas, and landscaped areas.

Property Name	Fox Shores Apartments
Property Address	400 Fox Shores Drive, Kaukauna, WI 54915
Building Area	Approximately 80,000 Square Feet (SF)
Property Area	Approximately 2.815 acres
Year Built	1983-1992
Current Use	Multi-Family Residential
Number of Buildings	26
Access	Driveways off of Lynndale Avenue to the west, Pershing Street to the north, and Glendale Avenue to the south.

2.1 Legal Description

Parcel 323-0408-00: CSM 59 LOT 3 LESS 961R345 LESSCSM 307, CSM 348, 5056M10
Parcel 323-0408-01: COM SE COR LT 1 CSM 155 N10D E43.02FT TO POB N10D E203.23FTS79D E104.54FT S54D E110FT S35D W225.23FT TO ST N 55D W76.22FT N57D W40.80FT TO POB ALSO D ESC AS LOT 1 CSM VOL 2 PG 307 .83AC

Parcel 323-0408-02: CSM 307 LOT 2 (PLATTED OUT OF PRT LOT 1 CSM 59) .83AC M/L #1256329

2.2 Reconciliation of Property Data

Improvements observed at the property are consistent with information provided at the time of our engagement. No significant deviations were identified.

2.3 Site and Vicinity General Characteristics

The property is located in a mixed use residential and commercial area. The terrain is generally level. The Fox River is located along the northern boundary of the subject property.

2.4 Current Use

No environmentally sensitive activities are conducted at the property. The property is used for multi-family residential purposes.

2.5 Description of Improvements

DESCRIPTION OF IMPROVEMENTS	
Building	Six 2-story apartment buildings
Construction	Type II - Non-rated. The buildings are constructed of CMU load-bearing walls and interior wood framing.
Exterior Finishes	Brick veneer or vinyl siding
Interior Finishes	Painted drywall walls and ceilings

Parking	Surface parking and four garage buildings are provided on-site.
Amenities	None
Heating Fuel	Natural gas
Source of Drinking Water	Municipal (City of Kaukauna)
Waste Water Disposal	Municipal (City of Kaukauna)
Solid Waste Disposal	Contracted disposal

2.6 Potentially Sensitive Improvements

No improvements of environmental concern were identified at the Property.

POTENTIALLY SENSITIVE IMPROVEMENTS	
Above Ground Storage Tank	None
Clarifier	None
Dry Well	None
Floor Drain	None
Ponds, Pits and Lagoons	None
Septic System	None
Settlement Tank	None
Underground Pipeline	None
Underground Storage Tank	None
Wells	None

2.7 Adjoining Properties

The following activities were observed at adjoining properties.

Direction	Activities	Comments
North	The Fox River	No impact is expected.
South	Bicentennial Court, beyond which are railroad tracks and the City of Kaukauna Municipal Service Department.	No impact is expected.
East	A commercial building occupied by Ghost-Town Fitness Center and a vacant parcel of land owned by Versatile Developments, and intended for future development of the subject property	No impact is expected.
West	Multi-family residences	No impact is expected.

3.0 Client Provided Information

In order to qualify for defenses to CERCLA liability, a defendant must demonstrate the completion of "all appropriate inquiry." As defined by EPA, all appropriate inquiry includes an assessment performed by an environmental professional, in addition to the identification and consideration of certain information not within the scope of a Phase I assessment. The ESA Standard requires the client to provide this information to the environmental professional. When not provided, the missing information must be considered as a possible Data Gap. Information required to be provided by the client includes:

- Research into the existence of environmental cleanup liens and Activity and Use Limitations
- Any specialized knowledge or experience of the "user"
- Commonly known or reasonably ascertainable information about the property
- Relationship of the purchase price to fair market value, and
- The degree of obviousness of the presence or likely presence of contamination.

No related information was provided by the Client. As a lender, the client would not be expected to possess significant information concerning the property. As a result, GRS Group does not view the lack of client-provided information as a significant data gap.

3.1 Owner, Property Manager, and Occupant Information

The following additional information, discussed in relevant sections of the report, was provided by the Property Owner:

- Limited Site Assessment (of Ghost-Town Fitness Center), Terracon, August 10, 2006
- Completed Pre-Survey Questionnaire
- Property Brochure
- A current rent roll

4.0 Records Review

4.1 Regulatory Records

Regulatory records provide an important source of information concerning the current and historical use of hazardous materials at the subject and nearby properties. In order to satisfy ESA Standard requirements for the review of regulatory information, GRS Group obtained aggregated data from a commercial service specializing in the organization and reporting of regulatory information.

Map Findings Summary

Database	Target Property	Search Distance (Miles)	< 1/8	1/8 - 1/4	1/4 - 1/2	1/2 - 1	> 1	Total Plotted

The column for Target Property is blank if no records were found.

4.1.1 Subject Property

No regulatory records for the subject Property were identified during our review. Further, no information was discovered during completion of this Assessment which would lead GRS Group to suspect that records should have been included in the information reviewed. As a result, no additional related Assessment appears warranted.

4.1.2 Off- Site Properties

A release resulting from activities at nearby properties can sometimes impact surrounding properties. Regulatory records concerning nearby properties is reviewed in order to identify a release of hazardous materials which would be expected to impact conditions at the subject Property. The evaluation of nearby properties is a two- fold process, evaluating both identified

releases of hazardous materials, and the potential for such releases to impact the subject Property.

The adjoining property to the east, identified as Ghost-Town Fitness Center, is included on the WI ERP database. The inclusion is due to the site's prior use as a railroad roundhouse. According to a Limited Site Assessment of the site, groundwater was tested in an area that would be considered centrally located on the railyard. The sample collected was found to be below applicable action levels for Volatile Organic Compounds (VOCs), Diesel Range Organics (DRO), and RCRA metals. Based on this information, the Wisconsin Department of Natural Resources (WDNR) closed the WI ERP site on October 9, 2006. Therefore, the historical use of the subject and adjoining property as a railroad yard and roundhouse is considered an on-site and off-site Historical REC (HREC) for which no further actions are required.

Additionally, eighteen (18) LUST sites and six (6) UST sites were identified within the study radii. Seventeen (17) of the identified LUST sites have been closed by the WDNR, indicating that no further actions are required. Therefore, these LUST sites are not considered RECs. The remaining open site, identified as City of Kaukauna Property, is located approximately 0.19 mile to the southeast, and potentially up-gradient of the subject property. This site is also known as the former Gunderson's Cleaners. According to the EDR report, all of the USTs at this have been abandoned in place or removed from the ground. Ongoing remedial activities have been performed at the site since 2002 and currently include groundwater monitoring. Numerous Site Assessment Grants (SAG) have been awarded to cover the costs associated with the remedial activities at this site. Based on the remedial actions taken at this site, and the results of the recent groundwater sampling performed in the immediate vicinity of the subject property, this site is not considered an REC.

Properties of Potential Concern

No properties were identified which are considered likely to result in a release of hazardous materials to the subject Property.

Properties of No Further Concern

No other regulatory listings were identified in completion of our Assessment.

Unmapped Records

Reports of regulatory records for the subject and surrounding Properties are compiled from data files published by public agencies. Data contained in those records is not always adequate to allow available mapping programs to correctly identify the property.

Review of the names and address information for unmapped properties revealed no evidence of records likely to be associated with the subject Property.

4.1.3 Additional Environmental Record Sources

The following additional environmental record sources were reviewed:

Source	Comments
Fire Department	Global contacted the Kaukauna Fire Department for information regarding records of USTs or other potential environmental concerns at the subject property. According to Assistant Chief, Don Grindheim, there are no records of USTs or environmental concerns on file for the subject property.

4.2 Physical Setting

4.2.1 Topography

Topography		
Description	**Findings**	**Source**
Configuration	Relatively flat	Site Observations and topographic map
Elevation	790 feet above mean sea level	Topographic Maps
Surface Water	No water bodies are located on the subject property.	Site Observations and topographic map

4.2.2 Geology

Geology		
Description	**Findings**	**Source**
Formation	Paleozoic Ordovician	P.G. Schruben, R.E. Arndt and W.J. Bawiec, Geology of the Conterminous U.S.
Description	Grays silt loam, consisting of deep and moderately deep, moderately well and well drained soils with moderately coarse textures.	Soil Survey of Outagamie County
Permeability	Moderate	Soil Survey of Outagamie County

4.2.3 Hydrology

Hydrology		
Description	**Findings**	**Source**
Primary Aquifer	Unconsolidated sand and gravel deposits of Quaternary age and consolidated sandstone, limestone, and dolomite of Paleozoic age.	Groundwater Atlas of the United States, reviewed on-line
Estimated first depth to groundwater	Approximately 11-12 feet below ground surface (bgs)	Soil Survey of Outagamie County
Gradient	Toward the west	Inferred from elevation, site observations and proximity to surface water.

4.3 Historical Use

4.3.1 Summary

Immediately prior to the development of the current improvements between 1983 and 1992, the subject property was undeveloped land since the early 1970s. Prior to that date, the subject property was developed with several buildings that were part of a Chicago & Northwestern Railway Shops, according to the review of aerial photographs, Sanborn maps, and historical topographic maps. The railway shops were present since the late 1890s. Specifically, the buildings that comprised the railway shops were a Kimberly-Clark Paper Mill warehouse, a blacksmith shop, and two small outbuildings identified as a warehouse and a supply shed. No direct evidence of a release of hazardous materials was identified.

Activities in the vicinity of the Property have primarily included residential and railyard uses, as well. The adjacent property to the east was developed with the railway roundhouse from the late 1890s through the early 1970s. The adjacent property to the north was part of the

previously mentioned railway shops and was also a paper mill. The railroad tracks have been present on the adjacent property to the south since the late 1880s. As previously discussed, as part of a previous assessment of the adjacent property to the east, groundwater sampling have confirmed that contamination levels are below applicable action levels. The sampling was performed on the adjacent property to the east, in what would be considered a centrally located area of the entire railyard. Therefore, the presence of this former railyard is considered an HREC.

Heating Fuel - Natural gas is the fuel source for the HVAC system at the subject property. There is no evidence that heating oil has ever been used at the Property.

Fill Materials - No evidence of the historical placement of fill materials was identified during our review of historical information. Though the placement of fill materials cannot be ruled out, no significant depressions, pits or other features suggestive of the likely placement of fill were identified in review of historical topographic maps and aerial photos.

Standard Historical Source	Reviewed?	Concerns?	Description of Concerns
Aerial Photographs	Yes	Yes	Former railyard at subject and adjoining properties is considered an HREC, for which no further actions are required.
Fire Insurance Maps	Yes	Yes	Former railyard at subject and adjoining properties is considered an HREC, for which no further actions are required.
Property Tax Files	Yes	No	
Recorded Land Title Records	No		
USGS Topographic Map	Yes	Yes	Former railyard at subject and adjoining properties is considered an HREC, for which no further actions are required.
Local Street Directories	No		
Building Department Records	Yes	No	
Zoning/Land Use Records	Yes	No	
Other Historical Sources	No		
Prior Assessments	Yes	No	Groundwater sampling verified that contamination levels are below applicable action levels.

4.3.2 Aerial Photographs

The following aerial photographs were reviewed:

Source	Year	Scale
EDR	1952	500
EDR	1957	750
EDR	1964	500
EDR	1971	750
EDR	1981	750
EDR	1986	1000
EDR	1992	750
EDR	2005	604

Subject Property

The property was undeveloped between the early 1970s and the construction of the existing structures beginning in 1983. Development of the subject property improvements occurred in phases through 1992, as was evident on the aerial photographs. A railroad yard was present at the subject property between the 1890s and the early 1970s.

Nearby Properties

The general vicinity of the Property included the aforementioned railyard and the associated roundhouse from the 1890s through the early 1970s. Commercial and residential development of the area, began in the early to mid 1970s. As previously discussed, the former railyard and roundhouse are considered HRECs for which no further actions are required. No other improvements or conditions of concern were identified as a result of this review of aerial photographs.

4.3.3 Fire Insurance Maps

Fire insurance maps were reviewed for 1885, 1890, 1894, 1900, 1906, 1913, 1925, 1945, and 1956.

Source	Year
EDR- Sanborn	1885
EDR- Sanborn	1890
EDR- Sanborn	1894
EDR- Sanborn	1900
EDR- Sanborn	1906
EDR- Sanborn	1913
EDR- Sanborn	1925
EDR- Sanborn	1945
EDR- Sanborn	1956

Subject Property - The property is not depicted on the 1885 through 1900 Sanborn Maps. The 1906 through 1956 maps depict the subject property as being developed with several structures identified as the Chicago & Northwestern Railway Shops. These buildings are identified as a Kimberly- Clark Paper Mill warehouse and a blacksmith shop, as well as two smaller outbuildings used as a warehouse and a supply shed.

Nearby Properties - The railroad roundhouse and a building identified as the Combined Locks Paper Company (old telephone book paper warehouse), are evident at properties immediately adjacent to the north and east of the subject Property in the 1884 through the 1956 maps. The adjacent property to the south is shown as railroad tracks on all of the maps reviewed.

4.3.4 Property Tax Files

According to records reviewed at the City of Kaukauna Assessor's website, the subject property consists of three parcels of land which total approximately 2.815 acres. The assessment files did not indicate the age of square footage of the improvements at the subject property. Additionally, no information was found in the assessment files regarding the age of several of the buildings at the subject property.

4.3.5 Recorded Land Title Records

Research and review of recorded land title records was beyond the scope of our assessment.

4.3.6 USGS Topographic Maps

The following topographic maps were reviewed:

Quad	Year	Scale
APPLETON	1955	1:62500
KAUKAUNA	1974	1:24000
KAUKAUNA	1984	1:24000
KAUKAUNA	1992	1:24000

Subject Property

The 1992 map showed the subject property to be in an area where only landmark structures are shown. The subject property was depicted as undeveloped land on the 1974 and 1984 topographic maps. The previously discussed railyard buildings are evident on the 1955 topographic map.

Nearby Properties

Multi-family residential buildings are depicted on the adjacent property to the west on the 1974 and 1984 maps. The previously discussed railyard buildings are evident on the 1955 topographic map. The 1992 map showed the adjoining properties to be in an area where only landmark structures are shown.

4.3.7 Local Street Directories

Based on the historical information obtained from other sources, local street directories were not reviewed as part of this assessment.

4.3.8 Building Department Records

GRS Group contacted the local building department for information regarding any records of file for the subject Property. According to Mr. Dave Raymond, Building Inspector with the Kaukauna Community Development Department, Certificates of Occupancy (COs) were issued for the subject buildings beginning in 1983. Building Department files indicated that the last CO was issued in 2004. Copies of the COs were not available. No records were found that indicated any environmental concerns at the subject property.

4.3.9 Zoning/Land Use Records

Zoning maps reviewed on-line show the Property to be zoned CCD, Commercial Core District. The current use of the property for multi-family residential purposes is consistent with the zoning.

Global contacted the City of Kaukauna Zoning Department for information pertaining to historical zoning of the property. No information was available concerning historical zoning of the Property.

4.3.10 Other Historical Sources

GRS Group researched the Property on-line. No listings of interest were identified.

4.3.11 Prior Assessments

The following prior assessments were provided for our consideration:

- Limited Site Assessment (for Ghost-Town Fitness Center) - Terracon - 2006

Based on the prior use history results of a Transaction Screen, also performed by Terracon and attached to the above referenced report as an appendix, the prior use history of the site as a railyard and roundhouse warranted a subsurface investigation. One soil boring was advanced in an area centrally located on the former railyard. One groundwater sample was collected and analyzed for VOCs, DRO, and RCRA metals. Based on the laboratory results, the levels of all three contaminants were below all applicable action levels.

Terracon concluded "Reported concentrations of VOCs, DRO, and RCRA Metals are generally below applicable standards and do not appear to indicate that a significant historical release occurred on the property. Terracon does not recommend additional assessment. However, as a precautionary measure, due to the detection of DRO in groundwater and also detections of arsenic, lead, and selenium exceeding NR 140 PALs, Terracon recommends the site owner report the detections to the WDNR as required by Section 292.11 of the Wisconsin Statutes, which is also known as the spills law. The statute requires that a person who posses or controls a hazardous substance which is discharged or who causes the discharge of a hazardous substance shall notify the department immediately of any discharge not exempted by law."

4.3.12 Data Failure

No data failure was encountered during the review of historical information. Historical use of the property was researched to 1885, prior to development of the existing structures and before the required cutoff date established by the ESA Standard, 1940. Several periods of more than five years appear among data sources reviewed, however improvements and activities at the property during these periods appears to have been the previously discussed railroad buildings. In accordance with the ESA Standard, such periods are not considered to constitute data failure.

5.0 Site Reconnaissance

No conditions or improvements of environmental concern were observed during our reconnaissance of the property. The site reconnaissance was performed by Andy Bryan on December 7, 2009. We were accompanied by the Key Site Manager, Mr. Tom Vandeyacht, the Property Owner. Weather at that time was clear and provided no obstacle to completion of the reconnaissance.

GRS Group's site reconnaissance of exterior areas included observation of the Property from nearby streets, and along the perimeter of the property and periphery of each building. Open areas of the property were traversed at intervals of approximately 100 feet. Interior observations included all common, maintenance and storage areas and GRS Group's site reconnaissance of exterior areas included observation of the Property from nearby streets, and along the perimeter of the property and periphery of each building. Open areas of the property were traversed at intervals of approximately 100 feet. Interior observations included all common, maintenance and storage areas and units B400-6, B300-6, B400-, B410-1, F400-4, F410-3, and F410-5.

5.1 Common Concerns

No improvements, features or activities were identified which would be expected to indicate the use, storage or disposal of hazardous materials.

Concern	Present?	Comments
Above Ground Storage Tanks	No	
Discharge Features	No	
Equipment Likely to Contain PCBs	No	
Hazardous Material Use	Minor	Building maintenance products, paints, and janitorial products.
Other Suspect Containers	No	
Petroleum Products	No	
Pits, Ponds, and Lagoons	No	
Processes of Concern	No	
Solid Waste Dumping/Landfills	No	
Stained Soil/Stressed Vegetation	No	
Staining/Corrosion	No	
Stockpiled Soils	No	
Subsidence	No	
Surface Repairs (e.g. UST removal)	No	
Underground Storage Tanks	No	
Wells	No	

No concerns were identified that are expected to impact the subject property.

5.2 Additional Concerns

No additional concerns were identified.

5.3 Adjoining Properties

The following activities and improvements were observed at adjoining properties.

North - The Fox River.

South - Railroad tracks and Bicentennial Court, beyond which are City of Kaukauna Municipal Service buildings..

East - The Ghost-Town Fitness Center.

West - Multi-family residences.

No activities or improvements were observed which would be expected to have resulted in impact to environmental conditions at the subject Property.

6.0 Interviews

Interviews were conducted with the following persons and/or agencies:

Position	Name	Company	Title	Contact Information	Interview Date
Current Owner	Mr. Tom Vandeyacht (also Key Site Manager)	Versatile Developments Company, LLC	Owner.Managing Member	920-213-7145	December 7, 2009
Local Government Official	Mr. Dave Raymond	City of Kaukauna Community Development Department	Building Inspector	920-766-6325	December 9, 2009

Key Site Manager

Mr. Tom Vandeyacht, the Property Owner, is also the Key Site Manager for the subject property. He has owned the Property since the early 1990s and stated that he was not aware of any environmental concerns at the site. Mr. Vandeyacht provided Global with a previous environmental report for the site, as well as a completed Pre-Survey Questionnaire, a current rent roll, and a property brochure. Copies of the reports that were provided for review have been discussed above.

Current Occupants

Interview of current occupants is not required for residential properties. Since GRS Group found no areas in which such interviews would be expected to provide meaningful information, interviews were not conducted with current and past occupants.

Local Government Officials

Building Department - GRS Group interviewed Mr. Dave Raymond, Building Inspector with the Kaukauna Community Development Department. According to Mr. Raymond, COs were issued for the subject buildings beginning in 1983. Copies of the COs were not available. No records were found that indicated any environmental concerns at the subject property.

7.0 Additional Services

Additional services were provided as follows:

Asbestos Containing Building Materials

During completion of the site reconnaissance, GRS Group looked for building materials commonly believed to contain asbestos. Where appropriate, samples of suspect ACM were collected and submitted for laboratory analysis by polarized light microscopy. This assessment provides a screening for the presence of asbestos containing materials to assist in understanding of business risks associated with the property, but is not intended and may not be used for the satisfaction of regulatory requirements and is not a suitable replacement for pre-demolition or other more in-depth studies.

Asbestos-containing building materials may be present at the Property. Asbestos has historically been present in a wide variety of building materials, though the use of asbestos containing materials has significantly decreased since 1981. The Property was constructed after the use of most friable ACMs had been discontinued. During completion of our site reconnaissance, GRS Group identified materials which may contain asbestos, including vinyl floor tile, drywall, joint compound, exterior shingles, as well as roofing felt and coatings. These materials were not sampled since they were found to be in good condition at the time of our Assessment. No friable or damaged suspect ACM was observed at the Property.

All suspect materials should be handled with due caution and in accordance with applicable regulations.

Lead-Based Paint

No suspect lead-based paint was identified at the Property. The use of lead-based was banned in 1978, prior to construction of improvements at the Property.

Drinking Water

Drinking water is supplied by the City of Kaukauna and is reported to be in compliance with applicable regulations.

Radon

The USEPA has prepared a map to assist National, State, and local organizations to target their resources and to implement radon-resistant building codes. The map divides the country into three Radon Zones, Zone 1 being those areas with the average predicted indoor radon concentration in residential dwellings exceeding the EPA Action limit of 4.0 picoCuries per Liter (pCi/L). It is important to note that the EPA has found homes with elevated levels of radon in all three zones, and the EPA recommends site specific testing in order to determine radon levels at a specific location. However, the map does give a valuable indication of the propensity of radon gas accumulation in structures. Review of the EPA Map of Radon Zones places the Property in Zone 2, where average predicted radon levels are between 2.0 and 4.0 pCi/L.

At the time of site reconnaissance, five radon canisters were placed in residential units located on the ground floor of the building. The canisters were retrieved by the property contact and forwarded for analysis. The results of the analyses are provided below:

Location	Sample #	Results	Comments
F400-4, Kitchen	2106841	1.3	Below the EPA Action Level of 4.0 Pcl/L
F410-5, Kitchen	2106841	1.0	Below the EPA Action Level of 4.0 Pcl/L
B410-1, Kitchen	2106840	1.7	Below the EPA Action Level of 4.0 Pcl/L

Based on the laboratory results and radon zone, radon is not considered a concern at the subject property.

Mold

Mr. Vandeyacht was interviewed during our assessment, and had no knowledge of past or present areas of mold growth or moisture intrusion at the Property or of related tenant complaints. During our site reconnaissance, no significant evidence was identified to indicate current or past mold growth or moisture intrusion likely to result in mold growth. Minor mold growth, due to humidity, was observed in a utility room housing the water softening equipment. The mold can cleaned with bleach as part of routine maintenance.

Wetlands

No wetlands were identified at the subject property.

Indoor Air Quality

In accordance with Tier I vapor intrusion evaluation criteria, the evaluation of potential vapor intrusion into buildings is appropriate when soil or groundwater impacted by volatile organic hydrocarbons is located within 90 feet of a structure, or hydrocarbon impacts to soil or groundwater are identified within 30 feet of a structure. Global has conducted a Tier I evaluation of vapor intrusion consisting of interview of the key site manager and consideration of other results of this Assessment.

No suspected release of hazardous materials to soil or ground water has been identified within critical distances established by Tier I ASTM criteria. As a result, no additional assessment of potential indoor air quality impacts is indicated by Tier I ASTM criteria.

Compliance

No activities or conditions requiring compliance with environmental regulation were identified.

8.0 Certification

We declare that, to the best of our professional knowledge and belief, we meet the definition of Environmental Professional as defined in section 312.10 of 40 CFR 312, and we have the specific qualifications based on education, training, and experience to assess a property of the nature, history, and setting of the subject Property. We have developed and performed the all appropriate inquiries in conformance with the standards and practices set forth in 40 CFR Part 312 except as follows:

- The results of additional inquiries required under section 312.22 of 40 CFR 312 were not provided to the environmental professional. All appropriate inquiry does not require submission of this information to the environmental professional, but without this information we are unable to make a declaration regarding related conformance with the requirements of 40 CFR 312.

In order to qualify for innocent landowner, contiguous property owner, or bona fide prospective purchaser protections under CERCLA, any user of this assessment should assure conformance with these requirements.

Andy Bryan
Field Professional

Limitations of ESA Standard

Exclusions from and Limitations of the ESA Standard

General

The following information concerning exclusions from the ESA standard is provided for clarification and is not intended to reduce or limit similar clarifications contained within the ESA Standard. Certain inherent limitations in the ESA Standard are discussed here; however the reader should review the full standard in order to assure an appropriate understanding of work.

Principles of the ESA Standard

Considerations Beyond Scope—The use of this practice is strictly limited to the scope set forth in this section. Section 13 of this practice identifies, for informational purposes, certain environmental conditions (not an all-inclusive list) that may exist on a property that are beyond the scope of this practice but may warrant consideration by parties to a commercial real estate transaction. The need to include an investigation of any such conditions in the environmental professional's scope of services should be evaluated based upon, among other factors, the nature of the property and the reasons for performing the assessment (for example, a more comprehensive evaluation of business environmental risk) and should be agreed upon between the user and environmental professional as additional services beyond the scope of this practice prior to initiation of the environmental site assessment process

CERCLA Requirements Other Than Appropriate Inquiry—This practice does not address whether requirements in addition to all appropriate inquiry have been met in order to qualify for the LLPs (for example, the duties specified in 42 U.S.C. §9607(b)(3)(a) and (b) and cited in Appendix X1, including the continuing obligation not to impede the integrity and effectiveness of activity and use limitations (AULs), or the duty to take reasonable steps to prevent releases, or the duty to comply with legally required release reporting obligations).

Other Federal, State, and Local Environmental Laws—This practice does not address requirements of any state or local laws or of any federal laws other than the all appropriate inquiry provisions of the LLPs. Users are cautioned that federal, state, and local laws may impose environmental assessment obligations that are beyond the scope of this practice. Users should also be aware that there are likely to be other legal obligations with regard to hazardous substances or petroleum products discovered on the property that are not addressed in this practice and that may pose risks of civil and/or criminal sanctions for non-compliance.

Practically Reviewable—information that is practically reviewable means that the information is provided by the source in a manner and in a form that, upon examination, yields information relevant to the property without the need for extraordinary analysis of irrelevant data. The form of the information shall be such that the user can review the records for a limited geographic area. Records that cannot be feasibly retrieved by reference to the location of the property or a geographic area in which the property is located are not generally practically reviewable. Most databases of public records are practically reviewable if they can be obtained from the source agency by the county, city, zip code, or other geographic area of the facilities listed in the record system. Records that are sorted, filed, organized, or maintained by the source agency only chronologically are not generally practically reviewable. Listings in publicly available records which do not have adequate address information to be located geographically are not generally considered practically reviewable. For large databases with numerous records (such as RCRA hazardous waste generators and registered underground storage tanks), the records are not practically reviewable unless they can be obtained from the source agency in the smaller geographic area of zip codes. Even when information is provided by zip code for some large

databases, it is common for an unmanageable number of sites to be identified within a given zip code. In these cases, it is not necessary to review the impact of all of the sites that are likely to be listed in any given zip code because that information would not be practically reviewable. In other words, when so much data is generated that it cannot be feasibly reviewed for its impact on the property, it is not practically reviewable.

Reasonably Ascertainable—information that is (1) publicly available, (2) obtainable from its source within reasonable time and cost constraints, and (3) practically reviewable.

Non-Scope Considerations

(Excerpted from the ESA Standard)

The following are identified as "Non-Scope Considerations under the ESA Standard. Unless the expressly identified in the agreed proposal for services, all tasks identified below are excluded from this Assessment.

13.1 General:

13.1.1 Additional Issues—There may be environmental issues or conditions at a property that parties may wish to assess in connection with commercial real estate that are outside the scope of this practice (the non-scope considerations). As noted by the legal analysis in Appendix X1 of this practice, some substances may be present on a property in quantities and under conditions that may lead to contamination of the property or of nearby properties but are not included in CERCLA's definition of hazardous substances (42 U.S.C. §9601(14)) or do not otherwise present potential CERCLA liability. In any case, they are beyond the scope of this practice.

13.1.2 Outside Standard Practices—Whether or not a user elects to inquire into non-scope considerations in connection with this practice or any other environmental site assessment, no assessment of such non-scope considerations is required for appropriate inquiry as defined by this practice.

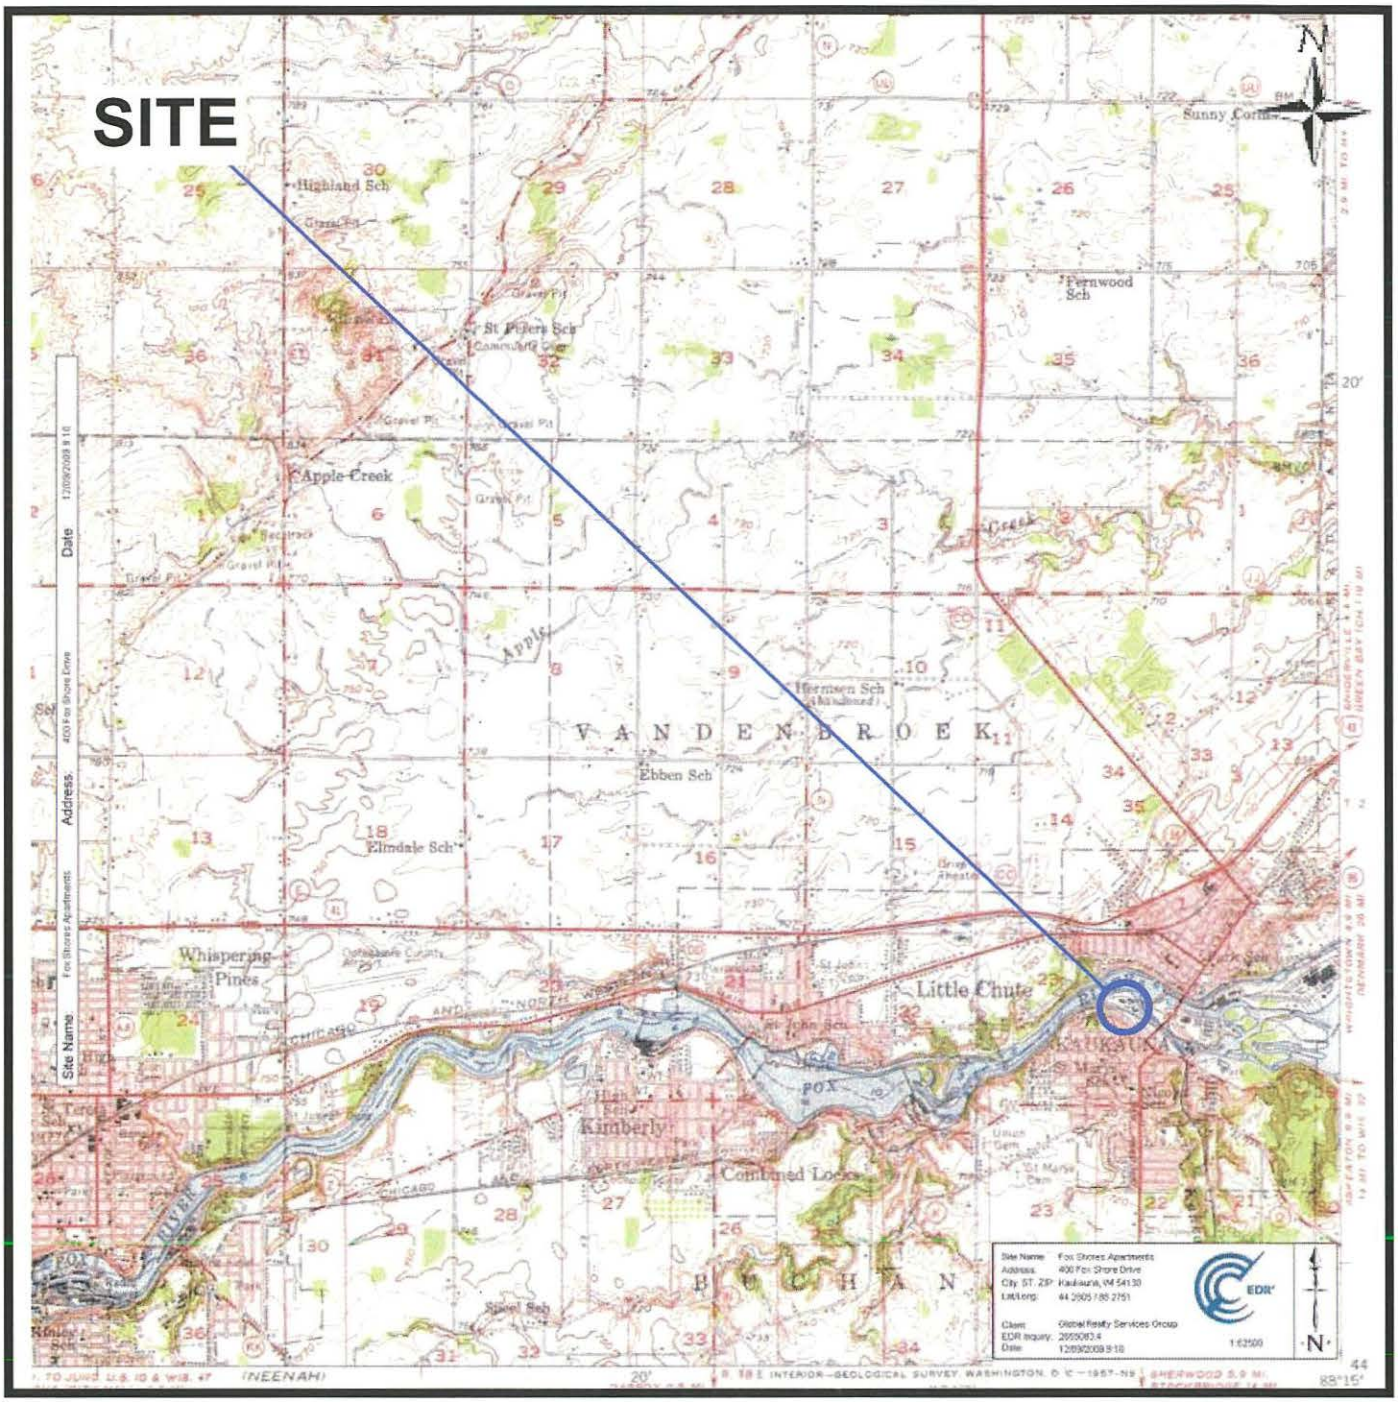
13.1.3 Other Standards—There may be standards or protocols for assessment of potential hazards and conditions associated with non-scope conditions developed by governmental entities, professional organizations, or other private entities.

13.1.4 Compliance With AULs—Parties who wish to qualify for one of the LLPs will need to know whether they are in compliance with AULs, including land use restrictions that were relied upon in connection with a response action. A determination of compliance with AULs is beyond the scope of this practice.

13.1.5 List of Additional Issues—Following are several non-scope considerations that persons may want to assess in connection with commercial real estate. No implication is intended as to the relative importance of inquiry into such non-scope considerations, and this list of non-scope considerations is not intended to be all-inclusive:

13.1.5.1 Asbestos-Containing Building Materials,

13.1.5.8 Industrial hygiene,



13.1.5.2 Radon,
13.1.5.3 Lead-Based Paint,
13.1.5.4 Lead in Drinking Water,
13.1.5.5 Wetlands,
13.1.5.6 Regulatory compliance,
13.1.5.7 Cultural and historic resources,
13.1.5.9 Health and safety,
13.1.5.10 Ecological resources,
13.1.5.11 Endangered species,
13.1.5.12 Indoor air quality,
13.1.5.13 Biological agents, and
13.1.5.14 Mold.

Activity Exclusions

- Accessing manholes or utility pit
- Entering of plenum, crawl, or confined space areas (however, the field observer should observe conditions to the extent easily visible from the point of access to the crawl or confined space areas, provided such points of access are readily accessible), determination of previous substructure flooding or water penetration unless easily visible or if such information is provided
- Walking on pitched roofs, or any roof areas that appear to be unsafe, or roofs with no built-in access, or determining any roofing design criteria
- Testing and design of equipment
- Collection of samples except as identified in the agreement under which the work is performed.
- Removing, relocating, or repositioning of materials, ceiling, wall, or equipment panels, furniture, storage containers, personal effects, debris material or finishes; conducting exploratory probing or testing; dismantling or operating of equipment; or disturbing personal items or property, that obstructs access or visibility,
- Preparing engineering calculations to determine any the adequacy or compliance of systems and components,
- Reporting on subterranean conditions
- Entering or accessing any area of the premises deemed to potentially pose a threat of dangerous or adverse conditions with respect to the field observer's health or safety, or to perform any procedure, that may damage or impair the physical integrity of the property, any system, or component.
- Compliance with any federal, state, or local statute, ordinance, rule or regulation including, but not limited to, fire and building codes, life safety codes, environmental regulations, health codes, zoning ordinances, compliance with trade design standards, or standards developed by the insurance industry.
- Compliance of any material, equipment, or system with any certification or actuation rate program, vendor's or manufacturer's warranty provisions, or provisions established by any standards that are related to insurance industry acceptance/approval, such as FM, State Board of Fire Under- writers, etc.

EXECUTIVE SUMMARY

A search of available environmental records was conducted by Environmental Data Resources, Inc (EDR). The report was designed to assist parties seeking to meet the search requirements of EPA's Standards and Practices for All Appropriate Inquiries (40 CFR Part 312), the ASTM Standard Practice for Environmental Site Assessments (E 1527-05) or custom requirements developed for the evaluation of environmental risk associated with a parcel of real estate.

TARGET PROPERTY SEARCH RESULTS

The target property was not listed in any of the databases searched by EDR.

DATABASES WITH NO MAPPED SITES

No mapped sites were found in EDR's search of available ("reasonably ascertainable ") government records either on the target property or within the search radius around the target property for the following databases:

SURROUNDING SITES: SEARCH RESULTS

Surrounding sites were identified in the following databases.

Elevations have been determined from the USGS Digital Elevation Model and should be evaluated on a relative (not an absolute) basis. Relative elevation information between sites of close proximity should be field verified. Sites with an elevation equal to or higher than the target property have been differentiated below from sites with an elevation lower than the target property.
Page numbers and map identification numbers refer to the EDR Radius Map report where detailed data on individual sites can be reviewed.

Sites listed in ***bold italics*** are in multiple databases.

Unmappable (orphan) sites are not considered in the foregoing analysis.

STANDARD ENVIRONMENTAL RECORDS

Federal RCRA CORRACTS facilities list

CORRACTS: CORRACTS is a list of handlers with RCRA Corrective Action Activity. This report shows which nationally-defined corrective action core events have occurred for every handler that has had corrective action activity.

A review of the CORRACTS list, as provided by EDR, and dated 09/15/2009 has revealed that there is 1 CORRACTS site within approximately 1 mile of the target property.

EXECUTIVE SUMMARY

Federal RCRA generators list

RCRA-CESQG: RCRAInfo is EPA's comprehensive information system, providing access to data supporting the Resource Conservation and Recovery Act (RCRA) of 1976 and the Hazardous and Solid Waste Amendments (HSWA) of 1984. The database includes selective information on sites which generate, transport, store, treat and/or dispose of hazardous waste as defined by the Resource Conservation and Recovery Act (RCRA). Conditionally exempt small quantity generators (CESQGs) generate less than 100 kg of hazardous waste, or less than 1 kg of acutely hazardous waste per month.

A review of the RCRA-CESQG list, as provided by EDR, and dated 11/12/2008 has revealed that there are 3 RCRA-CESQG sites within approximately 0.25 miles of the target property.

State and tribal institutional control / engineering control registries

AUL: Date a deed restriction is recorded at the Register of Deeds office for a property. Extent of soil contamination is known but impracticable to remove now or an engineering control is required to be maintained or NR720 industrial stds are applied. Restricts property use or requires future actions.

A review of the AUL list, as provided by EDR, and dated 10/22/2009 has revealed that there are 11 AUL sites within approximately 0.5 miles of the target property.

EXECUTIVE SUMMARY

State and tribal Brownfields sites

BROWNFIELDS: A listing of brownfields sites included in the BRRTS database. Brownfields are abandoned, idle or underused commercial or industrial properties, where the expansion or redevelopment is hindered by real or perceived contamination. Brownfields vary in size, location, age, and past use -- they can be anything from a five-hundred acre automobile assembly plant to a small, abandoned corner gas station.

A review of the BROWNFIELDS list, as provided by EDR, and dated 10/22/2009 has revealed that there are 2 BROWNFIELDS sites within approximately 0.5 miles of the target property.

ADDITIONAL ENVIRONMENTAL RECORDS

Local Lists of Hazardous waste / Contaminated Sites

WI ERP: Emergency Repair Program Database. Non - LUST Sites with Contaminated Soil and/or GW. Often these are historic releases to the environment.

A review of the WI ERP list, as provided by EDR, and dated 10/22/2009 has revealed that there are 5 WI ERP sites within approximately 0.5 miles of the target property.

Other Ascertainable Records

RCRA-NonGen: RCRAInfo is EPA's comprehensive information system, providing access to data supporting the Resource Conservation and Recovery Act (RCRA) of 1976 and the Hazardous and Solid Waste Amendments (HSWA) of 1984. The database includes selective information on sites which generate, transport, store, treat and/or dispose of hazardous waste as defined by the Resource Conservation and Recovery Act (RCRA). Non-Generators do not presently generate hazardous waste.

A review of the RCRA-NonGen list, as provided by EDR, and dated 11/12/2008 has revealed that there are 2 RCRA-NonGen sites within approximately 0.25 miles of the target property.

Off-site waste receiver: Commercial status unknown

Hazardous Waste Summary:
Waste code: D001
Waste name: IGNITABLE HAZARDOUS WASTES ARE THOSE WASTES WHICH HAVE A FLASHPOINT OF LESS THAN 140 DEGREES FAHRENHEIT AS DETERMINED BY A PENSKY-MARTENS CLOSED CUP FLASH POINT TESTER. ANOTHER METHOD OF DETERMINING THE FLASH POINT OF A WASTE IS TO REVIEW THE MATERIAL SAFETY DATA SHEET, WHICH CAN BE OBTAINED FROM THE MANUFACTURER OR DISTRIBUTOR OF THE MATERIAL. LACQUER THINNER IS AN EXAMPLE OF A COMMONLY USED SOLVENT WHICH WOULD BE CONSIDERED AS IGNITABLE HAZARDOUS WASTE.

Waste code: D018
Waste name: BENZENE

Classification: Not a generator, verified

Hazardous Waste Summary:
Waste code: D001
Waste name: IGNITABLE HAZARDOUS WASTES ARE THOSE WASTES WHICH HAVE A FLASHPOINT OF LESS THAN 140 DEGREES FAHRENHEIT AS DETERMINED BY A PENSKY-MARTENS CLOSED CUP FLASH POINT TESTER. ANOTHER METHOD OF DETERMINING THE FLASH POINT OF A WASTE IS TO REVIEW THE MATERIAL SAFETY DATA SHEET, WHICH CAN BE OBTAINED FROM THE MANUFACTURER OR DISTRIBUTOR OF THE MATERIAL. LACQUER THINNER IS AN EXAMPLE OF A COMMONLY USED SOLVENT WHICH WOULD BE CONSIDERED AS IGNITABLE HAZARDOUS WASTE.

Waste code: D005
Waste name: BARIUM

Waste code: K086
Waste name: SOLVENT WASHES AND SLUDGES, CAUSTIC WASHES AND SLUDGES, OR WATER WASHES AND SLUDGES FROM CLEANING TUBS AND EQUIPMENT USED IN THE FORMULATION OF INK FROM PIGMENTS, DRIERS, SOAPS, AND STABILIZERS CONTAINING CHROMIUM AND LEAD.

Waste code: D000

K R WEST COMPANY INCORPORATED (Continued) **1000106723**

Waste name: Not Defined

Waste code: D001
Waste name: IGNITABLE HAZARDOUS WASTES ARE THOSE WASTES WHICH HAVE A FLASHPOINT OF LESS THAN 140 DEGREES FAHRENHEIT AS DETERMINED BY A PENSKY-MARTENS CLOSED CUP FLASH POINT TESTER. ANOTHER METHOD OF DETERMINING THE FLASH POINT OF A WASTE IS TO REVIEW THE MATERIAL SAFETY DATA SHEET, WHICH CAN BE OBTAINED FROM THE MANUFACTURER OR DISTRIBUTOR OF THE MATERIAL. LACQUER THINNER IS AN EXAMPLE OF A COMMONLY USED SOLVENT WHICH WOULD BE CONSIDERED AS IGNITABLE HAZARDOUS WASTE.

Waste code: D002
Waste name: A WASTE WHICH HAS A PH OF LESS THAN 2 OR GREATER THAN 12.5 IS CONSIDERED TO BE A CORROSIVE HAZARDOUS WASTE. SODIUM HYDROXIDE, A CAUSTIC SOLUTION WITH A HIGH PH, IS OFTEN USED BY INDUSTRIES TO CLEAN OR DEGREASE PARTS. HYDROCHLORIC ACID, A SOLUTION WITH A LOW PH, IS USED BY MANY INDUSTRIES TO CLEAN METAL PARTS PRIOR TO PAINTING. WHEN THESE CAUSTIC OR ACID SOLUTIONS BECOME CONTAMINATED AND MUST BE DISPOSED, THE WASTE WOULD BE A CORROSIVE HAZARDOUS WASTE.

Waste code: D005
Waste name: BARIUM

Waste code: F002
Waste name: THE FOLLOWING SPENT HALOGENATED SOLVENTS: TETRACHLOROETHYLENE, METHYLENE CHLORIDE, TRICHLOROETHYLENE, 1,1,1-TRICHLOROETHANE, CHLOROBENZENE, 1,1,2-TRICHLORO-1,2,2-TRIFLUOROETHANE, ORTHO-DICHLOROBENZENE, TRICHLOROFLUOROMETHANE, AND 1,1,2-TRICHLOROETHANE; ALL SPENT SOLVENT MIXTURES/BLENDS CONTAINING, BEFORE USE, A TOTAL OF TEN PERCENT OR MORE (BY VOLUME) OF ONE OR MORE OF THE ABOVE HALOGENATED SOLVENTS OR THOSE LISTED IN F001, F004, OR F005, AND STILL BOTTOMS FROM THE RECOVERY OF THESE SPENT SOLVENTS AND SPENT SOLVENT MIXTURES.

Waste code: F003
Waste name: THE FOLLOWING SPENT NON-HALOGENATED SOLVENTS: XYLENE, ACETONE, ETHYL ACETATE, ETHYL BENZENE, ETHYL ETHER, METHYL ISOBUTYL KETONE, N-BUTYL ALCOHOL, CYCLOHEXANONE, AND METHANOL; ALL SPENT SOLVENT MIXTURES/BLENDS CONTAINING, BEFORE USE, ONLY THE ABOVE SPENT NON-HALOGENATED SOLVENTS; AND ALL SPENT SOLVENT MIXTURES/BLENDS CONTAINING, BEFORE USE, ONE OR MORE OF THE ABOVE NON-HALOGENATED SOLVENTS, AND, A TOTAL OF TEN PERCENT OR MORE (BY VOLUME) OF ONE OR MORE OF THOSE SOLVENTS LISTED IN F001, F002, F004, AND F005, AND STILL BOTTOMS FROM THE RECOVERY OF THESE SPENT SOLVENTS AND SPENT SOLVENT MIXTURES.

Waste code: F005
Waste name: THE FOLLOWING SPENT NON-HALOGENATED SOLVENTS: TOLUENE, METHYL ETHYL KETONE, CARBON DISULFIDE, ISOBUTANOL, PYRIDINE, BENZENE, 2-ETHOXYETHANOL, AND 2-NITROPROPANE; ALL SPENT SOLVENT MIXTURES/BLENDS CONTAINING, BEFORE USE, A TOTAL OF TEN PERCENT OR MORE (BY VOLUME) OF ONE OR MORE OF THE ABOVE NON-HALOGENATED SOLVENTS OR THOSE SOLVENTS LISTED IN F001, F002, OR F004; AND STILL BOTTOMS FROM THE RECOVERY OF THESE SPENT SOLVENTS AND SPENT SOLVENT MIXTURES.

Waste code: K086
Waste name: SOLVENT WASHES AND SLUDGES, CAUSTIC WASHES AND SLUDGES, OR WATER

K R WEST COMPANY INCORPORATED (Continued) **1000106723**

WASHES AND SLUDGES FROM CLEANING TUBS AND EQUIPMENT USED IN THE FORMULATION OF INK FROM PIGMENTS, DRIERS, SOAPS, AND STABILIZERS CONTAINING CHROMIUM AND LEAD.

Environmental Interest/Information System

RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

GOVERNMENT RECORDS SEARCHED / DATA CURRENCY TRACKING

To maintain currency of the following federal and state databases, EDR contacts the appropriate governmental agency on a monthly or quarterly basis, as required.

Number of Days to Update: Provides confirmation that EDR is reporting records that have been updated within 90 days from the date the government agency made the information available to the public.

STANDARD ENVIRONMENTAL RECORDS

Federal NPL site list

NPL: National Priority List

National Priorities List (Superfund). The NPL is a subset of CERCLIS and identifies over 1,200 sites for priority cleanup under the Superfund Program. NPL sites may encompass relatively large areas. As such, EDR provides polygon coverage for over 1,000 NPL site boundaries produced by EPA's Environmental Photographic Interpretation Center (EPIC) and regional EPA offices.

Proposed NPL: Proposed National Priority List Sites

A site that has been proposed for listing on the National Priorities List through the issuance of a proposed rule in the Federal Register. EPA then accepts public comments on the site, responds to the comments, and places on the NPL those sites that continue to meet the requirements for listing.

NPL LIENS: Federal Superfund Liens

Federal Superfund Liens. Under the authority granted the USEPA by CERCLA of 1980, the USEPA has the authority to file liens against real property in order to recover remedial action expenditures or when the property owner received notification of potential liability. USEPA compiles a listing of filed notices of Superfund Liens.

Federal RCRA generators list

RCRA-LQG: RCRA - Large Quantity Generators

RCRAInfo is EPA's comprehensive information system, providing access to data supporting the Resource Conservation and Recovery Act (RCRA) of 1976 and the Hazardous and Solid Waste Amendments (HSWA) of 1984. The database includes selective information on sites which generate, transport, store, treat and/or dispose of hazardous waste as defined by the Resource Conservation and Recovery Act (RCRA). Large quantity generators (LQGs) generate over 1,000 kilograms (kg) of hazardous waste, or over 1 kg of acutely hazardous waste per month.

Data Release Frequency: Quarterly

RCRA-SQG: RCRA - Small Quantity Generators

RCRAInfo is EPA's comprehensive information system, providing access to data supporting the Resource Conservation and Recovery Act (RCRA) of 1976 and the Hazardous and Solid Waste Amendments (HSWA) of 1984. The database includes selective information on sites which generate, transport, store, treat and/or dispose of hazardous waste as defined by the Resource Conservation and Recovery Act (RCRA). Small quantity generators (SQGs) generate between 100 kg and 1,000 kg of hazardous waste per month.

RCRA-CESQG: RCRA - Conditionally Exempt Small Quantity Generators

RCRAInfo is EPA's comprehensive information system, providing access to data supporting the Resource Conservation and Recovery Act (RCRA) of 1976 and the Hazardous and Solid Waste Amendments (HSWA) of 1984. The database includes selective information on sites which generate, transport, store, treat and/or dispose of hazardous waste as defined by the Resource Conservation and Recovery Act (RCRA). Conditionally exempt small quantity generators (CESQGs) generate less than 100 kg of hazardous waste, or less than 1 kg of acutely hazardous waste per month.

State- and tribal - equivalent CERCLIS

SHWS: Hazard Ranking List

State Hazardous Waste Sites. State hazardous waste site records are the states' equivalent to CERCLIS. These sites may or may not already be listed on the federal CERCLIS list. Priority sites planned for cleanup using state funds (state equivalent of Superfund) are identified along with sites where cleanup will be paid for by potentially responsible parties. Available information varies by state.

Date of Government Version: 11/30/1994

State and tribal landfill and/or solid waste disposal site lists

SWF/LF: List of Licensed Landfills

Solid Waste Facilities/Landfill Sites. SWF/LF type records typically contain an inventory of solid waste disposal facilities or landfills in a particular state. Depending on the state, these may be active or inactive facilities or open dumps that failed to meet RCRA Subtitle D Section 4004 criteria for solid waste landfills or disposal sites.

Date of Government Version: 10/07/2009

State and tribal institutional control / engineering control registries

CRS: Closed Remediation Sites

A Closed Remediation Site is parcel of land at which the groundwater has become contaminated and which is affected by a particular type of legal restriction. Specifically, certain steps have been taken to stabilize/remediate the contamination, and the state is satisfied that no further efforts are necessary provided that the property is not used for certain purposes.

Date of Government Version: 11/23/2009
Date Data Arrived at EDR: 11/23/2009

State and tribal Brownfields sites

BEAP: Brownfields Environmental Assessment Program
The Brownfields Environmental Assessment Program (BEAP) was a federal program that assisted municipalities with Environmental Site Assessments (ESA's) for tax delinquent or bankrupt properties, or properties a local government acquired for redevelopment. Using federal dollars, site assessments were conducted by Department of Natural Resources (DNR) staff to determine if the properties were contaminated.

Date of Government Version: 12/31/2000
Date Data Arrived at EDR: 05/29/2001
Date Made Active in Reports: 06/29/2001
Number of Days to Update: 31

Source: Department of Natural Resources

ADDITIONAL ENVIRONMENTAL RECORDS

Local Brownfield lists

US BROWNFIELDS: A Listing of Brownfields Sites
Included in the listing are brownfields properties addresses by Cooperative Agreement Recipients and brownfields properties addressed by Targeted Brownfields Assessments. Targeted Brownfields Assessments-EPA's Targeted Brownfields Assessments (TBA) program is designed to help states, tribes, and municipalities--especially those without EPA Brownfields Assessment Demonstration Pilots--minimize the uncertainties of contamination often associated with brownfields. Under the TBA program, EPA provides funding and/or technical assistance for environmental assessments at brownfields sites throughout the country. Targeted Brownfields Assessments supplement and work with other efforts under EPA's Brownfields Initiative to promote cleanup and redevelopment of brownfields. Cooperative Agreement Recipients-States, political subdivisions, territories, and Indian tribes become Brownfields Cleanup Revolving Loan Fund (BCRLF) cooperative agreement recipients when they enter into BCRLF cooperative agreements with the U.S. EPA. EPA selects BCRLF cooperative agreement recipients based on a proposal and application process. BCRLF cooperative agreement recipients must use EPA funds provided through BCRLF cooperative agreement for specified brownfields-related cleanup activities.

AG SPILLS: Agricultural Spill Cases

Spills reported to the Department of Agriculture, Trade & Consumer Protection. There are two types of spills. Long-term: These are mainly pesticide and fertilizer cases. Some might include other contaminants at the same site. Some might involve wood-treaters - which use pesticides. All of them involve spills of products, but these spills generally result from day to day use (chronic spills) rather than accidental spills (acute). Accidental: These are the acute spills of pesticides and fertilizers and only involve pesticides and fertilizers. Most of these are cleaned up and closed within 3 to 6 months.

UMTRA: Uranium Mill Tailings Sites
Uranium ore was mined by private companies for federal government use in national defense programs. When the mills shut down, large piles of the sand-like material (mill tailings) remain after uranium has been extracted from the ore. Levels of human exposure to radioactive materials from the piles are low; however, in some cases tailings were used as construction materials before the potential health hazards of the tailings were recognized.

HIST FTTS: FIFRA/TSCA Tracking System Administrative Case Listing
A complete administrative case listing from the FIFRA/TSCA Tracking System (FTTS) for all ten EPA regions. The information was obtained from the National Compliance Database (NCDB). NCDB supports the implementation of FIFRA (Federal Insecticide, Fungicide, and Rodenticide Act) and TSCA (Toxic Substances Control Act). Some EPA regions are now closing out records. Because of that, and the fact that some EPA regions are not providing EPA Headquarters with updated records, it was decided to create a HIST FTTS database. It included records that may not be included in the newer FTTS database updates. This database is no longer updated.

RAATS: RCRA Administrative Action Tracking System

RCRA Administration Action Tracking System. RAATS contains records based on enforcement actions issued under RCRA pertaining to major violators and includes administrative and civil actions brought by the EPA. For administration actions after September 30, 1995, data entry in the RAATS database was discontinued. EPA will retain a copy of the database for historical records. It was necessary to terminate RAATS because a decrease in agency resources made it impossible to continue to update the information contained in the database.

BRRTS: Bureau of Remediation & Redevelopment Tracking System

BRRTS is a tracking system of contaminated sites. It holds key information for finding out more about a site or an activity. Activity types included are: Abandoned Container - An abandoned container with potentially hazardous contents recovered from a site. No discharge to the environment occurs. If the container did release a hazardous substance, a spill would be associated with the site. Superfund - is a federal program created by Congress in 1980 to finance cleanup of the nation's worst hazardous waste sites. VPLE - Voluntary Property Liability Exemptions apply to sites in which a property owner conducts an environmental investigation and cleanup of an entire property and then receives limits on their future liability. General Property - Environmental actions which apply to the property as a whole, rather than a specific source of contamination, such as the LUST or environmental repair site. Examples would be off-site letters, municipal liability clarification letters, lease letters, voluntary party liability exemption actions, and general liability clarification letters.

GOVERNMENT RECORDS SEARCHED / DATA CURRENCY TRACKING

EDR PROPRIETARY RECORDS

EDR Proprietary Records

Manufactured Gas Plants: EDR Proprietary Manufactured Gas Plants

The EDR Proprietary Manufactured Gas Plant Database includes records of coal gas plants (manufactured gas plants) compiled by EDR's researchers. Manufactured gas sites were used in the United States from the 1800's to 1950's to produce a gas that could be distributed and used as fuel. These plants used whale oil, rosin, coal, or a mixture of coal, oil, and water that also produced a significant amount of waste. Many of the byproducts of the gas production, such as coal tar (oily waste containing volatile and non-volatile chemicals), sludges, oils and other compounds are potentially hazardous to human health and the environment. The byproduct from this process was frequently disposed of directly at the plant site and can remain or spread slowly, serving as a continuous source of soil and groundwater contamination.

OTHER DATABASE(S)

Depending on the geographic area covered by this report, the data provided in these specialty databases may or may not be complete. For example, the existence of wetlands information data in a specific report does not mean that all wetlands in the area covered by the report are included. Moreover, the absence of any reported wetlands information does not necessarily mean that wetlands do not exist in the area covered by the report.

CT MANIFEST: Hazardous Waste Manifest Data

Facility and manifest data. Manifest is a document that lists and tracks hazardous waste from the generator through transporters to a tsd facility.

USGS TOPOGRAPHIC MAP

Target Property Map:	44088-C3 KAUKAUNA, WI
Most Recent Revision:	1995

EDR's GeoCheck Physical Setting Source Addendum is provided to assist the environmental professional in forming an opinion about the impact of potential contaminant migration.

Assessment of the impact of contaminant migration generally has two principle investigative components:

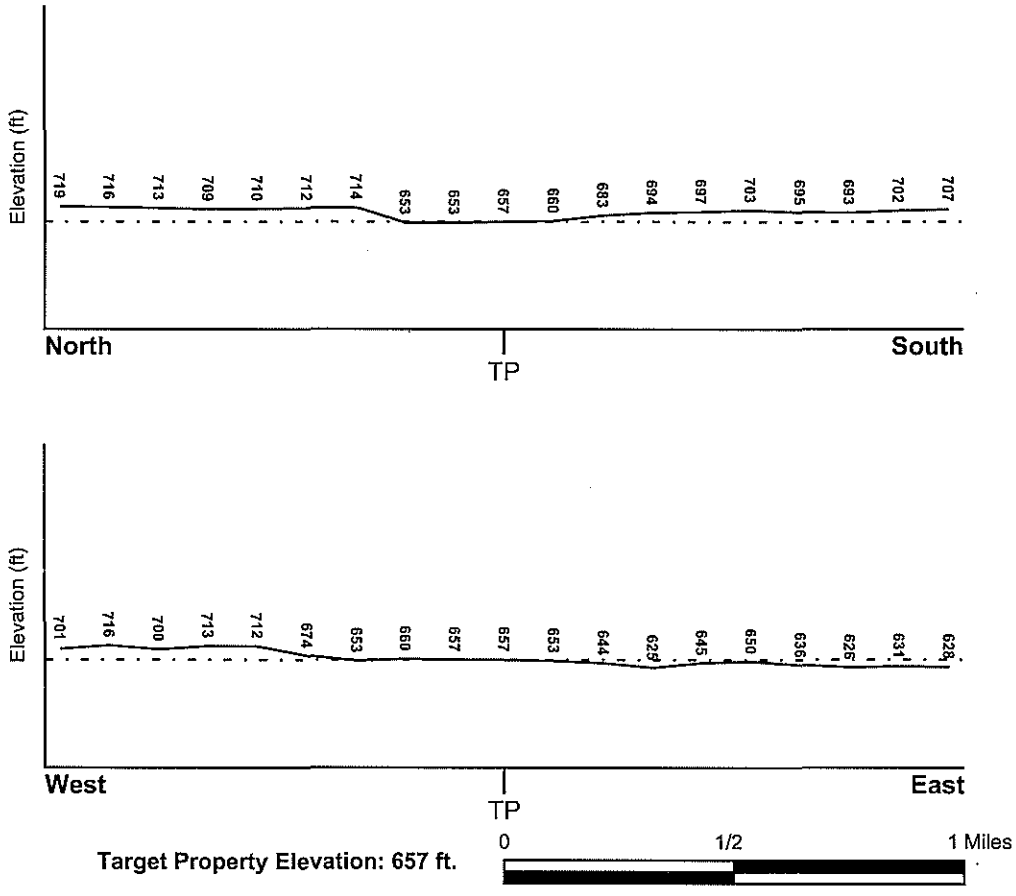
1. Groundwater flow direction, and
2. Groundwater flow velocity.

Groundwater flow direction may be impacted by surface topography, hydrology, hydrogeology, characteristics of the soil, and nearby wells. Groundwater flow velocity is generally impacted by the nature of the geologic strata.

GEOCHECK® - PHYSICAL SETTING SOURCE SUMMARY

GROUNDWATER FLOW DIRECTION INFORMATION

Groundwater flow direction for a particular site is best determined by a qualified environmental professional using site-specific well data. If such data is not reasonably ascertainable, it may be necessary to rely on other sources of information, such as surface topographic information, hydrologic information, hydrogeologic data collected on nearby properties, and regional groundwater flow information (from deep aquifers).



TOPOGRAPHIC INFORMATION

Surface topography may be indicative of the direction of surficial groundwater flow. This information can be used to assist the environmental professional in forming an opinion about the impact of nearby contaminated properties or, should contamination exist on the target property, what downgradient sites might be impacted.

TARGET PROPERTY TOPOGRAPHY

General Topographic Gradient: General ENE

SURROUNDING TOPOGRAPHY: ELEVATION PROFILES

Source: Topography has been determined from the USGS 7.5' Digital Elevation Model and should be evaluated on a relative (not an absolute) basis. Relative elevation information between sites of close proximity should be field verified.

GEOCHECK® - PHYSICAL SETTING SOURCE SUMMARY

HYDROLOGIC INFORMATION

Surface water can act as a hydrologic barrier to groundwater flow. Such hydrologic information can be used to assist the environmental professional in forming an opinion about the impact of nearby contaminated properties or, should contamination exist on the target property, what downgradient sites might be impacted.

Refer to the Physical Setting Source Map following this summary for hydrologic information (major waterways and bodies of water).

HYDROGEOLOGIC INFORMATION

Hydrogeologic information obtained by installation of wells on a specific site can often be an indicator of groundwater flow direction in the immediate area. Such hydrogeologic information can be used to assist the environmental professional in forming an opinion about the impact of nearby contaminated properties or, should contamination exist on the target property, what downgradient sites might be impacted.

Site-Specific Hydrogeological Data*:

Search Radius:	1.25 miles
Status:	Not found

AQUIFLOW®

Search Radius: 1.000 Mile.

EDR has developed the AQUIFLOW Information System to provide data on the general direction of groundwater flow at specific points. EDR has reviewed reports submitted by environmental professionals to regulatory authorities at select sites and has extracted the date of the report, groundwater flow direction as determined hydrogeologically, and the depth to water table.

All of the information and opinions presented are those of the cited EPA report(s), which were completed under a Comprehensive Environmental Response Compensation and Liability Information System (CERCLIS) investigation.

GEOCHECK® - PHYSICAL SETTING SOURCE SUMMARY

GROUNDWATER FLOW VELOCITY INFORMATION

Groundwater flow velocity information for a particular site is best determined by a qualified environmental professional using site specific geologic and soil strata data. If such data are not reasonably ascertainable, it may be necessary to rely on other sources of information, including geologic age identification, rock stratigraphic unit and soil characteristics data collected on nearby properties and regional soil information. In general, contaminant plumes move more quickly through sandy-gravelly types of soils than silty-clayey types of soils.

GEOLOGIC INFORMATION IN GENERAL AREA OF TARGET PROPERTY

Geologic information can be used by the environmental professional in forming an opinion about the relative speed at which contaminant migration may be occurring.

ROCK STRATIGRAPHIC UNIT

GEOCHECK® - PHYSICAL SETTING SOURCE SUMMARY

DOMINANT SOIL COMPOSITION IN GENERAL AREA OF TARGET PROPERTY

The U.S. Department of Agriculture's (USDA) Soil Conservation Service (SCS) leads the National Cooperative Soil Survey (NCSS) and is responsible for collecting, storing, maintaining and distributing soil survey information for privately owned lands in the United States. A soil map in a soil survey is a representation of soil patterns in a landscape. The following information is based on Soil Conservation Service SSURGO data.

Soil Map ID: 1

Soil Component Name: Udorthents

Soil Surface Texture: variable

Hydrologic Group: Class B - Moderate infiltration rates. Deep and moderately deep, moderately well and well drained soils with moderately coarse textures.

Soil Drainage Class: Somewhat excessively drained

Hydric Status: Not hydric

Corrosion Potential - Uncoated Steel: Moderate

Depth to Bedrock Min: > 0 inches

Depth to Watertable Min: > 0 inches

Soil Layer Information							
	Boundary			Classification		Saturated hydraulic conductivity micro m/sec	Soil Reaction (pH)
Layer	Upper	Lower	Soil Texture Class	AASHTO Group	Unified Soil		
1	0 inches	59 inches	variable	Not reported	Not reported	Max: 42 Min: 0	Max: Min:

Soil Map ID: 2

Soil Component Name: Water

Soil Surface Texture: variable

Hydrologic Group: Class B - Moderate infiltration rates. Deep and moderately deep, moderately well and well drained soils with moderately coarse textures.

Soil Drainage Class:
Hydric Status: Unknown

Corrosion Potential - Uncoated Steel: Not Reported

Depth to Bedrock Min: > 0 inches

Depth to Watertable Min: > 0 inches

No Layer Information available.

GEOCHECK® - PHYSICAL SETTING SOURCE SUMMARY

Soil Map ID: 3

Soil Component Name: Kewaunee

Soil Surface Texture: silty clay loam

Hydrologic Group: Class C - Slow infiltration rates. Soils with layers impeding downward movement of water, or soils with moderately fine or fine textures.

Soil Drainage Class: Well drained

Hydric Status: Not hydric

Corrosion Potential - Uncoated Steel: High

Depth to Bedrock Min: > 0 inches

Depth to Watertable Min: > 0 inches

Soil Layer Information							
	Boundary			Classification		Saturated hydraulic conductivity micro m/sec	Soil Reaction (pH)
Layer	Upper	Lower	Soil Texture Class	AASHTO Group	Unified Soil		
1	0 inches	5 inches	silty clay loam	Not reported	Not reported	Max: 4 Min: 0	Max: 8.4 Min: 7.4
2	5 inches	27 inches	clay	Not reported	Not reported	Max: 4 Min: 0	Max: 8.4 Min: 7.4
3	27 inches	59 inches	silty clay	Not reported	Not reported	Max: 4 Min: 0	Max: 8.4 Min: 7.4

Soil Map ID: 4

Soil Component Name: Briggsville

Soil Surface Texture: silt loam

Hydrologic Group: Class C - Slow infiltration rates. Soils with layers impeding downward movement of water, or soils with moderately fine or fine textures.

Soil Drainage Class: Well drained

Hydric Status: Not hydric

Corrosion Potential - Uncoated Steel: High

Depth to Bedrock Min: > 0 inches

Depth to Watertable Min: > 0 inches

GEOCHECK® - PHYSICAL SETTING SOURCE SUMMARY

Soil Layer Information							
	Boundary			Classification		Saturated hydraulic conductivity micro m/sec	Soil Reaction (pH)

GEOCHECK® - PHYSICAL SETTING SOURCE SUMMARY

Soil Map ID: 6

Soil Component Name: Nichols

Soil Surface Texture: very fine sandy loam

Hydrologic Group: Class B - Moderate infiltration rates. Deep and moderately deep, moderately well and well drained soils with moderately coarse textures.

Soil Drainage Class: Moderately well drained

Hydric Status: Not hydric

Corrosion Potential - Uncoated Steel: Low

Depth to Bedrock Min: > 0 inches

Depth to Watertable Min: > 137 inches

Soil Layer Information							
	Boundary			Classification		Saturated hydraulic conductivity micro m/sec	Soil Reaction (pH)
Layer	Upper	Lower	Soil Texture Class	AASHTO Group	Unified Soil		
1	0 inches	9 inches	very fine sandy loam	Not reported	Not reported	Max: 14 Min: 4	Max: 8.4 Min: 7.4
2	9 inches	25 inches	loamy sand	Not reported	Not reported	Max: 14 Min: 4	Max: 8.4 Min: 7.4
3	25 inches	59 inches	stratified fine sand to silt	Not reported	Not reported	Max: 14 Min: 4	Max: 8.4 Min: 7.4

Soil Map ID: 7

Soil Component Name: Kaukauna

Soil Surface Texture: silty clay loam

Hydrologic Group: Class C - Slow infiltration rates. Soils with layers impeding downward movement of water, or soils with moderately fine or fine textures.

Soil Drainage Class: Moderately well drained

Hydric Status: Not hydric

Corrosion Potential - Uncoated Steel: High

Depth to Bedrock Min: > 0 inches

Depth to Watertable Min: > 137 inches

GEOCHECK® - PHYSICAL SETTING SOURCE SUMMARY

Soil Layer Information							
	Boundary			Classification		Saturated hydraulic conductivity micro m/sec	Soil Reaction (pH)

PHYSICAL SETTING SOURCE RECORDS SEARCHED

TOPOGRAPHIC INFORMATION

USGS 7.5' Digital Elevation Model (DEM)
Source: United States Geologic Survey
EDR acquired the USGS 7.5' Digital Elevation Model in 2002 and updated it in 2006. The 7.5 minute DEM corresponds to the USGS 1:24,000- and 1:25,000-scale topographic quadrangle maps. The DEM provides elevation data with consistent elevation units and projection.

Scanned Digital USGS 7.5' Topographic Map (DRG)
Source: United States Geologic Survey
A digital raster graphic (DRG) is a scanned image of a U.S. Geological Survey topographic map. The map images are made by scanning published paper maps on high-resolution scanners. The raster image is georeferenced and fit to the Universal Transverse Mercator (UTM) projection.

HYDROLOGIC INFORMATION

Flood Zone Data: This data, available in select counties across the country, was obtained by EDR in 1999 from the Federal Emergency Management Agency (FEMA). Data depicts 100-year and 500-year flood zones as defined by FEMA.

NWI: National Wetlands Inventory. This data, available in select counties across the country, was obtained by EDR in 2002 and 2005 from the U.S. Fish and Wildlife Service.

HYDROGEOLOGIC INFORMATION

AQUIFLOW^{R} Information System
Source: EDR proprietary database of groundwater flow information
EDR has developed the AQUIFLOW Information System (AIS) to provide data on the general direction of groundwater flow at specific points. EDR has reviewed reports submitted to regulatory authorities at select sites and has extracted the date of the report, hydrogeologically determined groundwater flow direction and depth to water table information.

GEOLOGIC INFORMATION

Geologic Age and Rock Stratigraphic Unit
Source: P.G. Schruben, R.E. Arndt and W.J. Bawiec, Geology of the Conterminous U.S. at 1:2,500,000 Scale - A digital representation of the 1974 P.B. King and H.M. Beikman Map, USGS Digital Data Series DDS - 11 (1994).

STATSGO: State Soil Geographic Database
Source: Department of Agriculture, Natural Resources Conservation Services
The U.S. Department of Agriculture's (USDA) Natural Resources Conservation Service (NRCS) leads the national Conservation Soil Survey (NCSS) and is responsible for collecting, storing, maintaining and distributing soil survey information for privately owned lands in the United States. A soil map in a soil survey is a representation of soil patterns in a landscape. Soil maps for STATSGO are compiled by generalizing more detailed (SSURGO) soil survey maps.

SSURGO: Soil Survey Geographic Database
Source: Department of Agriculture, Natural Resources Conservation Services (NRCS)
Telephone: 800-672-5559
SSURGO is the most detailed level of mapping done by the Natural Resources Conservation Services, mapping scales generally range from 1:12,000 to 1:63,360. Field mapping methods using national standards are used to construct the soil maps in the Soil Survey Geographic (SSURGO) database. SSURGO digitizing duplicates the original soil survey maps. This level of mapping is designed for use by landowners, townships and county natural resource planning and management.

Telephone: 202-564-3750
Public Water System data from the Federal Reporting Data System. A PWS is any water system which provides water to at least 25 people for at least 60 days annually. PWSs provide water from wells, rivers and other sources.

PWS ENF: Public Water Systems Violation and Enforcement Data
Source: EPA/Office of Drinking Water
Telephone: 202-564-3750
Violation and Enforcement data for Public Water Systems from the Safe Drinking Water Information System (SDWIS) after August 1995. Prior to August 1995, the data came from the Federal Reporting Data System (FRDS).

USGS Water Wells: USGS National Water Inventory System (NWIS)
This database contains descriptive information on sites where the USGS collects or has collected data on surface water and/or groundwater. The groundwater data includes information on wells, springs, and other sources of groundwater.

STATE RECORDS

Wisconsin Well Construction Report File
Source: Department of Natural Resources
Telephone: 608-266-0153
In the past, not all latitude/longitudes were accurate. Many were protracted from centroid (center of the quarter sections given in PLSS). The ones that were not accurate were removed from the well database.

2009 Enhancements to EDR City Directory Abstract

New for 2009, the EDR City Directory Abstract has been enhanced with additional information and features. These enhancements will make your city directory research process more efficient, flexible, and insightful than ever before. The enhancements will improve the options for selecting adjoining properties, and will speed up your review of the report.

City Directory Report. Three important enhancements have been made to the EDR City Directory Abstract:

1. *Executive Summary.* The report begins with an Executive Summary that lists the sources consulted in the preparation of the report. Where available, a parcel map is also provided within the report, showing the locations of properties researched.

2. *Page Images.* Where available, the actual page source images will be included in the Appendix, so that you can review them for information that may provide additional insight. EDR has copyright permission to include these images.

3. *Findings Listed by Location.* Another useful enhancement is that findings are now grouped by address. This will significantly reduce the time you need to review your abstracts. Findings are provided under each property address, listed in reverse chronological order and referencing the source for each entry.

Options for Selecting Adjoining Properties. Ensuring that the right adjoining property addresses are searched is one of the biggest challenges that environmental professionals face when conducting city directory historical research. EDR's new enhancements make it easier for you to meet this challenge. Now, when you place an order for the EDR City Directory Abstract, you have the following choices for determining which addresses should be researched.

1. *You Select Addresses and EDR Selects Addresses.* Use the "Add Another Address" feature to specify the addresses you want researched. Your selections will be supplemented by addresses selected by EDR researchers using our established research methods. Where available, a digital map will be shown, indicating property lines overlaid on a color aerial photo and their corresponding addresses. Simply use the address list below the map to check off which properties shown on the map you want to include. You may also select other addresses using the "Add Another Address" feature at the bottom of the list.

2. *EDR Selects Addresses.* Choose this method if you want EDR's researchers to select the addresses to be researched for you, using our established research methods.

3. *You Select Addresses.* Use this method for research based solely on the addresses you select or enter into the system.

4. *Hold City Directory Research Option.* If you choose to select your own adjoining addresses, you may pause production of your EDR City Directory Abstract report until you have had a chance to look at your other EDR reports and sources. Sources for property addresses include: your Certified Sanborn Map Report may show you the location of property addresses; the new EDR Property Tax Map Report may show the location of property addresses; and your field research can supplement these sources with additional address information. To use this capability, simply click "Hold City Directory research" box under "Other Options" at the bottom of the page. Once you have determined what addresses you want researched, go to your EDR Order Status page, select the EDR City Directory Abstract, and enter the addresses and submit for production.

Questions? Contact your EDR representative at 800-352-0050. For more information about all of EDR's 2009 report and service enhancements, visit www.edrnet.com/2009enhancements

EXECUTIVE SUMMARY

DESCRIPTION

Environmental Data Resources, Inc.'s (EDR) City Directory Abstract is a screening tool designed to assist environmental professionals in evaluating potential liability on a target property resulting from past activities. EDR's City Directory Abstract includes a search and abstract of available city directory data. For each address, the directory lists the name of the corresponding occupant at five year intervals.

RESEARCH SUMMARY

The following research sources were consulted in the preparation of this report. An "X" indicates where information was identified in the source and provided in this report.

ANTHONY MUELLER, P.E.

SENIOR PRINCIPAL

OVERVIEW

Mr. Mueller has over 20 years of experience in the consulting and due diligence industry. His varied experience has contributed to a broad understanding of real estate issues, especially as they pertain to the significance of environmental and engineering concerns. After opening a European office to service agreements with the U.S. Department of Defense, Mr. Mueller became involved in the emerging real estate due diligence industry. Since the mid 1990s, Mr. Mueller has worked with clients to conduct and manage Environmental, Property Condition and Seismic Assessments, encompassing a wide variety of properties.

ENVIRONMENTAL ASSESSMENT	Mr. Mueller has performed and/or managed thousands of Phase I and II Environmental Assessments for public entities and for major lending institutions and investors and has acted as a key advisor for Agency and CMBS clients securing properties valued at well over $100,000,000.
PROPERTY CONDITION ASSESSMENT	Utilized engineering background and knowledge of building systems to conduct and/or manage thousands of Property Condition Surveys for lenders, developers and/or investors.

EXPERIENCE

LANDAMERICA ASSESSMENT CORPORATION

National Client Manager

Responsible for direct relationships with select national and local clients. Key roles included:

- Expanding company revenue by increasing sales of assessment services to existing and new clients.
- Customer support utilizing technical background applied to various areas of due diligence services, including, but not limited to, commercial construction process, engineering assessments, and environmental risk assessments.
- Serviced broad range of lenders, including CMBS, Agency, Life Insurance Companies, Bank, and Mortgage Banking community.
- Managed due diligence for Equity players, including buyers, investors, and sale/leaseback firms.
- Promoted cross-selling of non-core services, including appraisal, title, and cost segregation.

AARON & WRIGHT TECHNICAL SERVICES

Director of Technical Services

Managed a regional office and book of national clients for this Houston-based due diligence firm. Key accomplishments include:

- Expansion of client base regionally and nationally.
- Developed service offerings specific to CMBS, Agency, Life Insurance Companies, Bank, Equity, and Mortgage Banking clients.
- Recruited field personnel to establish a national footprint in service

coverage.

- Developed firm's report products and implemented quality control metrics from 1996 – 2004.

AFFILIATIONS

Member, Chicago Real Estate Council

EDUCATION AND CERTIFICATIONS

- Bachelor of Science, Mechanical Engineering, University of Illinois – Chicago
- Professional Engineer - Illinois, Indiana

REPRESENTATIVE SPEAKING ENGAGEMENTS

- Introduction to Environmental Assessments and ASTM/AAI, National Life Company, Chicago
- Introduction to Environmental and Property Condition Assessments, National CMBS Lender, Chicago and New York

ENVIRONMENTAL SITE ASSESSMENT QUESTIONNAIRE

Please complete to the best of your knowledge. For those questions that are not applicable, please respond with an "N/A". For those questions that are unknown, please respond with "unknown".

1. PROPERTY INFORMATION:

Property Name: Fox Shores Apartments		
Property Address: 400 Fox Shores Drive		
City Kaukauna	State Wisconsin	Zip 54130
Assessor's Parcel Number See Attached		
Property Owner & Contact Information: Thomas Vandeyacht Office: (920)380-9631; Cell:(920)213-7145; Email: tomv@vmi-vdi.com		
Date Property Owner Purchased: June, 1998		
Key Site Manager & Contact Information: Thomas Vandeyacht		
Maintenance Supervisor & Contact Information: Thomas Vandeyacht (920)213-7145		

2. COMPLETED BY

Signature	Date 6/11/2018
Printed Name Thomas Vandeyacht	Relation to Subject Property Owner

3. PREVIOUS INVESTIGATIONS

Have any previous environmental investigations been performed at the property, including Phase I ESAs, Phase II Subsurface Investigations, Remediation, Asbestos or Lead-Based Paint surveys?__

Yes, Phase I environmental site assessment

(If yes, please provide copies)

4. PROPERTY DESCRIPTION

Property Size: __2.815 Acres +/-_____ Number of Building(s): __6 Multi Family, 4 Garage,____

Number and Type of Unit(s):___32 2-bed, 1-bath; 24 2-bed, 2-bath_

Number of ground floor units: 28

Size of Building(s): *(SF and amount of floors, 1, 2, etc)*__Two Waterfront Buildings are 14,400 Sq.Ft. on two floors, four Off Water Buildings are 7,456 Sq.Ft., on two floors

Date of Construction: __1983-1991

Date of Addition(s) / Renovation(s): _____

Property Type: (please circle)

Multi-Family Hotel Mobile Home Park Retail/Commercial Industrial Office Other:_____

If **Pre-1978**, are Lead Pamphlets (***EPA Protect Your Family from in Your Home Guide)*** being handed out to tenants?

Historical Use of Property: Rail Road Tracks

5. **SURROUNDING PROPERTY USES** (*Include Roadways*)

DIRECTION	USE
North	**FOX RIVER**
South	**COMMERCIAL**
East	**COMMERCIAL**
West	**MULTIFAMILY**

Are you aware of any potential environmental concerns associated with surrounding properties?

_____ YES ___X___NO

If yes, please describe: _____

_____

6. UTILITIES & SERVICES

Please provide the name of the utility or contractor providing the following:

Electric	Kaukauna Power & Light	Bio-hazardous Waste	_____
Gas	NA	Elevator Maintenance	_____
Potable Water	Kaukauna Utilities	Used Grease	_____
Sanitary Sewer	Kaukauna Utilities	Hazardous Waste	_____
Solid Waste	Van's Waste	Medical Waste	_____

Other contractor provided service(s): _____

7. ON SITE OPERATIONS

Are you aware of any of the following conditions, either past or present, on the property?		
Condition	**Response**	**If yes, please describe**
1. Water-damaged areas	☐ Yes X No	
2. Suspect / Confirmed Mold-affected areas	☐ Yes X No	
3. Stored Chemicals	X Yes ☐ No	General Use and Cleaning
4. Underground Storage Tanks	☐ Yes X No	
5. Aboveground Storage Tanks ➢ (Include Emergency Generators)	☐ Yes X No	

➢ Propane Tanks		
6. PROPOSED Stationary tanks, which includes aboveground storage tanks including emergency generators, propane tanks, etc. **100 gallons or larger**	☐ **Yes X No**	
7. Spills or Releases *(greater than 5-gallons)*	☐ Yes X No	
8. Dump Areas / Landfills	☐ Yes X No	
9. Waste Treatment Systems	☐ Yes X No	
10. Clarifiers / Separators	☐ Yes X No	
11. Vents / Odors	☐ Yes X No	
12. Floor Drains / Sumps	X Yes ☐ No	General Use
13. Stained Soil	☐ Yes X No	
14. Electrical Transformers ➢ Pad-mounted / Pole-mounted	X Yes ☐ No	Kaukauna Power Transformers
15. Hydraulic Lifts / Elevators	☐ Yes X No	
16. Dry Cleaning Operations	☐ Yes X No	
17. Oil / Gas / Water / Monitoring Wells	☐ Yes X No	
18. Water Supply Wells	☐ Yes X No	One well for irrigation
19. Environmental Permits	☐ Yes X No	
20. Abatement Activities ➢ Asbestos/Lead/Mold ➢ Water/Fire Restoration	☐ Yes X No	
21. Mitigation Activities ➢ Radon / Subsurface cleanup ➢ Vapor Intrusion *(i.e. Methane)*	☐ Yes X No	
22. Marketability / Noise Concerns ➢ Have noise issues created a marketability issue at the property?	☐ Yes X No	*If so, why (road, rail, air, etc)*
23. Marketability ➢ What percentage has the occupancy rate been since the original date of construction?	96-99 %	*(If occupancy rate since original date of construction is unknown, list the occupancy rates for known dates, ie. 85% between 1985 and present)*

8. REPORTS REQUESTED:

- If Lead Pamphlets handed out to tenants obtain copy of ***EPA Protect Your Family from in Your Home Guide***
- Rent Roll
- Site Layout Map / Brochure
- Previous Environmental Reports, including, but not limited to:

    - ESAs,
    - Asbestos/Lead-Based Paint Surveys,
    - Mold Inspections,
    - Water Supply Well Testing Reports
- Haz-Waste manifests, including, but not limited to: (most recent) Bio-hazard manifest, waste grease (food-grade)
- Additional reports regarding environmental issues.

Surveyor's Certificate

I, James R. Sehloff, registered land surveyor, hereby certify: That in full compliance with the provisions of Chapter 236 of the Wisconsin Statutes and the subdivision regulations of the City of Kaukauna and Outagamie County, and under the direction of Fox Investments LLC and Thomas R. Vandeyacht & Mary K. Vandeyacht, the property owners of said land, I have surveyed divided and mapped this Certified Survey Map; that such map correctly represents all exterior boundaries and the subdivision of the land surveyed; and that this land is part of Parcel 3, Certified Survey Map #59 located in the City of Kaukauna, Outagamie County, Wisconsin, containing 78,026 Square Feet (1.7913 Acres) of land described as follows:

Beginning at the Northeast corner of Lot 1, Certified Survey Map 155, thence S85°57'40"E, 198.79 feet; thence N86°57'10"E, 133.96 feet; thence S74°37'20"E 17.30 feet; thence S21°00'15"E, 271.79 feet; thence S27°56'50"E, 52.82 feet to the Northeast corner of Lot 1, Certified Survey Map 348; thence along the North line of said Lot 1 N82°43'55"W, 103.20 feet to a point of the Northeasterly right of way of Fox Shores Dr.; thence along the northerly right of way line of said Fox Shores Dr., N54°25'50"W 160.00 feet; thence 235.21 feet along and arc of a curve to the left with a radius of 50.00 feet and a chord which bears S80°34'10"W, 71.00 feet to the East corner of Lot 1, Certified Survey Map 307; thence along the Northerly line of said Lot 1, N54°25'50"W 110.00 feet; thence continuing along said Northerly line, N79°54'30"W 104.54 feet to a point on the East line of said Lot 1 Certified Survey Map 155; thence along said East line, N10°05'30"E 137.19 feet to the point of beginning, subject to all easements and restrictions of record.

Given under my hand this 21 day of APRIL, 2010.

BUILDING & ZONING VIOLATIONS/RECORDS REQUEST

Partner Engineering and Science, Inc. is conducting a Phase I Environmental Site Assessment and/or a Property Condition Report Assessment on the following property:

Fox Shores Apartments
400 Fox Shores Drive
Kaukauna, Wisconsin 54130
Partner Project 215232.1

As part of the investigation, we are requesting informally any and all records you have for the above-referenced property pertaining to the following:

a. Current Zoning Designation is:_____
b. The CURRENT USE at the property is permitted in this zoning designation. Yes No
c. Conditional uses established for the property (if any):_____ None

- Please send copies of any unresolved Notices of Violation or Notices to Comply documents filed against the property.
  ____Yes, copies included ____None on record
- How frequently is the property inspected by the Building Department?
  ___During Construction ___To investigate a complaint ___Annually

  ___Never ___Other [please describe] _____

- Date of last inspection:_____ [Please provide a copy, as available.]

- Please send copies of any open building department permits. ___Yes, copies included ___None in records

- Please send copies of the Certificates of Occupancy.

- Please send copies of permits for any current or historic USTs/ASTs.

Please forward any records that exist for the aforementioned property or any other pertinent information, at your earliest convenience. Also, please notify Partner if there are any costs associated with this request prior to processing.

Also, please respond to this email stating whether you received it and/or the approximate date we will have these records, it is very imperative.

VIOLATIONS/RECORDS REQUEST

Partner Engineering and Science, Inc. is conducting a Phase I Environmental Site Assessment and/or a Property Condition Report Assessment on the following property:

Fox Shores Apartments
400 Fox Shores Drive
Kaukauna, Wisconsin 54130
Partner Project 215232.1

As part of the investigation, we are requesting, under the Freedom of Information Act, any zoning, building, fire, or environmental health records you have for the above-referenced property pertaining to the following:

- current zoning designation, if the current use is permitted, and conditional uses (if any)
- any unresolved notices of violation/to comply, date of last inspection by the building department, copies of any open building department permits, copies of certificates of occupancy, copies of permits and records for any current or historic storage tanks
- hazardous materials incidents, fire inspection records, outstanding fire code violations
- records of asbestos or lead-based paint, septic system and water well information, human health concerns

Please forward any records that exist for the aforementioned property or any other pertinent information, at your earliest convenience. Also, please notify Partner if there are any costs associated with this request prior to processing. Also, please respond to this email stating whether you received it and/or the approximate date we will have these records, it is very imperative.

Subject: RE: 18ORR5941: Fox Shores Apartments, 400 Fox Shores Drive, Kaukauna

Hi Rose,

In response to your open records request, submitted on June 15, 2018, the department has searched for records pertaining to Fox Shores Apartments, 400 Fox Shores Drive, Kaukauna, WI and the following:

- Current of historical use of hazardous materials and/or hazardous waste
- Groundwater monitoring wells
- Current or historical clarifiers, oil/water separators, grease traps, interceptors
- Incidents of lead or asbestos, fires, leaks [USTs/ASTs] and spills
- Code Violations or Notices to Comply

The Wisconsin Department of Natural Resources has concluded its search and located no records responsive to your request. The open records request will be closed. Please let me know if you have any questions.

Sincerely,

We are committed to service excellence.
Visit our survey at http://dnr.wi.gov/customersurvey to evaluate how I did.

Partner Engineering and Science, Inc. (Partner), a National Real Estate Due Diligence Firm, is conducting a Property Capital Needs Assessment and/or an Environmental Site Assessment for the above-referenced site(s) on behalf of a financial services client. These assessments are being conducted in accordance with rules and regulations of conventional Freedom of Information Act provisions. Therefore, we are requesting the following information to include in our reports:

- Are there any unresolved Notices of Violation or Notices to Comply documents filed against the property?
  ____Yes ____No [If Yes, please provide details on an attached sheet.]
- How frequently is the property inspected by the Fire Department/Fire Marshal?
  ___During Construction ___To investigate a complaint ___Annually
  ___Never ___Other [please describe] _____
- Date of last inspection:_____
  [Please provide a copy, as available.]
- Are there any current records related to the following: ___Yes ___No
  [If Yes, please provide details on an attached sheet.]
  a. Current or historical use of hazardous materials/waste
  b. Storage or release of hazardous materials/waste
  c. Current or historical underground/aboveground storage tanks [USTs/ASTs]
  d. Current or historic clarifiers
  e. Any HAZMAT responses to the property
  [Please provide copies, as available.]

Additionally (if applicable), please provide information/certification that the sprinkler system is in compliance with the 1999 Edition of the National Fire Protection Association's (NFPA) "Standard for the Installation of Sprinkler Systems" (NFPA 13), and the 1998 edition of the NFPA "Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems" (NFPA 25).

APPENDIX D: QUALIFICATIONS

PARTNER

Education

Bachelor of Science, Civil Engineering, Manhattan College, 1990
Associates Degree, Civil Technology, SUNY Delhi, 1986

Registrations

Engineer in Training Certificate (E.I.T)
HUD MAP and LEAN Certification

Training

HUD MAP and LEAN Certification
Fannie Mae

Highlights

20 years of professional commercial real estate due diligence related experience
Property Condition Assessments (PCAs), Including Equity Scope on all property types
HUD MAP and LEAN Property Condition Needs Assessments (PCNAs)
Fannie Mae and Freddie Mac Physical Needs Assessments (PNAs)
Construction Document Plan and Cost Reviews

Experience Summary

Mr. Hetner is a Senior Assessor for Partner Engineering and Science, Inc. (Partner). His responsibilities include conducting equity scope PCAs for real estate investors on all property types and HUD MAP and LEAN PNAs. Mr. Hetner provides support and training for Partner's Chicago staff. Mr. Hetner has performed hundreds of Property Condition Assessments (PCA) at projects located throughout the US, managed thousands of PCAs and related due diligence reports, dozens of Phase I ESA surveys, over fifty HUD MAP and LEAN PCNAs, and performed over one hundred construction monitoring site visits. Mr. Hetner has also provided many specialty services such as, Construction Plan and Cost Reviews, Property Improvement Plan (PIP) reviews and cost estimates for hotels, equity scope PCAs, multi-family property management, and Fannie Mae and Freddie Mac PNAs.

Prior to entering the commercial real estate due diligence field Mr. Hetner was a structural engineer for a large international engineering company located in New York City and was a Civil Engineer for a mid-sized company located in Long Island, New York.

Project Experience

Spring Creek Apartments, Brooklyn, New York. Conducted a Freddie Mac Scope PCA of the Spring Creek apartment complex a 5,881 unit complex with its own on-site 18-megawatt power plant. The property, valued at over $1.0 billion, was the largest deal in Freddie Mac history.

Thompson Center State Office Building, Chicago, Illinois. Conducted a PCA of the Thompson Center, an approximately 1.8 million square feet, state office tower located in Chicago's central Loop District. The building, a Chicago landmark, features an interior 17-story atrium with 13 floors of balconies overlooking a central rotunda. The building utilizes a thermal storage system for cooling.

Trump/GM Building, New York City, New York. Conducted a PCA of the Trump/GM Building, a 1.8 million square foot, 50-story tower located in midtown Manhattan. The property was valued at over $1.0 billion at the time of the assessment.

Museum Park East and Museum Park Place South, Chicago, Illinois. Performed and managed equity scope PCAs with Reserve Studies for 53-story and 30-story luxury condominium tower properties located in Chicago's South Loop. Served as the generalist engineer while coordinating and managing a team of specialists including façade; roof; elevator; structural; and mechanical, electrical and plumbing (MEP) experts. Compiled the findings and Immediate Repair and Replacement Reserves cost details into comprehensive PCA reports for both properties. The scope of work included Mr. Hetner's development of 20-year reserve budgets for the condominium associations to ensure that condo owner assessment levels were set at consistent levels and were sufficient to cover projected immediate and future repair and maintenance.

Fixed Based Operator (FBO) Buildings, Detroit Metropolitan Airport, Romulus, Michigan. Performed equity scope PCAs for two FBO hangar buildings located within Detroit Metropolitan Airport. Served as the generalist engineer and compiled the findings and Immediate Repair and Replacement Reserves cost details into comprehensive PCA reports for both properties.

Marshall Field Garden Apartments, Chicago, Illinois. Performed a Physical Needs Assessment (Fannie Mae Scope) of a 10 building, 628 unit apartment complex. The complex was constructed in 1929 and is listed on the National Register of Historic Places.

Key Center, Cleveland, Ohio. Performed an equity scope PCA of the Key Center, a mixed-use (office/hotel/parking) complex located in Downtown Cleveland. The complex consists of the 63-story (947 foot tall), 1.39 million square foot Key Center Tower (tallest building between New York City and Chicago); a 27-story full service 400 room Marriott Hotel; a 10-story historical office building constructed in 1890; and, a 982 space parking garage situated below a public plaza.

Willis Tower (formerly Sears Tower), Chicago, Illinois. Performed and managed an equity scope PCA of the iconic 110-story (1,450 foot tall), 4.15 million gross square foot tower. Served as a generalist engineer while coordinating and managing a team of specialists including façade; roof; elevator; structural; fire/life safety; and mechanical, electrical and plumbing (MEP) experts. Acted as liaison between all specialists and Willis Tower staff to ensure timely access was provided and scope requirements were being met. Assisted Partner Equity PCA staff with compiling the findings and Immediate Repair and Replacement Reserves cost details into a comprehensive PCA report.

Education

B.S., Fisheries and Wildlife Sciences; Aquatic Track, University of Missouri

Highlights

5 years of experience performing environmental due diligence assessments
3 years of experience performing environmental assessments for agencies such as HUD, Fannie Mae, SBA
3 years of completing Property Condition Assessments
2 years of experience performing specialized scope assessments for the oil and gas industry
2 years of experience working alongside the Missouri Department of Conservation and United States Fish and Wildlife Service

Experience Summary

Mr. Chiu is a Project Manager for Partner Engineering and Science, Inc. (Partner). In his role of Project Manager, Mr. Chiu is responsible for performing Phase I Environmental Site Assessments (ESA), Property Condition Assessments (PCA), Naturally Occurring Radioactive Material (NORM) Surveys and Exit Audits in line with the American Society of Testing and Materials (ASTM) standard and US Environmental Protection Agency's All Appropriate Inquiry (AAI) as well as customized client formats. Mr. Chiu's responsibilities as a Project Manager also include reviewing Phase I ESAs and PCAs, and include supervision of in-house and contracted staff, overall responsibility of project scope/design, and the project and task implementation/execution.

Project Management

Mr. Chiu has managed and reviewed projects for multiple National Client Managers. Clients served include equity-level investors, national and regional banks, life insurance companies, mortgage lending agencies and non-profit organizations. Mr. Chiu's daily responsibilities include identifying qualified assessors for various projects, reviewing ESA and PCA reports, and managing site-specific questions clients may have during the course of an assessment. Additionally, Mr. Chiu is responsible for managing project budgets and maintaining profitability for multiple National Client Managers.

Field Work

Prior to working as a Project Manager, Mr. Chiu completed over 400 projects located throughout Texas as well as 17 other states in the country. Mr. Chiu worked closely with state and local regulatory agencies to obtain environmentally significant documents regarding tank removal and subsurface investigations performed onsite. Mr. Chiu has worked for large financial institutions as well as private investors and has also performed work for the Federal Deposit Insurance Corporation, United States Department of Housing and Urban Development, Fannie Mae, and Small Business Administration. Mr. Chiu has also completed Property Condition Assessments for three years for various commercial, industrial, medical, and multi-family properties.

Previous Work

Mr. Chiu served as a project leader for an environmental analysis of a 322-acre former mining site owned by the Missouri Department of Conservation. His team's remediation proposal was ultimately reviewed by various state agencies for submission. Mr. Chiu has conducted numerous multi-parameter limnological and groundwater surveys at across the state of Missouri at sites such as Rocky Forks Conservation Area, Eagle

Bluffs Conservation Area Finger Lakes State Park and Little Dixie State Park and Recreation area. He also has experience working with federal agencies such as the U.S. Fish and Wildlife Service. He worked alongside U.S. Fish and Wildlife professionals sampling the Missouri River for an endangered aquatic species.

Project Experience

Industrial

Heavy Industrial Shipping Port, Houston, TX. Mr. Chiu managed the Phase I Environmental Site assessment of a 600-acre heavy industrial shipping port that included numerous tenants, railroad switch-yards, and deep-water shipping channels. Mr. Chiu worked closely with onsite personnel and state regulatory agencies to identify areas of concern, permitting needs, and historic operations across the property.

Industrial Plating Facility, Royse City, TX. Mr. Chiu performed a Phase I Environmental Site Assessment on an industrial plating facility for a potential purchaser of the property, identifying potential areas of concern.

Polyvinyl Chloride Plant, Lawton, OK. Mr. Chiu performed a Phase I Environmental Site Assessment on a polyvinyl chloride plant (PVC) for a national bank client seeking to identify environmental risk associated with lending on the property.

Airport Refueling Operator, Tulsa, OK and Dallas, TX. Mr. Chiu performed Phase I Environmental Site Assessments on airport refueling centers at international airports in Tulsa, Oklahoma and Dallas, Texas for a potential purchaser of the property, identifying potential areas of concern.

Multi-family

Multi-family, Canon City, Clifton, Buena Vista and Lakewood, CO. Mr. Chiu performed Phase I Environmental Site Assessments and Property Condition Assessments on apartment complexes across the state of Colorado in accordance with the Fannie Mae scope of work.

Multi-family, Tulsa, OK. Mr. Chiu performed Phase I Environmental Site Assessments on apartment complexes in Tulsa, Oklahoma in accordance with the Fannie Mae scope of work.

Multi-family, Little Rock, AR. Mr. Chiu performed Phase I Environmental Site Assessments and Property Condition Assessments on two apartment complexes in Little Rock, Arkansas.

Multi-family, Denton, TX. Mr. Chiu performed a Phase I Environmental Site Assessments on apartment complex in Denton, Texas in accordance with the United States Department of Housing and Urban Development scope of work.

Equity

Office Towers, Honolulu, HI. Mr. Chiu performed Phase I Environmental Site Assessments on four landmark office towers in downtown Honolulu, Hawaii as part of an acquisition for an equity client. The assessments occurred over the course of four days, and included daily briefings and de-briefings with the client.

Historic Office Building, Bentonville, AR. Mr. Chiu performed a Phase I Environmental Site Assessment and a Property Condition Assessment on a historic office building in downtown Bentonville, Arkansas that is home to the original retail location of a large, multi-national retail chain.

Golf Course Portfolio, Grapevine and Mansfield, TX. Mr. Chiu performed a Phase I Environmental Site Assessments on two semi-private golf courses as part of an acquisition for an equity client.

Oil and Gas Industry

Oil and Gas Exploration Yards, Texas, Oklahoma, Louisiana and New Mexico. Mr. Chiu has performed numerous NORM surveys, Phase I Environmental Assessments and Exit Audits for oil and gas exploration properties that include fracking equipment, active and decommissioned wells, machine maintenance, and bulk fuel storage.

Decommissioned Natural Gas Extraction Plant, Andrews, TX. Mr. Chiu performed a Phase I Environmental Site Assessment on a former natural gas extraction plant for a potential purchaser seeking to identify environmental risk associated with the acquisition of the property.

Saltwater Injection Wells, Various Sites, TX. Mr. Chiu performed Phase I Environmental Site Assessments on numerous saltwater injection wells across the state of Texas for an oil and gas exploration service company.

National Radon Proficiency Program (NRPP) Residential Measurement Provider (License No. 108203 RT)

Training

EPA/AHERA - Asbestos in Buildings: Inspection and Assessment
OSHA (Occupational Safety and Health Administration) – 40 hour HAZWOPER

Experience Summary

Ms. Crews serves as a Senior Project Manager for Partner Engineering and Science, Inc. (Partner), and has performed assessments on numerous commercial, multi-family and industrial facilities. Ms. Crews is familiar with all standards of Due Diligence Property Assessments and the needs and requirements of a varied number of reporting standards, including the Phase I Environmental Site Assessment (E1527-13), Fannie Mae, Freddie Mac, Housing and Urban Development (HUD) Multi-Family Accelerated Processing (MAP) and LEAN Guidelines, customized client formats or scopes, along with Phase II Subsurface Investigations, soil and groundwater remediation, regulatory compliance audits, asbestos surveys and indoor air quality studies.

Real estate investors, lenders, and real estate equity funds have come to rely on Ms. Crews' advice and judgment to assist them with their real estate business decisions. Prior to joining Partner, Ms. Crews was a Project Manager in charge of the various Phase I Environmental Site Assessments (ESAs) and Phase II subsurface investigations. In that capacity, she was responsible for all ESAs, subsurface work, report reviews, and client relations.

Additionally, Ms. Crews was also an Environmental Scientist/Project Manager for an environmental/engineering firm where she was an integral member of the team. She performed and managed environmental assessment activities on various industrial, commercial, institutional and residential properties such as air monitoring assessments; and, soil and groundwater investigations. She has also managed environmental planning and permit requirements associated with a variety of environmental assessments such as wetland determinations/delineations; comprehensive asbestos surveys and Operations & Maintenance Plans; and, Spill Prevention, Control & Countermeasure Plans. Additionally, she has prepared applicable reports in formats prescribed by various fiduciary institutions and performed peer reviews on environmental site assessments completed by others.

Project Experience

Mixed-Use Complex, Yonkers, New York. Managed the completion of Phase I Environmental Site Assessment to Fannie Mae protocol, inclusive of an ongoing, extensive subsurface groundwater investigation due to the former presence of a former industrial facility, former gasoline service station and current dry cleaning facility.

Mixed-Use Complex, Milwaukee, Wisconsin. Managed the completion of Phase I Environmental Site Assessment to HUD MAP guidelines and radon measurement activities. The assessment was complicated due to the presence of historical tenants that included a foundry, manufacturing gas light facility and an oil warehouse facility.

Healthcare Facility, Dunkirk, New York. Managed the completion of Phase I Environmental Site Assessment on a healthcare facility, which led to the identification of a formerly closed underground storage tank (UST). Ms. Crews oversaw thorough local and regulatory research to identify that the tank was improperly closed, which led to an extensive and ongoing subsurface investigation. Ms. Crews also developed an Operations and Maintenance program for the management of asbestos-containing materials within the facility.

Gasoline service stations, various locations. Conducted, managed, and/or reviewed Phase I Environmental Site Assessments on operating and closed gasoline service stations throughout the continental United States. Conducted extensive reviews of subsurface investigations to evaluate the potential for the presence of residual contamination or undiscovered contamination to remain in place.

Affiliations

The American Association of Radon Scientists and Technologists (AARST)

Speaking

Prudential Mortgage Capital Company (PMCC), Consultant Conference, Charleston, South Carolina, 2015
Ms. Crews presented an overview of the proposed new DRAFT HUD MAP Guide, to include radon testing protocols and the capital needs assessment electronic tool (CAN e-Tool) to colleagues, and peers.

SunTrust Bank, Inc., Team Meeting, Webinar, Charlotte, North Carolina, 2015
Ms. Crews presented a webinar outlining radon guidelines to include testing, result interpretation and mitigation measures and alternatives.

BRRTS = Bureau of Remediation and Redevelopment Tracking System

2.0 Introduction

This section presents background information, a summary of previous environmental activities or studies, and information on the regional physiographic, geologic, and hydrogeologic conditions.

2.1 BACKGROUND INFORMATION

The Property consists of three parcels comprising approximately 3.22 acres to the north and west of Fox Shores Drive within a mixed commercial and residential area of Kaukauna, Wisconsin. The Property is currently occupied by Fox Shores Apartments for residential use. Current improvements on the Property consist of apartment buildings with paved parking areas and landscaping. Site location and layout are shown on Figures 1 and 2.

According to historical sources, the Property was developed as early as the 1890s. The Property and vicinity were developed as part of the Chicago and Northwest Railroad Shops. Areas of the Site were formerly utilized as a carpentry shop, machine shop, repair shop, engine room, coal room, blacksmith shop, supply warehouses, tin shop, and pipe shed. In 1983 the Property was redeveloped into multi-family residential apartments along Bicentennial Court. Additional apartments were later developed along Fox Shores Drive in 1992. Stantec understands that Partner Engineering and Science, Inc. (Partner) completed a Phase I Environmental Site Assessment (ESA) at the Property during July 2018. Several recognized environmental conditions (RECs) were identified during the Phase I ESAs; some of which included the following:

- The United States Army Corps of Engineers – Parcel J (Kaukauna Power Canal) is an open Environmental Repair Program case on the Wisconsin Bureau for Redevelopment and Remediation Tracking (WI BRRTS) database. The case exists adjacent to the west of the Property and has been identified with lead impacts in soil;
- Ghost Town Fitness Center located at 180 Fox Shores Drive is adjacent to the Site (east) and is associated with arsenic and selenium groundwater impacts;
- Kaukauna Waste Oil Collection Site located at 201 West 2nd Street, 222 3rd Street, and 3rd Street 200 Block is adjacent to the Site (south) and is associated with petroleum soil and groundwater impacts.

To evaluate the RECs, a Phase II ESA was performed by Partner at the Property in November of 2018. As part of the Phase II ESA, five soil borings were completed for the collection of representative soil and groundwater samples along with the installation of three temporary sub-slab vapor sampling points. The Phase II ESA identified Resource Conservation and Recovery Act (RCRA) metals in soil at concentrations in excess of Wisconsin Administrative Code (Wis. Adm. Code) NR720 residual contaminant levels (RCLs). Polynuclear aromatic hydrocarbons (PAHs) were also detected in the groundwater in excess of the Wis. Adm. Code NR140 preventive action limit (PAL) and/or enforcement standards (ES) at the Site. Finally, dichlorodifluoromethane was detected above Wisconsin Department of Natural Resources (WDNR) residential sub-slab vapor risk screening levels. The Partner Phase II ESA report is included in Appendix G.

On December 3, 2018 Stantec was hired by Fox Investments, LLC to notify the WDNR of soil and groundwater contamination at the Site and possible vapor intrusion of dichlorodifluoromethane into Site buildings. On January 7, 2019, the WDNR opened BRRTS case #02-45-582746 for the Site and requested additional investigation to further characterize and define the extent of contamination at the Site and complete remedial actions needed for Site closure. Due to the potential health threat of vapor intrusion, the WDNR requested that immediate actions be taken to investigate potential vapor intrusion impacts within the apartments at the Site.

On February 25, 2019 Stantec conducted ambient air sampling within three apartment units. On February 26, 2019, Stantec personnel installed three sub-slab vapor points (VP-4, VP-5, and VP-6) within the same

three apartment units where the ambient air samples were collected. An additional vapor point was also installed immediately adjacent to original vapor point (VP-2) from the November 2018 Phase II ESA completed by Partner Engineering and Science, Inc. (Partner).

On August 13, 2019 Stantec conducted additional sub-slab vapor sampling at vapor points VP-4, VP-5, and VP-6 within three apartment units at the Site. Samples were collected within the cooling months of summer to contrast earlier samples collected during the heating months of winter. Vapor samples were again sampled for dichlorodifluoromethane using Environmental Protection Agency (EPA) method TO-15.

With elevated dichlorodifluoromethane sub-slab concentrations at the Site, a source for the contamination was investigated. In order to determine a source for the sub-slab vapor issues at the Site, soil and groundwater investigation activities were conducted across the Site from May 2019 to April 2020. Interspersed pieces of foundry slag, and/or coal were identified in many of the borings from two to four feet below ground surface (bgs) and likely represents historic urban fill.

Due to the lack of dichlorodifluoromethane in soil samples collected at the Site, Stantec and the property owner continued to search for potential sources for the vapor intrusion issues. Upon further investigation, it was discovered that extruded polystyrene foam board was used as insulation on the interior foundation walls of the apartment buildings. It was further determined that dichlorodifluoromethane was a component that made up the extruded polystyrene foam insulation.

After determining that the extruded polystyrene foam board used on the apartment building's foundation walls could potentially be the source of the vapor intrusion issues at the Site, discussions were conducted with the DNR. During those discussions, it was determined that construction/building materials are unregulated and that a subsequent release from these materials would not warrant further vapor assessment or require remedial action to be conducted.

Further investigation, however, was warranted to characterize and define the extent of soil and groundwater contamination and aid the creation of a remedial action plan for the Site. To meet assessment requirements by the WDNR, field sampling, laboratory, and investigative activities were performed in accordance to the WDNR approved site investigation workplan submitted to the WDNR April 16, 2019 (Stantec, 2019).

2.2 REGIONAL PHYSIOGRAPHY, GEOLOGY, AND HYDROGEOLOGY

According to the Wisconsin Geological and Natural History Survey (WGNHS), the regional surface geology is described as glacial till of the Glenmore Member of the Kewaunee Formation, deposited by ice of the western part of the Green Bay Glacial Lobe during Wisconsin's last glaciation (WGNHS, 2011). Glacial soils in this area consist of varying amounts of silt and clay with lesser amounts of sand. The Glenmore member is the surficial unit in the very southeastern places in Outagamie County east of the Fox River; however, it is sporadically overlain by lacustrine silt or clay of younger and/or unnamed units (Mickelson et. al. 1984). Results of the SI identified native and non-native soils at the Site.

The bedrock in Outagamie County typically consists of dolomite, limestone, and shale of the Galena Formation of the Sinnipee Group (Luczaj, 2011). Depth to bedrock is estimated to exist between 5 and 50 feet below grade (fbg). Bedrock was believed to be encountered during this investigation of the Property.

The shallow water table is often a subdued expression of surface topography. Shallow groundwater in unconsolidated glacial sediments generally flows from areas of groundwater recharge, such as hills and broad uplands, to areas of groundwater discharge, such as wetlands, rivers, and lakes. Based on the local surface topography, regional shallow groundwater is expected to flow southeast along the Fox River. Other man-made features such as wells, roads, filled areas, buried utility lines, sewers, and drainage ditches may alter the natural shallow groundwater flow direction. The depth to groundwater was observed in site monitoring wells from approximately 3.5 to 6 fbg.

Potable water at the Site is obtained from the City of Kaukauna municipal water system which is supplied by five groundwater wells located throughout the city. Depths of the wells range from 500 to 850 feet deep.

3.0 Investigation Rationale and Methodology

This section presents details for the methods of investigation used during the SI.

3.1 SCOPING INFORMATION

The SI was focused on assessing known or potential environmental concerns discovered at the Site during the previous Phase II ESA. These concerns included:

1. Further evaluating potential vapor intrusion impacts within the apartments at the Site.
2. Further characterize and define the extent of soil and groundwater contamination at the Site and complete remedial actions needed for Site closure.

To address these concerns, 27 soil borings, 4 sub-slab vapor points, and 5 temporary monitoring wells were installed on the Site to define the extent of known contamination identified during the previous investigative work.

3.2 SEQUENCE OF ACTIVITIES

The sequence of activities performed as part of the SI are summarized below.

	Dates	Activity Description
Site Investigation Schedule	10/03/2018	Phase II ESA initiated by Partner Engineering and Science, Inc. with the completion of borings (B1 through B5), installation of vapor sampling points (VP-1 through VP-3), and installation of temporary monitoring wells (B1-GW through B5-GW). (See Appendix G)
	02/25/2019	Ambient air sampling completed in three of the apartment buildings on-site.
	02/26/2019	Collect ambient air samples from apartments. Install and sample sub-slab vapor points (VP-4, VP-5, VP-6) in apartments in which ambient air samples were collected. Install and sample sub-slab vapor point (VP-2R) in water softener shed.
	05/14/2019	Completion of hand auger borings (SB6 through SB10-1).
	08/13/2019	Sample sub-slab vapor points (VP-4, VP-5, VP-6).
	08/21/2019	Completion of borings (SB10-2 through SB17) and installation of temporary monitoring wells (TW10, TW11, TW13, TW15, and TW17). Complete survey and development of temporary wells.
	08/28/2019	Groundwater samples and elevations collected from temporary monitoring wells (TW10, TW11, TW13, TW15, and TW17).
	04/15/20	Complete hand auger borings (HA-1 through HA-14).
	04/16/2020	Groundwater samples and elevations collected from temporary monitoring wells (TW10, TW11, TW13, TW15, and TW17).

3.3 SUB-SLAB VAPOR POINT INSTALLATION AND AIR SAMPLING

On February 25, 2019 Stantec conducted ambient air sampling within three apartment units. On February 26, 2019, Stantec personnel installed three sub-slab vapor points (VP-4, VP-5, and VP-6) within the same three apartment units where the ambient air samples were collected. An additional vapor point was also installed immediately adjacent to original vapor point (VP-2) from the November 2018 Phase II ESA completed by Partner Engineering and Science, Inc. (Partner). Sub-slab vapor point locations can be found on Figure 3. Vapor samples were analyzed for dichlorodifluoromethane using United States Environmental Protection Agency (U.S. EPA) method TO-15.

On August 13, 2019 Stantec conducted additional sub-slab vapor sampling at vapor points VP-4, VP-5, and VP-6 within three apartment units at the Site. Samples were collected within the cooling months of summer to contrast earlier samples collected during the heating months of winter. Vapor samples were again sampled for dichlorodifluoromethane using EPA method TO-15.

3.4 SOIL BORING COMPLETION AND SOIL SAMPLING

Between May 14, 2019 and April 15, 2020, Stantec completed 27 soil borings (SB6 through SB17; HA-1 through HA-14) on the Site by either hand auger or truck mounted GeoProbe® operated by Geiss Soil and Samples, LLC of Merrill Wisconsin. During this time, Stantec personnel collected soil samples from the borings for field screening and laboratory analysis.

Each soil boring was drilled to minimum of 1.5 feet bgs and a maximum depth of 10 feet bgs. Soil was sampled continuously from the ground surface to the total depths explored. Samples were collected for environmental purposes to evaluate if soil and/or groundwater was impacted by previous site uses. Soil boring locations are illustrated on Figure 3. Geologic soil boring logs are presented in Appendix A.

Each soil sampling interval was divided into two aliquots - one used for field screening purposes and one used to supply materials for potential submittal to a laboratory for chemical analysis. The laboratory aliquot for each soil sample was immediately placed in laboratory provided containers, sealed, and placed in a cooler with ice. The other portion of each sample was placed into plastic Ziploc® bags and used for field screening the presence of volatile organic compounds (VOCs) using a photoionization detector (PID) equipped with an 11.7 electronvolt (eV) lamp. All non-disposable soil sampling equipment was washed with a detergent solution and double-rinsed with organic-free tap water before and after each soil sample was collected to prevent sample cross-contamination.

In all borings, the corresponding soil sample(s) exhibiting the highest PID reading or within a specified depth interval was submitted for laboratory analysis for combinations of either VOCs, PAHs, or RCRA metals. Soil samples were submitted under chain-of-custody procedures and analyzed by Eurofins TestAmerica (TA) in Chicago, Illinois.

Soil borings not converted into temporary monitoring wells were immediately abandoned in accordance with Chapter NR 141.25, WAC by backfilling with bentonite after the completion of drilling and soil sampling. WDNR Borehole Abandonment Forms are presented in Appendix B.

3.5 MONITORING WELL INSTALLATION AND GROUNDWATER SAMPLING

Temporary monitoring wells were installed in five of the soil borings (SB10-2, SB11, SB13, SB15, and SB17) and designated as TW10, TW11, TW13, TW15, and TW17, respectively. The monitoring wells were constructed using 1-inch inner diameter, Schedule 40 polyvinyl chloride (PVC) casing and 10-foot lengths of factory slotted PVC screen (0.010-inch slot) that were positioned to straddle/intersect the water table. Monitoring well locations are shown on Figure 4.

Construction and development of the monitoring wells was conducted in accordance with Chapter NR 141, WAC. Monitoring well sampling was conducted in accordance with WDNR guidance (WDNR, 1996). WDNR Monitoring Well Construction and Well Development Forms are included as Appendix C. The location of each monitoring well was documented using a GPS with the vertical height of the ground

surface and riser elevation surveyed at each monitoring well location. Groundwater samples were collected from the Site monitoring wells on August 28, 2019 and April 16, 2020 using low flow sampling techniques. As part of the groundwater sample collection process, observations were specifically made for the presence of oil droplets or a petroleum sheen, which could indicate the presence of a floating layer of Light Non-Aqueous Phase Liquids (LNAPLs). No evidence for the presence of LNAPLs was observed by Stantec personnel at any of the monitoring wells.

The groundwater removed from the wells was carefully poured into pre-cleaned sample bottles provided by Eurofins TA Laboratories. The bottles were prepared with pre-measured chemical preservatives by the analytical laboratory (i.e., hydrochloric acid for VOC samples and nitric acid for metals samples). Care was exercised during sampling to avoid aeration of the samples and loss of preservative. Groundwater samples for dissolved metals analysis were field filtered prior to filling the sample bottles. New disposable filters were used for each sample.

All sample bottles were packed into a cooler with ice immediately after collection and delivered under chain-of-custody procedures directly to Eurofins TA in Chicago, Illinois. The groundwater samples were analyzed for PAHs, VOCs, and RCRA metals.

3.6 SUMMARY OF FIELD, LABORATORY, AND OTHER DATA COLLECTED

Following is a summary of the types of data collected as part of the SI completed by Stantec.

Data Type	Fox Shores Apartments Property
Completed Borings	27 borings
Physical and visual characteristics (soil)	76 samples
PID field screening data (soil)	76 samples
Elevation data (water table surface)	5 wells
Laboratory analyses (soil) – PAHs	26 samples
Laboratory analyses (soil) – VOCs	26 samples
Laboratory analyses (soil) – RCRA Metals	22 samples
Laboratory analyses (water) – PAHs	10 samples
Laboratory analyses (water) – VOCs	10 samples
Laboratory analyses (water) – RCRA Metals	10 samples
Laboratory analyses (ambient air) – VOCs	3 samples
Laboratory analyses (sub-slab vapor) - VOCs	7 samples

4.0 Applicable Clean-up Criteria

Procedures for establishing soil cleanup standards applicable to sites in Wisconsin with documented soil contamination are specified in NR720. Significant revisions to NR720 were implemented in 2013, with an effective date of November 1, 2013. Soil cleanup standards depend in part on current land use and zoning. Based on the current and planned future use of the property for residential or other non-industrial land uses, the more restrictive non-industrial classification is being used to assess cleanup criteria for the property.

RCLs are numerical soil cleanup standards that are calculated for a minimum of two exposure pathways – direct contact by humans with exposed soil and leaching of contaminants from soil into groundwater. The cleanup standard is the lower of the RCLs calculated for a number of exposure pathways. A variety of methods may be used to calculate RCLs, subject to WDNR approval. The approach used for the Fox Shores Apartments Property was to use an RCL spreadsheet developed by the WDNR's Remediation and Redevelopment Program staff for use by consultants. The spreadsheet (WDNR, 2018) is updated periodically by WDNR staff and utilizes toxicity information maintained on the U.S. EPA Regional Screening Level website: http://www.epa.gov/reg3hwmd/risk/human/rb-concentration_table/index.htm. As toxicity data are updated periodically for different types of contaminants, the WDNR RCL spreadsheet is similarly updated. The soil laboratory analytical tables included with this report have been updated to reflect the recently updated December 2018 RCLs.

As part of the revisions to NR720, WDNR adopted use of Background Threshold Values (BTVs) for select metals in soil whose occurrence may be attributable in whole or in part to natural occurrence in Wisconsin soil. BTVs are "non-outlier trace element maximum levels in Wisconsin surface soils" as determined through a state-wide study (USGS, 2011). BTVs were established for 16 metals including aluminum, arsenic, barium, cadmium, calcium, chromium, cobalt, copper, iron, magnesium, lead, manganese, nickel, strontium, vanadium, and zinc. Probably the most significant BTV is the value of 8.0 milligrams per kilogram established for arsenic. This value is significant because the RCLs calculated for the direct contact and groundwater pathways are significantly lower than this value, which in the past resulted in sites with relatively low levels of naturally occurring arsenic significantly exceeding the cleanup levels. If measured levels of arsenic or the 15 other metals for which BTVs have been established are below the BTVs, these levels can be attributed to natural occurrence without the need to perform a WDNR-approved site-specific study to determine background levels. RCL values calculated for the non-industrial direct contact and groundwater protection pathways are included on Tables 2a to 2c. BTVs are included on Table 2a.

Public health-related groundwater quality standards are set forth by NR140. Standards are listed for substances of public health concern (defined as substances having carcinogenic, mutagenic, or teratogenic properties or interactive effects) and substances of public welfare concern (defined as having a negative aesthetic value, but with little threat to human health). Two levels of standards are listed, the PAL and the ES. The ES represents a concentration above which action generally must be taken to improve the quality of groundwater. The PAL represents a lower concentration (usually 10 to 20 percent of the ES) above which groundwater quality should be monitored. PAL and ES concentrations are summarized in Tables 3a, 3b, and 3c.

The term "vapor intrusion pathway" generally refers to subsurface contamination that can move through the air-filled pores of vadose zone soils and enter the breathing space of buildings. WDNR notes that due to their high volatility and health risk, VOCs, particularly chlorinated VOCs and petroleum, are the contaminants that most commonly trigger assessment of the vapor intrusion pathway. Soil vapor results were compared to the U.S. EPA Regional screening levels for residential sites established using the U.S. EPA Vapor Intrusion Screening Level Calculator (VISL) and VISL User Guide as recommended in the WDNR's Guidance for *Addressing Vapor Intrusion at Remediation and Redevelopment Sites in Wisconsin Technical Guidance* dated January 2018.)

5.0 Site Investigation Findings

5.1 SITE HYDROGEOLOGIC CONDITIONS

Subsurface strata encountered in the borings generally consisted of approximately three inches of asphalt or 1.5 to 2 feet of topsoil underlain by 0.5 to 2 feet of fine black sand and gravel underlain by 5 to 6 feet of silty clay. A geologic cross-section of the Site is shown on Figures 8 and 9.

Measured depth to the water table in the five wells installed at the Property ranged from 3.86 feet bgs in TW10 to 6.14 feet bgs in TW15. Due to the moderate to low saturated hydraulic conductivity of the silty clay soil, wells on the Property were able to be purged dry using a peristaltic pump. Based on water levels collected from the wells in August 2019 and April 2020, the local shallow groundwater flow is predominantly to the south away from the Fox River. A summary of the water table elevation data is included in Table 5. Groundwater flow direction is shown on Figure 5.

5.2 NATURE AND EXTENT OF SOIL IMPACTS

All soil samples collected by Stantec as part of the SI, with the exception of HA-1 through HA-14, were field screened for the presence of VOCs using a PID. PID readings ranged across the Site from 0.8 instrument units as isobutylene (iu) to greater than 300 iu. Petroleum odors were noted in several of the borings at the time of field screening. The PID data is summarized on Table 1 as well as included on the soil boring logs presented in Appendix A.

Laboratory analysis of shallow soil samples (0-4 feet bgs) collected from the Site detected multiple RCRA metals, and PAHs exceeding the NR720 RCLs for groundwater protection and/or non-industrial direct contact. Benzo(a)pyrene, arsenic, lead and mercury were also detected in soil above the industrial direct contact RCL. Based on the sampling results, it appears detected contaminants are likely related to historic urban fill on the Property since contaminant concentrations generally decrease when native soils are encountered.

In addition, during soil investigation activities, VOCs did not appear to be prevalent in soil at the Site, as no exceedances were detected in soil samples collected with the exception of benzene above the RCL for groundwater protection in soil borings SB6, HA-4, HA-5, and HA-8 and trimethylbenzenes in SB15 and SB17. Methylene chloride was also detected in several soil samples above the RCL for groundwater protection but is considered to be a laboratory contaminant. Dichlorodifluoromethane was not detected within any of the soil samples collected at the Site.

Soil laboratory analytical reports, chain-of-custody forms and laboratory quality assurance/quality control data are presented in Appendix D. Soil laboratory analytical results from the SI fieldwork and previous Phase II ESA are summarized in Tables 2a through 2c.

Based on sampling data provided by this SI, the extent of contamination in soil has been sufficiently defined. PAH and RCRA metal impacted clay and sand/gravel fill appears to extend sitewide and is associated with the presence of historic urban fill. Based on the historic use of the Site and neighboring properties as a railyard, it is assumed that this historic urban fill extends off-site and throughout a large portion of the surrounding area. Therefore, further investigation was not completed beyond the property lines.

In addition, petroleum impacted soils appear to extend sporadically between the apartment buildings north of Bicentennial Court and along landscaped areas adjacent to Bicentennial Court and Fox Shores Drive. The estimated extent of soil containing contamination in excess of RCLs for groundwater protection and direct contact is shown on Figure 6.

5.3 NATURE AND EXTENT OF GROUNDWATER IMPACTS

Three rounds of groundwater sampling were completed at the Site between the initial Phase II ESA and the site investigation. Groundwater analysis of water samples collected at the Property detected arsenic in three of the five temporary monitoring wells exceeding their respective NR 140 PALs. Benzo(a)pyrene, benzo(b)fluoranthene, and/or chrysene were also identified within three temporary monitoring wells above the PAL with benzo(a)pyrene and benzo(b)fluoranthene above the ES during the most recent round of sampling at TW17. PAH contamination in groundwater likely appears to be a product of fine sediment resulting from silty clay and sandy soils found at the Site along with the limitations of temporary monitoring wells. This is what likely can be seen at TW17 where no exceedances existed within the initial sampling by Stantec and no detections being found while sampling temporary well B1-GW directly adjacent to it. No VOCs were detected in groundwater samples collected exceeding either the PAL or ES.

The results of the SI indicate that the extent of groundwater impacts is sufficiently defined. Based on sampling results, it does not appear that contaminants in soil are significantly affecting groundwater quality at the Property. Arsenic remains above the PAL within three of the temporary monitoring wells on-site. Additionally, benzo(a)pyrene and benzo(b)fluoranthene also remain just above the ES in temporary monitoring well TW17. However, the PAH contamination in groundwater likely appears to be a product of fine sediment resulting from silty clay and sandy soils found at the Site along with the limitations of temporary monitoring wells. A map depicting the estimated extent of groundwater contamination is included as Figure 7. Groundwater results for the SI are presented on Tables 3a through 3c. Laboratory analytical reports for groundwater samples are presented in Appendix E.

5.4 MIGRATION PATHWAYS AND POTENTIAL RECEPTORS

As part of the SI, Stantec evaluated potential contaminant migration pathways at the Site and the findings are summarized below.

5.4.1 Groundwater/Surface Water Impacts

Groundwater impacts at the Site appear to be minimal with soil contaminants not significantly affecting groundwater quality. Due to the low concentrations detected in the groundwater, it does not appear surface water or sediment is likely to be impacted as the result of this release. Further, water for the Site is provided by the City of Kaukauna's municipal water system which receives its supply from five municipal wells throughout the city. The closest municipal well to the Site is north of the Fox River and in excess of 1,600 feet to the Site.

5.4.2 Utilities

During the SI a limited number of underground utilities were identified at the Site. Buried electric lines run across the Site from transformers to each of the apartment buildings. It is not anticipated that buried electric lines would serve as a conduit for contaminant migration since these lines are typically backfilled with the same material which was removed from the utility trench or horizontally bored. In addition, water, storm, and sanitary sewer lines were also noted along Fox Shores Drive and Bicentennial Court. Given the fact that soil contaminants on-site do not appear to be affecting groundwater quality, it does not appear likely that contamination is migrating along utilities to or from the site.

5.4.3 Vapor Intrusion

The term "vapor intrusion pathway" generally refers to subsurface contamination that can move through the air-filled pores of vadose zone soils and enter the breathing space of buildings. WDNR notes that due to their high volatility and health risk, VOCs, particularly chlorinated VOCs and petroleum, are the contaminants that most commonly trigger assessment of the vapor intrusion pathway.

On December 3, 2018 Stantec notified the WDNR of soil and groundwater contamination at the Site and possible vapor intrusion of dichlorodifluoromethane into Site buildings. On January 7, 2019, the WDNR opened BRRTS case #02-45-582746 for the Site and requested additional investigation to further characterize and define the extent of contamination at the Site and complete remedial actions needed for Site closure. Due to the potential health threat of vapor intrusion, the WDNR requested that immediate actions be taken to investigate potential vapor intrusion impacts within the apartments at the Site.

On February 25, 2019 Stantec conducted ambient air sampling within three apartment units. On February 26, 2019, Stantec personnel installed three sub-slab vapor points (VP-4, VP-5, and VP-6) within the same three apartment units where the ambient air samples were collected. An additional vapor point was also installed immediately adjacent to original vapor point (VP-2) from the November 2018 Phase II ESA completed by Partner. Sub-slab vapor point locations can be found on the attached Figure 3. Vapor samples were analyzed for dichlorodifluoromethane using U.S. EPA method TO-15. Based on results from the air sampling, dichlorodifluoromethane exceeded the target residential sub-slab vapor concentration limit in two of the vapor points (VP-6 and VP-2R). However, dichlorodifluoromethane was not detected above target residential indoor air concentration limits. While dichlorodifluoromethane vapors were determined to be present at the Site, their presence did not affect ambient air quality within the apartments in which sampling was conducted.

On August 13, 2019 Stantec conducted additional sub-slab vapor sampling at vapor points VP-4, VP-5, and VP-6 within three apartment units at the Site. Samples were collected within the cooling months of summer to contrast earlier samples collected during the heating months of winter. Vapor samples were again sampled for dichlorodifluoromethane using EPA method TO-15.

Based on results from the additional air sampling, dichlorodifluoromethane exceeded the target residential sub-slab vapor concentration limit in vapor points VP4, VP-5, and VP-6. Results indicated an increase in sub-slab vapor concentrations at each of the sampling points over results of previous samples collected during the heating months of winter. Air quality results for the SI are presented on Tables 4. Laboratory analytical reports for air samples are presented in Appendix F.

With elevated dichlorodifluoromethane sub-slab concentrations at the Site, a source for the contamination was investigated. Due to the lack of dichlorodifluoromethane in soil samples collected at the Site, Stantec and the property owner continued to search for potential alternative options as to a source for the vapor intrusion issues. A release from the air conditioning was ruled out as a source since each apartment is supplied with its own window mounted unit. Any potential release of dichlorodifluoromethane from these units would readily off gas to the atmosphere.

Upon further investigation, it was discovered that extruded polystyrene foam board was used as insulation on the interior foundation walls of the apartment buildings. It was further determined that dichlorodifluoromethane is a component that makes up the extruded polystyrene foam insulation. Therefore, the insulation would be the active source for the dichlorodifluoromethane seen within the sub-slab vapor samples collected. In addition, it was noted that the building design shows the placement of a 4 mil. polyethylene vapor barrier beneath the concrete floor of the buildings. This is likely the reason that dichlorodifluoromethane concentrations did not exceed regulatory limits on ambient air samples collected from the apartments while sub-slab vapor concentrations were detected well in excess of sub-slab vapor limits. Schematics for the apartment buildings along with a materials safety data sheet for the polystyrene foam board insulation are included in Appendix H.

After determining that the extruded polystyrene foam board used on the apartment building's foundation walls was the likely source of the vapor intrusion issues at the Site, discussions were conducted with the DNR. During those discussions, it was determined that construction/building materials are unregulated and that a subsequent release from these materials would not warrant further vapor assessment or require remedial action to be conducted.

6.0 Conclusions, Recommendations, and Limitations

6.1 CONCLUSIONS AND RECOMMENDATIONS

The results of the Phase II ESA and Site Investigation indicate that widespread historic urban fill consisting of clay and sand/gravel is present across the Property at depths of up to 3 feet bgs. The sand and gravel fill are underlain by native silty clay. Laboratory analysis of soil samples collected from the Site reported RCRA metals, PAHs, and select VOCs exceeding Chapter NR 720 Wisconsin Administrative Code RCLs for protection of groundwater. Various RCRA metals and PAHs were also detected in some samples above their respective industrial and non-industrial direct contact RCLs. Based on sampling data provided by this SI, the extent of contamination in soil has been sufficiently defined.

Overall, three rounds of groundwater sampling were completed at the Site. Groundwater analysis of water samples collected at the Property detected arsenic in three of the five temporary monitoring wells exceeding their respective NR 140 PALs. Benzo(a)pyrene, benzo(b)fluoranthene, and/or chrysene were also identified within three temporary monitoring wells above the PAL with benzo(a)pyrene and benzo(b)fluoranthene above the ES during the most recent round of sampling at TW17. PAH contamination in groundwater likely appears to be a product of fine sediment resulting from silty clay and sandy soils found at the Site along with the limitations of temporary monitoring wells. This is what likely can be seen at TW17 where no exceedances existed within the initial sampling by Stantec and no detections being found while sampling temporary well B1-GW directly adjacent to it. No VOCs were detected in groundwater samples collected exceeding either the PAL or ES. Based on sampling results, it does not appear that contaminants in soil are significantly affecting groundwater quality at the Property. Therefore, no further groundwater monitoring appears to be necessary.

Dichlorodifluoromethane was detected above WDNR residential sub-slab vapor risk screening levels during the Phase II investigation completed by Partner in November 2018. Further site investigation activities to locate a source of the vapor intrusion issue concluded that no dichlorodifluoromethane was detected within any of the soil samples collected at the Site. After determining that the extruded polystyrene foam board used on the apartment building's foundation walls was the likely source of the vapor intrusion issues at the Site, no further investigation was warranted since construction/building materials are unregulated, would not warrant further vapor assessment, and their presence would not require remedial action.

On behalf of Fox Investments LLC (Tom Vandeyacht), Stantec is requesting WDNRs concurrence that the site investigation is complete and that the WDNR agrees with the proposed next step which includes remedial action activities to address remaining soil impacts.

6.2 LIMITATIONS

The SI was performed in accordance with generally accepted practices for the environmental consulting profession, undertaking similar studies at the same time and in the same geographical area as the work conducted by Stantec. Stantec observed the degree of care and skill that are generally exercised by the profession under similar circumstances and conditions. No other warranty is expressed or implied.

Stantec's observations, findings, and opinions should not be considered as scientific certainties, but only as opinion based on our professional judgment concerning the significance of the data gathered during this investigation. Specifically, Stantec cannot represent that the Site does not contain any hazardous or toxic materials or other latent conditions beyond that observed by Stantec during the investigation. Additionally, due to limitations of this investigation process and the necessary use of data furnished by others, Stantec and its subcontractors cannot assume liability if actual conditions differ from the information presented in this report.

Key:

RCRA = Resource Conservation and Recovery Act

<x = compound not detected to a detection limit of x

XXX = exceeds WDNR Non-Industrial RCL for direct contact risk

XXX = exceeds WDNR Industrial RCL for direct contact risk

XXX = exceeds WDNR RCL for protection of groundwater

mg/kg = milligram per kilogram

NE = not established by WAC (Wis. Adm. Code) or WDNR Soil RCL Summary Table

"J" = analyte detected between the limit of detection and limit of quantification

RCL = residual contaminant level

fbg = feet below ground

= Boring completed and sample collected by Partner Engineering and Science, Inc.

Notes: WDNR soil RCL Summary table (December 2018) used to establish RCLs for groundwater protection and direct contact.

For the purpose of this evaluation under ch. NR 700, background threshold values are being considered as representative of background conditions.

However, constituent concentrations less than background threshold values may represent a potential health risk if concentrations are greater than health-based standards.

Key:

<x = compound not detected to a detection limit of x
XXX = exceeds WDNR Non-Industrial RCL for direct contact risk
XXX = exceeds WDNR Industrial RCL for direct contact risk
XXX = exceeds WDNR RCL for protection of groundwater
µg/kg = microgram per kilogram
RCL = residual contaminant level
fbg = feet below ground
= Boring completed and sample collected by Partner Engineering and Science, Inc.

Notes: WDNR soil RCL Summary table (December 2018) used to establish RCLs for groundwater protection and direct contact.

Note:

NSL = no screening level assigned from EPA Region 3 Screening Level Table - Residential Air, November 2017

* = screening levels from USEPA Region 3 Screening Level Table - November 2017 and, if applicable, representing 1 in 100,000 cancer risk

x = analyte exceeds applicable target air concentration

= Sample collected by Partner Engineering and Science Inc.

Table 5 - Water Level Elevations, Fox Shores Apartments, 400 Fox Shores Drive, Kaukauna, Wisconsin

Well I.D.	Ground Surface Elevation (site datum)	Reference Point Elevation (site datum)	Top / Bottom Well Screen Elevation (fbg)	Date	Depth to Water (feet)		Water Table Elevation (feet)
					Below Grade	Below Riser	
TW10	98.59	98.46	3-10	8/21/2019	4.20	4.07	94.39
				8/28/2019	4.02	3.89	94.57

Soil Boring Logs

Boring Number:	B1				Page 1 of 5
Location:	Southeastern portion of the subject property			Date Started:	10/3/2018
Site Address:	400 Fox Shores Drive			Date Completed:	10/3/2018
	Kaukauna, Wisconsin 54130			Depth to Groundwater:	7' bgs
Project Number:	18-215232.3			Field Technician:	L. Martin
Drill Rig Type:	Track-mounted GeoProbe 6610DT			**Partner Engineering and Science**	
Sampling Equipment:	five foot Macrocore			805 N. Milwaukee Ave., Ste. 401	
Borehole Diameter:	2.25 inch			Chicago, Illinois 60642	

Depth	Sample	PID	USCS	Description	Notes
1	B1 (0.5-1)		--	Organic topsoil	3/5 recovery (sample volume collected for metals analysis)
2		0.0		Black clay with some sand and gravel, medium-soft, moist	
3					
4		0.0			
5					
6		0.0	CL		5/5 recovery
7	B1 (6-7)			Brown clay with some sand and gravel, medium-soft, wet	(sample volume collected for VOCs and PAHs analysis)
8		0.0			
9				Brown clay with some sand and gravel, medium-soft, moist	
10		0.0			
11				Borehole termintated at 10 feet bgs. Temporary 3/4 inch groundwater monitoring well installed to 10 feet, screend 5 to 10 feet. Groundwater sample B1-GW collected and borehole abandoned with chipped bentonite and patched to mach existing groundcover on 10/3/18.

3. Filled & Sealed Well / Drillhole / Borehole Information

☐ Monitoring Well
☐ Water Well
☒ Borehole / Drillhole

Original Construction Date (mm/dd/yyyy): 05/14/2019

If a Well Construction Report is available, please attach.

Construction Type:
☐ Drilled ☐ Driven (Sandpoint) ☐ Dug
☒ Other (specify): Hand Auger

Formation Type:
☒ Unconsolidated Formation ☐ Bedrock

Total Well Depth From Ground Surface (ft.)	Casing Diameter (in.)
—	—

Lower Drillhole Diameter (in.)	Casing Depth (ft.)
3	—

Was well annular space grouted? ☐ Yes ☐ No ☐ Unknown

If yes, to what depth (feet)?	Depth to Water (feet)

4. Pump, Liner, Screen, Casing & Sealing Material

Pump and piping removed?	☐ Yes	☐ No	☒ N/A
Liner(s) removed?	☐ Yes	☐ No	☒ N/A
Liner(s) perforated?	☐ Yes	☐ No	☒ N/A
Screen removed?	☐ Yes	☐ No	☒ N/A
Casing left in place?	☐ Yes	☐ No	☒ N/A
Was casing cut off below surface?	☐ Yes	☐ No	☒ N/A
Did sealing material rise to surface?	☒ Yes	☐ No	☐ N/A
Did material settle after 24 hours?	☐ Yes	☒ No	☐ N/A
If yes, was hole retopped?	☐ Yes	☐ No	☒ N/A
If bentonite chips were used, were they hydrated with water from a known safe source?	☐ Yes	☐ No	☒ N/A

Required Method of Placing Sealing Material
☐ Conductor Pipe-Gravity ☐ Conductor Pipe-Pumped
☐ Screened & Poured (Bentonite Chips) ☒ Other (Explain): Gravity

Sealing Materials
☐ Neat Cement Grout ☐ Concrete
☐ Sand-Cement (Concrete) Grout ☒ Bentonite Chips

For Monitoring Wells and Monitoring Well Boreholes Only:
☐ Bentonite Chips ☐ Bentonite - Cement Grout
☐ Granular Bentonite ☐ Bentonite - Sand Slurry

5. Material Used to Fill Well / Drillhole

	From (ft.)	To (ft.)	No. Yards, Sacks Sealant or Volume (circle one)	Mix Ratio or Mud Weight
Bentonite	Surface	2.3	0.11 Ft³

Complete Soil Sampling	_ _ _ _ _

3. Filled & Sealed Well / Drillhole / Borehole Information

☐ Monitoring Well ☐ Water Well ☒ Borehole / Drillhole

Original Construction Date (mm/dd/yyyy): 04/15/2020

If a Well Construction Report is available, please attach.

Construction Type:
☐ Drilled ☐ Driven (Sandpoint) ☐ Dug ☒ Other (specify): Hand Augers

Formation Type:
☒ Unconsolidated Formation ☐ Bedrock

Total Well Depth From Ground Surface (ft.)	Casing Diameter (in.)
—	—

Lower Drillhole Diameter (in.)	Casing Depth (ft.)
	—

Was well annular space grouted? ☐ Yes ☐ No ☐ Unknown

If yes, to what depth (feet)?	Depth to Water (feet)

2. Facility / Owner Information

Facility Name: Fox Shores Apartments

Facility ID (FID or PWS):

License/Permit/Monitoring #:

Original Well Owner: Tom Vandeyacht - Fox Investments LL

Present Well Owner: SAME

Mailing Address of Present Owner: 2220 N Lynndale Drive

City of Present Owner	State	ZIP Code
Appleton	WI	54914

4. Pump, Liner, Screen, Casing & Sealing Material

Pump and piping removed?	☐ Yes	☐ No	☒ N/A
Liner(s) removed?	☐ Yes	☐ No	☒ N/A
Liner(s) perforated?	☐ Yes	☐ No	☒ N/A
Screen removed?	☐ Yes	☐ No	☒ N/A
Casing left in place?	☐ Yes	☐ No	☒ N/A
Was casing cut off below surface?	☐ Yes	☐ No	☒ N/A
Did sealing material rise to surface?	☒ Yes	☐ No	☐ N/A
Did material settle after 24 hours?	☐ Yes	☒ No	☐ N/A
If yes, was hole retopped?	☐ Yes	☐ No	☒ N/A
If bentonite chips were used, were they hydrated with water from a known safe source?	☐ Yes	☐ No	☒ N/A

Required Method of Placing Sealing Material
☐ Conductor Pipe-Gravity ☐ Conductor Pipe-Pumped ☐ Screened & Poured (Bentonite Chips) ☒ Other (Explain): Gravity

Sealing Materials
☐ Neat Cement Grout ☐ Concrete ☐ Sand-Cement (Concrete) Grout ☒ Bentonite Chips

For Monitoring Wells and Monitoring Well Boreholes Only:
☐ Bentonite Chips ☐ Bentonite - Cement Grout ☐ Granular Bentonite ☐ Bentonite - Sand Slurry

5. Material Used to Fill Well / Drillhole

	From (ft.)	To (ft.)	No. Yards, Sacks Sealant or Volume (circle one)	Mix Ratio or Mud Weight
Bentonite	Surface	1.7	0.07 ft³

MONITORING WELL CONSTRUCTION
Form 4400-113A Rev. 7-98

Facility/Project Name: Fox Shores Apartments	Local Grid Location of Well ☐ ft. ☐N. ☐S. ☐ ft. ☐E. ☐W.	Well Name: TW 10
Facility License, Permit or Monitoring No.	Local Grid Origin ☐ (estimated: ☐) or Well Location ☐ Lat. 44.280983 Long. -88.275825 or	Wis. Unique Well No. / DNR Well ID No.
Facility ID	St. Plane ft. N, ft. E. S/C/N	Date Well Installed: 08/21/2019 (m m d d y y y y)
Type of Well: Well Code 11 / MW	Section Location of Waste/Source: SE 1/4 of NE 1/4 of Sec. 23, T. 21 N, R. 18 ☒E ☐W	Well Installed By: Name (first, last) and Firm: Geiss Soil & Samples LLC; Dassin Prentice
Distance from Waste/Source ft. / Enf. Stds. Apply ☐	Location of Well Relative to Waste/Source: u ☐ Upgradient s ☐ Sidegradient d ☐ Downgradient n ☐ Not Known	Gov. Lot Number

A. Protective pipe, top elevation _____ ft. MSL

B. Well casing, top elevation _____ ft. MSL

C. Land surface elevation _____ ft. MSL

D. Surface seal, bottom _____ ft. MSL or 0 ft.

12. USCS classification of soil near screen:
GP ☐ GM ☐ GC ☐ GW ☐ SW ☐ SP ☐
SM ☐ SC ☐ ML ☐ MH ☐ CL ☐ CH ☐
Bedrock ☐

13. Sieve analysis performed? ☐ Yes ☒ No

14. Drilling method used: Rotary ☐ 50
Hollow Stem Auger ☐ 41
Geoprobe Other ☒

15. Drilling fluid used: Water ☐ 02 Air ☐ 01
Drilling Mud ☐ 03 None ☒ 99

16. Drilling additives used? ☐ Yes ☒ No

Describe —

17. Source of water (attach analysis, if required):
—

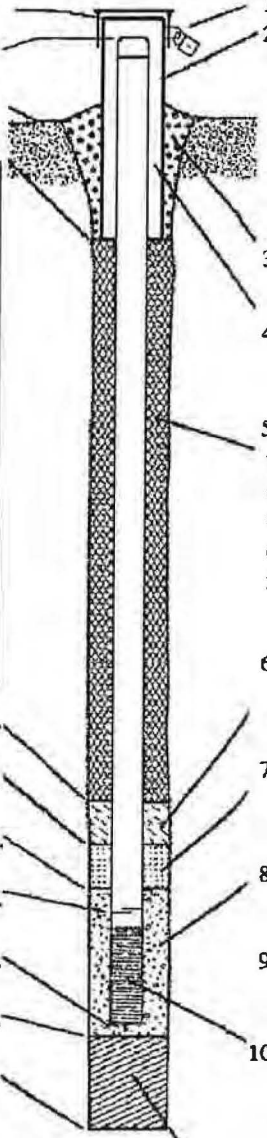
E. Bentonite seal, top _____ ft. MSL or 0.5 ft.

F. Fine sand, top _____ ft. MSL or 1.5 ft.

G. Filter pack, top _____ ft. MSL or 2 ft.

H. Screen joint, top _____ ft. MSL or 3 ft.

I. Well bottom _____ ft. MSL or 10 ft.



J. Filter pack, bottom _____ ft. MSL or 10 ft.

K. Borehole, bottom _____ ft. MSL or 10 ft.

L. Borehole, diameter 2 in.

M. O.D. well casing 1.3 in.

N. I.D. well casing 1.03 in.

1. Cap and lock? ☐ Yes ☐ No

2. Protective cover pipe:
a. Inside diameter: 4 in.
b. Length: 1 ft.
c. Material: Steel ☐ 04 Other ☒
d. Additional protection? ☐ Yes ☒ No
If yes, describe: —

3. Surface seal: Bentonite ☒ 30 Concrete ☐ 01 Other ☐

4. Material between well casing and protective pipe: Bentonite ☒ 30 Other ☐

5. Annular space seal: a. Granular/Chipped Bentonite ☒ 33
b. _____ Lbs/gal mud weight . . . Bentonite-sand slurry ☐ 35
c. _____ Lbs/gal mud weight . . . . . Bentonite slurry ☐ 31
d. _____ % Bentonite . . . . . Bentonite-cement grout ☐ 50
e. _____ Ft^3 volume added for any of the above
f. How installed: Tremie ☐ 01 Tremie pumped ☐ 02 Gravity ☒ 08

6. Bentonite seal: a. Bentonite granules ☐ 33
b. ☐1/4 in. ☐3/8 in. ☐1/2 in. Bentonite chips ☐ 32
c. _____ Other ☐

7. Fine sand material: Manufacturer, product name & mesh size
a. #20 Red Flint
b. Volume added _____ ft^3

8. Filter pack material: Manufacturer, product name & mesh size
a. #40 Red Flint
b. Volume added _____ ft^3

9. Well casing: Flush threaded PVC schedule 40 ☒ 23 Flush threaded PVC schedule 80 ☐ 24 Other ☐

10. Screen material: PVC
a. Screen type: Factory cut ☒ 11 Continuous slot ☐ 01 Other ☐
b. Manufacturer Johnson
c. Slot size: 0.01 in.
d. Slotted length: ____ ft.

11. Backfill material (below filter pack): None ☒ 14 Other ☐

The test results in this report meet all 2003 NELAC and 2009 TNI requirements for accredited parameters, exceptions are noted in this report. This report may not be reproduced except in full, and with written approval from the laboratory. For questions please contact the Project Manager at the e-mail address or telephone number listed on this page.

This report has been electronically signed and authorized by the signatory. Electronic signature is intended to be the legally binding equivalent of a traditionally handwritten signature.

Results relate only to the items tested and the sample(s) as received by the laboratory.

Comments
No additional comments.

Receipt
The samples were received on 5/15/2019 9:10 AM; the samples arrived in good condition, properly preserved and, where required, on ice. The temperature of the cooler at receipt was 2.9º C.

GC/MS VOA
Method(s) 8260B: The method blank for 487277 contained Naphthalene above the method detection limit. This target analyte concentration was less than the reporting limit (RL); therefore,re-analysis of samples was not performed.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

GC/MS Semi VOA
Method(s) 8270D: The following sample was diluted due to the nature of the sample matrix: SB9 0-2 (500-163346-4). Elevated reporting limits (RLs) are provided.

Method(s) 8270D: The following sample required a dilution due to the nature of the sample matrix: SB9 0-2 (500-163346-4). Because of this dilution, the surrogate spike concentration in the sample was reduced to a level where the recovery calculation does not provide useful information.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Metals
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

Organic Prep
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

Qualifiers

GC/MS VOA

Qualifier	Qualifier Description
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

GC/MS Semi VOA

Qualifier	Qualifier Description
E	Result exceeded calibration range.
F1	MS and/or MSD Recovery is outside acceptance limits.
F2	MS/MSD RPD exceeds control limits
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Metals

Qualifier	Qualifier Description
B	Compound was found in the blank and sample.
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
¤	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
PQL	Practical Quantitation Limit
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)

Question	Answer	Comment
Radioactivity wasn't checked or is </= background as measured by a survey meter.	True	
The cooler's custody seal, if present, is intact.	True	
Sample custody seals, if present, are intact.	True	
The cooler or samples do not appear to have been compromised or tampered with.	True	
Samples were received on ice.	True	
Cooler Temperature is acceptable.	True	
Cooler Temperature is recorded.	True	2.9
COC is present.	True	
COC is filled out in ink and legible.	True	
COC is filled out with all pertinent information.	True	
Is the Field Sampler's name present on COC?	True	
There are no discrepancies between the containers received and the COC.	True	
Samples are received within Holding Time (excluding tests with immediate HTs)	True	
Sample containers have legible labels.	True	
Containers are not broken or leaking.	True	
Sample collection date/times are provided.	True	
Appropriate sample containers are used.	True	
Sample bottles are completely filled.	True	
Sample Preservation Verified.	True	
There is sufficient vol. for all requested analyses, incl. any requested MS/MSDs	True	
Containers requiring zero headspace have no headspace or bubble is <6mm (1/4").	N/A	
Multiphasic samples are not present.	True	
Samples do not require splitting or compositing.	True	
Residual Chlorine Checked.	N/A

Comments
No additional comments.

Receipt
The samples were received on 8/23/2019 8:45 AM; the samples arrived in good condition, properly preserved and, where required, on ice. The temperature of the cooler at receipt was 2.7º C.

GC/MS VOA
Methylene chloride was detected in the following samples: SB11 (2-4) (500-168870-2), SB13 (2-4) (500-168870-4), SB14 (0-2) (500-168870-5), SB15 (2-4) (500-168870-6) and SB17 (2-4) (500-168870-9). The method blank associated with these samples was non-detect for Methylene chloride. Methylene chloride is known lab contaminant; therefore all low level detects for this compound should be suspected as lab contamination.

The extraction LCS associated with preparation batch 501507 had several analytes recoveries above control limits. The instrument LCS associated with analytical batch 501589 had all analytes within control limits; therefore re-analysis was not performed. The data have been reported and qualified. SB10 (2-4) (500-168870-1), SB11 (2-4) (500-168870-2), SB12 (2-4) (500-168870-3), SB13 (2-4) (500-168870-4), SB14 (0-2) (500-168870-5), SB15 (4-6) (500-168870-7), SB16 (2-4) (500-168870-8) and SB17 (2-4) (500-168870-9)

The method blank for 501998 contained Naphthalene above the method detection limit and below the Reporting limit (RL). This target analyte concentration were detected in the associated samples; therefore, re-analysis of samples was not performed. Naphthalene results have been flagged in the associated samples with a "B" flag denote the presence in the blank and possible lab contamination.

The laboratory control sample (LCS) for 501998 recovered outside control limits for the following analytes: Bromoform and 1,2-Dibromo-3-chloropropane. These analytes were biased high in the LCS and was not detected in the associated samples; therefore, the data have been reported.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

GC/MS Semi VOA
Method(s) 8270D: The following samples were diluted due to the nature of the sample matrix: SB11 (2-4) (500-168870-2), SB12 (2-4) (500-168870-3), SB16 (2-4) (500-168870-8) and SB17 (2-4) (500-168870-9). Elevated reporting limits (RLs) are provided.

Method(s) 8270D: The following sample required a dilution due to the nature of the sample matrix: SB16 (2-4) (500-168870-8). Because of this dilution, the surrogate spike concentration in the sample was reduced to a level where the recovery calculation does not provide useful information.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Metals
Method(s) 6010C: The low-level CCV at line 69 and ICV at line 16 in 6010C batch 500-502911 was above the method acceptance limits of 70-130% recovery for Cadmium. The sample SB15 (2-4) (500-168870-6) was bracketed. The low-level standard concentration was insignificant compared with the reported sample results and the sample results were unaffected by the bias at that level. The mid-range bracketing the data were all within the 90-110% recovery limits.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Organic Prep
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

Detection Summary

Client: Stantec Consulting Corp.
Project/Site: Fox Shores Apt, Kaukauna 193706620

Job ID: 500-168870-1

Client Sample ID: SB10 (2-4)

Lab Sample ID: 500-168870-1

Qualifiers

GC/MS VOA

Qualifier	Qualifier Description
*	LCS or LCSD is outside acceptance limits.
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

GC/MS Semi VOA

Qualifier	Qualifier Description
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Metals

Qualifier	Qualifier Description
^	ICV,CCV,ICB,CCB, ISA, ISB, CRI, CRA, DLCK or MRL standard: Instrument related QC is outside acceptance limits.
B	Compound was found in the blank and sample.
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
¤	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
PQL	Practical Quantitation Limit
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)

Question	Answer	Comment
Radioactivity wasn't checked or is </= background as measured by a survey meter.	True	
The cooler's custody seal, if present, is intact.	True	
Sample custody seals, if present, are intact.	True	
The cooler or samples do not appear to have been compromised or tampered with.	True	
Samples were received on ice.	True	
Cooler Temperature is acceptable.	True	
Cooler Temperature is recorded.	True	2.7
COC is present.	True	
COC is filled out in ink and legible.	True	
COC is filled out with all pertinent information.	True	
Is the Field Sampler's name present on COC?	True	
There are no discrepancies between the containers received and the COC.	True	
Samples are received within Holding Time (excluding tests with immediate HTs)	True	
Sample containers have legible labels.	True	
Containers are not broken or leaking.	True	
Sample collection date/times are provided.	True	
Appropriate sample containers are used.	True	
Sample bottles are completely filled.	True	
Sample Preservation Verified.	True	
There is sufficient vol. for all requested analyses, incl. any requested MS/MSDs	True	
Containers requiring zero headspace have no headspace or bubble is <6mm (1/4").	N/A	
Multiphasic samples are not present.	True	
Samples do not require splitting or compositing.	True	
Residual Chlorine Checked.	N/A

The test results in this report meet all 2003 NELAC and 2009 TNI requirements for accredited parameters, exceptions are noted in this report. This report may not be reproduced except in full, and with written approval from the laboratory. For questions please contact the Project Manager at the e-mail address or telephone number listed on this page.

This report has been electronically signed and authorized by the signatory. Electronic signature is intended to be the legally binding equivalent of a traditionally handwritten signature.

Results relate only to the items tested and the sample(s) as received by the laboratory.

Comments
No additional comments.

Receipt
The samples were received on 4/17/2020 9:45 AM; the samples arrived in good condition, properly preserved and, where required, on ice. The temperatures of the 2 coolers at receipt time were 0.5º C and 2.6º C.

Receipt Exceptions
A trip blank was submitted for analysis with these samples; however, it was not listed on the Chain of Custody (COC). Added to COC and logged in.

GC/MS VOA
Method 8260B: The laboratory control sample (LCS) for batches 539816 and 539811 recovered outside control limits for Bromomethane. This analyte was biased high in the LCSs and was not detected in the associated samples; therefore, the data have been reported.HA-1 (500-180867-1), HA-2 (500-180867-2), HA-3 (500-180867-3), HA-4 (500-180867-4), HA-5 (500-180867-5), HA-6 (500-180867-6), HA-7 (500-180867-7), HA-8 (500-180867-8), HA-9 (500-180867-9), HA-10 (500-180867-10), HA-11 (500-180867-11), HA-12 (500-180867-12), TW-10 (500-180867-14), TW-11 (500-180867-15), TW-13 (500-180867-16), TW-15 (500-180867-17), TW-17 (500-180867-18) and Trip Blank (500-180867-19)

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

GC/MS Semi VOA
Method 8270D: The following samples were diluted due to the nature of the sample matrix: HA-2 (500-180867-2), HA-3 (500-180867-3), HA-4 (500-180867-4), HA-5 (500-180867-5), HA-6 (500-180867-6), HA-10 (500-180867-10) and HA-11 (500-180867-11). Elevated reporting limits (RLs) are provided.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Metals
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

Field Service / Mobile Lab
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

Organic Prep
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

Qualifiers

GC/MS VOA

Qualifier	Qualifier Description
*	LCS or LCSD is outside acceptance limits.
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

GC/MS Semi VOA

Qualifier	Qualifier Description
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Metals

Qualifier	Qualifier Description
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
¤	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
PQL	Practical Quantitation Limit
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)
